The impact of these deliverables and the alignment they created through a process-oriented preplanning process was tremendous. Project team alignment was accomplished, with the owner adopting a supportive role by having their project manager function as the communication point for the external DB team and also managing the University's internal clients. The Best Value Preplanning Model resulted in significant savings by aligning the project team and identifying and addressing unforeseen risks. Had the team followed a more traditional process and jumped straight into contract, there would have been increased costs that would have driven other changes. Instead, the pre-contract planning methodology enabled the DB team to optimize the functionality of the building. Owner estimates stated that the pre-contract saved 14-18 months in schedule and $8-12 million in cost when compared against traditional processes that would have resulted in change orders during construction.

CONCLUSIONS

The need for more standardized and effective planning processes is present in the current construction industry. Proper preplanning not only enhances project performance in terms of hard dollars, schedule, and quality, yet many owners and contractors lack the expertise or the will to thoroughly perform this important task. The Best Value Preplanning Mode is a pre-contract, process-oriented planning methodology that has been applied in the construction industry and documented to significantly improve project performance. Encouraging case study results suggest that pre-contract planning between owners and contractors may be a viable consideration in the construction industry. More extensive testing and analysis is recommended in order to validate the approach.

IMPLEMENTING HOLISTIC RIGHT OF WAY INFRASTRUCTURE MANAGEMENT: USING INFORMATION TO ELIMINATE BUREAUCRATIC BARRIERS

Brad Carey, PhD[1] and Jason Lueke, PhD[2]

[1] *Department of Construction Management, College of Technology & Computer Science (TECS), East Carolina University, Greenville, NC, United States*

[2]*School of Sustainable Engineering and the Built Environment, Arizona State University, Tempe, AZ, United States*

ABSTRACT

Right of way infrastructure assets (water, sewer, and roads) are declining in performance and facing a deficit in planned maintenance, rehabilitation, and renewal spending that is necessary to ensure satisfactory performance levels. One method to help alleviate the planned spending deficit is to eliminate the traditional planning approach, which suffers from departments that operate in silos. This can be achieved through holistic planning methods that consider water, sewer, and road networks simultaneously when generating maintenance, rehabilitation, and renewal plans in order to generate economies of scale by synchronizing collocated projects from different infrastructure components. In order to achieve organizational change towards holistic right of way infrastructure management, municipal leaders need to utilize dominant information in order to spur a paradigm shift and overcome bureaucratic barriers.

Keywords: Infrastructure Planning, Organizational Change, Evolutionary Algorithm, Maintenance, Rehabilitation

INTRODUCTION

The traditional decision making paradigm associated with the planning of maintenance, rehabilitation, and renewal activities for right of way infrastructure assets (water, sewer, and roads) suffers from the silo effect. The complicated nature of the decision-making process has caused the departments that are responsible for specific infrastructure networks to evolve to a point where they operate in silos. Technical experts that manage these mini-silos have deep expertise and a narrow span of authority (Modemeyer, 2011). Therefore, when projects are conceived, it is almost always within the context of a

[1] careyb@ecu.edu
[2] Jason.lueke@asu.edu

 ISBN: 978-1-84219-840-7 .

particular line of business and disincentives discourage a broader scope: departments do not control other departments' budgets and collaboration can complicate project management and timelines (Antonoff et al. 2009). Figure 1 illustrates the current paradigm where road, sewer and water departments receive their the monies allocated for their infrastructure component's maintenance, rehabilitation, and renewal and proceed to develop their plans without consideration for other utilities.

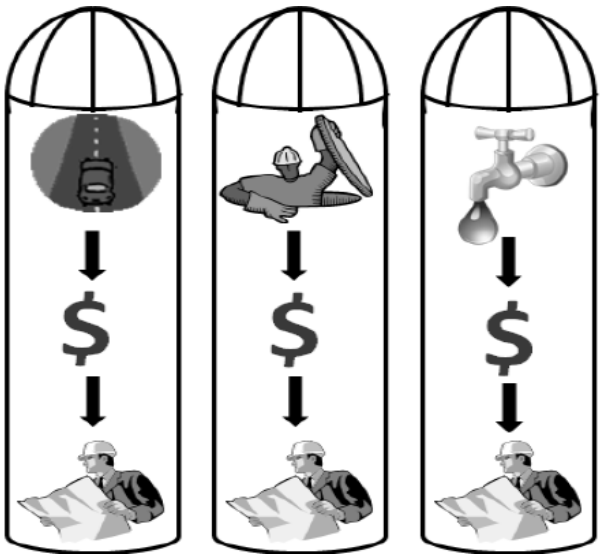

Figure 1. Graphical membership function of the three fuzzy sets

As was identified by Antonoff et al. (2009) the consequences associated with operating in the traditional paradigm is that transportation projects miss opportunities to provide access to utilities and utility projects move on their own timeline without coordination across utilities. Therefore, opportunities for city-wide benefits are not realized because departmental priorities supplant broader priorities (Antonoff et al. 2009). The consequences of missed opportunities for city-wide benefits are exacerbated when you take into account the fact that the Environmental Protection Agency (2008) identified that a significant portion of the nation's infrastructure has reached, or will soon reach, the end of its projected useful life. The American Society of Civil Egineers (2009) identified that the aging right of way infrastructure assets in the United States were facing a substantial shortfall in funding during the subsequent five year period. Road systems were identified as facing a $549.5 billion shortfall in planned spending that was deemed necessary to maintain satisfactory performance levels, while water and sewer systems were identified as facing a combined $108.6 billion shortfall. A paradigm shift that would eliminate the current silo paradigm and create a new paradigm where departments engage in holistic planning, which involves the simultaneous consideration of water, sewer, and roads during planning stages, would help to reduce the shortfall in planned spending.

The need to break out of the current paradigm and adopt an integrated holistic decision-making tool that considers geospatially interdependent infrastructure components has been widely recognized (Halfawy et al., 2002; Lalonde and Bergeron, 2003; Halfawy et

al. 2008; Nafi and Kleiner, 2010; Shahata and Zayed, 2010; Di Sivo and Ladiana, 2011). If a municipality were able to make a shift from the current operating paradigm and adopt a holistic planning model, significant savings can be achieved by synchronizing maintenance, rehabilitation, and renewal activities for collocated road, sewer, and water segments. Nafi and Kleiner (2010) examined three types of economies of scale due to infrastructure adjacency, namely: quantity discount, contiguity discount savings on mobilization costs, and synchronization of pipe replacement with known scheduled roadwork. Project cost savings ranged from a possible 10 percent savings through quantity and contiguity discounts, to 20 cost percent savings when road projects provide access to the utilities beneath.

This research presents a brief overview of the results obtained in the testing of a holistic methodology for planning maintenance, rehabilitation, and renewal of right of way infrastructure assets. Next the paper identifies how those results can be used to overcome bureaucratic boundaries in order to achieve a paradigm shift towards holistic planning. The results presented examined only economics; however, those results indicate that holistic planning has the potential to have a positive effect on all three pillars of sustainability: economics, social impacts, and environmental impacts.

HOLISTIC METHODOLOGY RIGHT OF WAY INFRASTRUCTURE PLANNING

Amongst engineers and researchers, there is a common view that proactive and preventive repair strategies are more effective than the traditional approach of reactive maintenance (Fenner, 2000). This has led to the development of many different methodologies for the planning of maintenance, rehabilitation, and renewal for individual component networks. Most of these methodologies involve the detailed data collection that requires the consumption of time and financial resources, while also being computationally intensive. Planning methodologies for the maintenance, rehabilitation, and renewal of individual road, sewer, and water networks have evolved to the point where most current models employ optimization techniques. Of those optimization techniques, evolutionary and genetic algorithms have moved to the forefront due to their ability to successfully solve or determine near optimal solutions for discontinuous, non-differentiable, non-convex, and multiple peak function optimization problems (Lee et al. 2009). Additionally, evolutionary methods are very effective at searching global solutions and providing multiple solutions (Yang, 2010).

Much research has been conducted into the optimization of planning for single component network maintenance, rehabilitation, and renewal. Examples of planning methodologies that make use of evolutionary or genetic algorithms for water network maintenance, rehabilitation, and renewal include Dandy and Engelhardt (2001), Cheung et al. (2003), Mailhot et al. (2003), Alvisi and Franchini (2006), Dandy and Engelhardt (2006), Giustolisi et al. (2006), Dridi et al. (2009), Haddad et al. (2008), Nafi et al. (2008), Alvisi and Franchini (2010), and Giustolisi and Berardi (2010). Methodologies making use of evolutionary methods for sewer maintenance, rehabilitation, and renewal include Halfawy et al. (2008), Lee et al. (2009), and Yang et al. (2010). Research efforts

 ISBN: 978-1-84219-840-7 .

that applied evolutionary methods in an attempt to optimize planning for roadway maintenance, rehabilitation, and renewal include Fwa et al. (2000), Ferreira et al. (2002), Wu and Flintsch (2009), and Deshpande et al. (2010).

Literature related to the research conducted on singular network optimization revealed that the following three items must be taken into consideration in order to prioritize and optimize maintenance, rehabilitation, and renewal:

- Condition: the actual physical condition of in place segments belonging to the component network.

- Criticality: The importance of each segment within a component network, which includes consideration of a segment's capacity, the area served by a segment, and the segments position within a network (i.e. how many dependant segments).

- Cost/Benefit: The identified cost of any action and the impact that undertaking those costs will have on the network or community.

The authors developed an objective function that utilized the condition ratings and criticality ratings for each segment within a sample network in order to prioritize maintenance, rehabilitation, and renewal. The objective function was designed to be holistic in nature and consider all three right of way networks simultaneously. The savings percentages identified by Nafi and Kleiner (2010) were applied to collocated segments from different infrastructure components receiving rehabilitation or renewal in the same year. The objective function minimized the average yearly component score (CS) for each segment, where the component score was a sum segment scores (S) for each segment within a given component network. Segment scores for each individual segment were calculated by taking the criticality rating (CR) assigned to that segment and multiplying it by the square of the condition rating (C). Simplified 0-100 scales were used for both CR and C. For criticality rating, a score of zero would indicate and a segment with little importance to the overall conveyance scheme and a score of 100 would indicate a segment that is of the upmost importance. For condition rating, a score of zero would indicate a brand new asset that had yet to suffer any degradation and a score of 100 would indicate an asset that has reached the end of its useful design life and that is suffering in performance. This allowed for the system to be portable and easily applied to any network. Municipalities with already in place condition rating and criticality rating schemes could simply use a conversion rubric when entering condition and criticality scores into the decision making engine. The calculation of yearly component score can be seen in Equation 1. The formula for segment score is seen in Equation 2. Equation 3 shows the holistic objective function.

 ISBN: 978-1-84219-840-7 .

(1)

(2)

(3)

The component scores in the objective function were minimized by identifying and prescribing predetermined maintenance, rehabilitation, and renewal actions to individual segments over a defined planning horizon. Each action that was prescribed had a defined cost and impact on the condition rating for the given segment. The costs that were

applied were based on historical costs from publicly funded projects in the State of Arizona. Using a five-year planning horizon, the authors applied the objective function to a right of way network in Tucson Arizona. The holistic objective function was tested for its ability to prescribe superior plans to the traditional paradigm where component networks are considered in isolation. The holistic objective function was tested across three different budgets representing different levels of available financing (Low, Medium, and High), and solved using the evolutionary algorithm within Frontline Systems, Inc. Premium Solver Platform. Twenty optimization runs were conducted for the holistic objective function and compared to the results of individual component optimization runs conducted for roads, sewer, and water that used the same methodology for calculating component score but were run independently of the other right of way components. Overall the holistic objective function succeeded in providing superior plans in terms of minimizing the component score of each component while also saving money. This was achieved despite searching a much larger search space plagued by a greater possibility of achieving an infeasible answer. Results showing the average percent better in terms of component score over the twenty runs for the holistic function and the money saved can be seen in Table 1.

Table 1. Holistic Model's Ability to Outperform the Individual Models

Criteria	Low Budget	Medium Budget	High Budget
Percent Better for the Holistic Mean Component Score from 20 Optimization Runs:	3.1%	6.8%	8.7%
Percent Better Best Component Score:	2.3%	10.2%	9.8%
Average Percent of Budget Saved via Holistic Method:	8.6%	10.4%	10.8%

USING HOLISTIC RESULTS TO OVERCOME BUREAUCRATIC BARRIERS

While achieving a paradigm shift towards holistic right of way infrastructure planning faces many challenges, there are two primary bureaucratic barriers that prevent holistic planning from becoming a reality. The first bureaucratic boundary is the general nature of municipalities that are operated within democratic governments. City council members, assemblymen, and various other elected representatives lobby for right of way maintenance, rehabilitation, and renewal dollars to be spent in the areas they represent. This allows them to provide their constituency with tangible evidence of their efforts to improve the infrastructure in the area they represent. This operational structure can lead

to inefficient spending of taxpayer dollars where certain areas receive more funding based on the ability of their representatives to solicit funds.

The second bureaucratic boundary that prevents a paradigm shift towards holistic planning for right of way infrastructure maintenance, rehabilitation, and renewal stems from departmental priorities and specialization. As was noted by Antonoff et al. (2009) opportunities for city-wide benefits are not realized because departmental priorities supplant broader priorities. The results of departmental priorities supplanting broader priorities is similar to the results generated when city officials direct spending to occur in the areas that they represent. In the case of departmental priorities supplanting broader priorities, department heads direct spending to occur in areas where the dollars will have the most visible impact; thus, giving the outward appearance of a job well done. The potential for neglect in less visible areas is prevalent under this system and as was noted previously the consequences associated with operating in the traditional paradigm is that transportation projects miss opportunities to provide access to utilities and utility projects move on their own timeline without coordination across utilities (Antonoff et al. 2009).

Overcoming these two barriers and a achieving a paradigm shift will require the use of dominant information. As noted by Kashiwagi et al. (2009) and Hamel (2007), without dominant performance information perceptions and decision-making by industry experts will maintain the status quo. In the case of right of way infrastructure management there are several pieces of dominant information that need to be used by managers in order to generate the support required to achieve the paradigm shift towards holistic right of way infrastructure management. Such pieces of dominant information include:

- The status quo method of managing right of way infrastructure networks from within silos has lead to a $658.1 billion shortfall in planned spending that is considered necessary to operate the nations road, sewer, and water networks at satisfactory levels.

- When applied to a right of way network in Tuscon, Arizona, the holistic maintenance, rehabilitation, and renewal planning model that is presented in this research generated a minimum average budget savings of 8.6 percent over a five year planning horizon by synchronizing collocated projects from different infrastructure components in order to achieve economies of scale.

o When applied to the $658.1 billion shortfall that 8.6 percent savings would eliminate $56.6 billion dollars of the deficit.

- The holistic approach described above can be applied to any network without the need for municipalities to abandon their current condition and criticality rating programs. The methodology was designed to assist in decision making, not to redefine condition rating procedures.

Dominant Information to Overcome Boundary One

The dominant information generated in the form of the superior maintenance, rehabilitation, and renewal plans that are generated by the holistic methodology described in this research needs to be used by municipal managers to overcome the inefficient

practice of city representatives demanding that infrastructure funds be spent in their area. The fact that the maintenance, rehabilitation, and renewal plans that are generated by the holistic methodology are generated using modern evolutionary algorithms that consider millions of generations of possible answers before settling on an optimal or near optimal plan, can be used to assuage any city representative demanding that money be spent in the area that they represent. The data generated by the holistic methodology can be used to show the city representatives the holistic plan creates a plan that is the best for the city as a whole and should not be ignored in order to cater to the emotional appeal of an individual representing a constituency. It also serves to hold them accountable for their decisions should they choose to ignore the data generated by the holistic methodology.

Additionally, the savings that are generated by the holistic methodology can be shown to elected representatives in order to show the amount of funds that are being saved and reinvested for use on additional projects. With the project synchronizations that are identified by the holistic methodology, those savings would not be realized and the additional projects undertaken using those savings would not be possible.

Dominant Information to Overcome Boundary Two

Municipal managers can also utilize the dominant information identified above and that is generated by the holistic methodology in order to overcome the boundary that is put into place by the current paradigm where departments operate in silos. The holistic plans outperform plans generated by individual planning methodologies in terms of cost and the number of project that are able to be undertaken. When presented with this information, departmental managers will be hard pressed to continue to operate in their silos.

One area of difficulty that departmental managers that are responsible for a single infrastructure component might have is that the holistic methodology requires some give and take by networks that are being considered in the methodology. An example of this might be the water department having to push back a water project a year or two in order for a collocated road project to have the necessary funding to be undertaken. While the water department might have the funds ready to undertake their project, by waiting for the corresponding road project, a 20 percent saving can be achieved through combined overhead and the road project providing access to the subsurface waterline. Departments will have to be able to shift their thinking towards long term city objectives rather than short term departmental goals.

Departmental managers that fear and increase in workload or the stretching of resources in order to utilize the holistic method should also be informed that it requires no changes to their current data gathering, condition rating, and criticality rating procedures. After importing the data associated with a municipalities GIS, the decision making engine can run in the background with minimal human interfacing. During the times when projects

need to be identified the output from the holistic methodology would be consulted and the projects that it identifies can be put into motion.

CONCLUSIONS

A holistic methodology was created for the planning of right of way infrastructure maintenance, rehabilitation, and renewal of right of way infrastructure assets. The methodology considers all three networks simultaneously in order to synchronize projects for collocated segments from different infrastructure components in order to generate savings in the form of shared overhead and road projects providing open space to subsurface utilities. The methodology was designed to be easily implementable without requiring municipalities to dedicate resources to adapting their condition and criticality schemes that are already in place. The results of the application of the methodology to a right of way infrastructure network in Tucson, Arizona showed a minimum savings of 8.6 percent of the maintenance, rehabilitation, and renewal budgets for water, sewer, and roads during the five year planning horizon. With these savings additional projects were able to be undertaken and the overall condition of the three infrastructure components were improved when compared to the traditional paradigm where departments operate in silos. The information generated by the holistic methodology should be used by municipal managers to ensure cooperative planning across departments and to break departmental employees out of their silos. Additionally, the information associated with plans generated using the holistic methodology should be used to by municipal managers to overcome the inefficient practice of city representatives demanding that infrastructure funds be spent in their area. The fact that the maintenance, rehabilitation, and renewal plans that are generated by the holistic methodology are generated using modern evolutionary algorithms that consider millions of generations of possible answers before settling on an optimal or near optimal plan, can be used to assuage any city representative demanding that money be spent in the area that they represent.

ABSTRACT

Government organizations have seen the amount of protests on public procurements increase. Protests are a problem because they require additional resources and time to procure public services. The Industry Structure (IS) theory identifies that the problem is due to buyer decision making and control. The State of Oklahoma in partnership with Arizona State University in an effort to resolve their protest issues, tested a procurement process that forces the decision making and control onto the supplier. The results of the test cases are shown in this paper. The results show, as clients minimize decision making and force suppliers to be responsible for showing their expertise, protests are minimized, cost decreases, and performance increases.

Keywords: best value, buyer, PIPS, procurement, protests, supplier

INTRODUCTION

Government organizations for the last decade have had to deal with suppliers protesting their purchasing processes and awards. This is an issue that government organizations have seen continually grow. The State of Washington identified that they receive around twenty protests a year, and they have seen that grow from 2003 (Zeigler, 2006). The University of Maryland (2009) did a bid-protest study on the Department of Defense (DoD), identifying that the bid-protests have increased 40% from 2001-2008 (Gansler, Lucyshyn, and Arendt, 2009). The Government Accountability Office (GAO) released their fiscal year 2011 statistics on protests and found the following (GAO, 2012):

1. GAO received 2,353 protests in 2011. This increases by 2% from 2010 and over 40% since 2007.
2. They sustained 67 protests.
3. Hearings were conducted for 8% of the cases.

[1] Jacob.Kashiwagi@asu.edu
[2]John_Morrison@dcs.state.ok.us

The GAO stats also show that in 42% of the cases, the protestor received some form of relief from the government. One of the major problems with protests is that they can be time consuming and costly, taking resources away from needed improvements and services. Some of the main reasons for protests were are as follows (GAO, 2012):

1. Failure to follow procurement process correctly.
2. Improper evaluation technique.
3. Incorrectly evaluating a supplier's proposal.

State of Oklahoma Protest Problems

In 2008, the State of Oklahoma purchasing department approached, the Performance Based Studies Research Group (PBSRG), based out of Arizona State University, with the problem of their purchasing process and awards being protested by suppliers (OCDPS, 2009). The State felt that due to their procurement process, they were not able to justify their selection decisions, which allowed suppliers to continually protest their awards. This caused the following problems for the State:

1. The time to procure services was lengthened.
2. The cost for suppliers to bid on their projects would increase.
3. The cost of the State to procure services increased.
4. Prevented the State, in some instances, from obtaining the highest performing and lowest costing services.

Some of the problems they were experiencing with their current procurement process were:

1. Justifying the ratings given to supplier bid proposals.
2. Justifying pricing evaluation.
3. The complexity of the process caused difficulty for both the purchasing agent and the suppliers participating on a solicitation.
4. Proving selected suppliers meet mandatory requirements.
5. Justifying disqualification of suppliers due to not meeting requirements.

The State was in search for a procurement process that not only prevented protests from occurring, but also was still able to identify high performing suppliers from both price and other criteria.

Industry Structure Model

To identify a solution for the State of Oklahoma purchasing department, PBSRG used the Industry Structure model developed by Professor Kashiwagi (1991). The Industry Structure (IS) model was originally developed for the construction industry, but has now been applied to all services industries (Kashiwagi, 2012). Figure 1 is the industry structure (IS) model. The Industry Structure assumes the following:

1. The client is not the expert and has less experience in delivering services than suppliers.

2. The supplier is the expert on delivering services.
3. When the supplier controls and manages a project, the efficiency on the project improves due to the supplier's expertise.

The IS concept also identifies the price-based and the value-based environments. The major difference between the two quadrants is that in the price-based quadrant, the buyer or client is the one controlling and managing the project. Characteristics that accompany the client controlling and managing the project in the purchasing of a service include:

1. Client identifying what the requirements of the project are.
2. Client being responsible to identify the difference between suppliers in the evaluation process.
3. Client being responsible to validate that the suppliers have met the requirements on the project.
4. Client is responsible to ensure project performance.

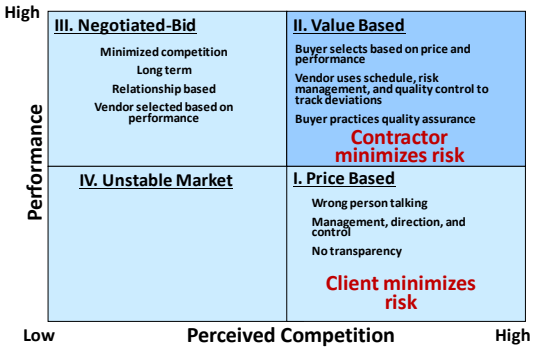

Figure 1: industry Structure (Kashiwagi, 2012)

However, since the client is not the expert, they are not capable of performing the actions of managing and controlling a project. Therefore, the performance and efficiency on a project decreases. When the client tries to take control of the project the following occurs:

1. More decisions are made.
2. The situation is more complex.
3. Risk and errors increase.
4. Efficiency decreases.

The IS identifies that in the value-based quadrant, performance increases due to allowing the expert to be in control of a project. The expert supplier is, therefore, required to do the following when participating in the procurement of a service:

1. Must compete to identify themselves as the best value.

 ISBN: 978-1-84219-840-7 .

2. Identify what the requirements of the service should be.
3. Show validation that they meet the requirements of the service.
4. Identify what differentiates themselves from other suppliers.

When a supplier is in control of a service the following occurs:

1. The supplier is responsible for decisions.
2. The situation becomes clear and transparent.
3. Risk and errors decrease.
4. Efficiency increases.
5. The process becomes simple and easy to understand.

The IS identifies that currently protests are a problem for purchasers, because the wrong person is in control of the service. The authors propose that as buyers transfer control and accountability to expert suppliers, protests will decrease and become easier to handle due to the following:

1. The selection process will be less complex and easier to perform.
2. Risk and Errors in the selection process will be minimized.
3. Transparency of the process and decisions will be easier to justify.
4. Evaluations will be more objective and less subjective.

PIPS Process

The only procurement system the researcher could find that allowed the buyer to let the expert suppliers take control of the service was the Performance Information Procurement System (PIPS). The PIPS has three phases (Figure 1). The phases are selection, clarification of proposal, and the award of contract and risk mitigation. The selection phase has multiple competing offers. The clarification phase handles one supplier at a time, starting with the vendor identified as the highest performing. Suppliers are assumed to be experts and are at risk until they are identified and their offer is accepted by the buyer. Suppliers can be eliminated before the selection starts due to being non-responsive to the process requirements or at the short listing where due to multiple suppliers proposing, interviewing all the suppliers may not be logical, especially if some are non-competitive after the first few submittals. Suppliers can also be eliminated if they are not in the competitive range (too high a price or too low a price), or if a supplier's submittal contains inaccurate material. If buyer has to make a decision, the supplier is probably not the best value supplier.

Figure 2: Performance Information Procurement System (PIPS) Phases (Kashiwagi, 2012; Kashiwagi, et. al., 2009)

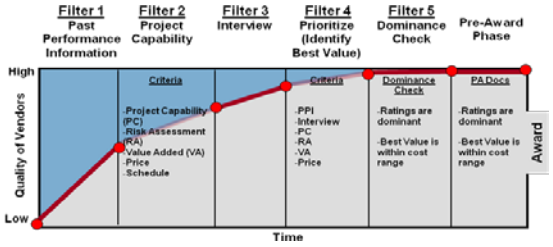

Figure 3: Selection Phase Filters (Kashiwagi, 2012)

The selection phase criteria are (weights in parenthesis showing potential importance):

1. Past performance information that is required on the supplier and the individual (10).
2. Project capability (20).
3. Risk assessment (15).
4. Value added (10).
5. Price (20).
6. Interview (25).

The price is already controlled by the budget and the competition. If the best value is over 5% over the next best value, it is deleted unless there is dominant information to show otherwise. The percentage is predetermined by the buyer. If the best value is lower than 10% below the average price, the supplier can be eliminated unless the supplier has submitted dominant information in the proposal. Dominant information is when the information is simple, easy to understand, and motivates the buyer to act without extra justification. The Selection Phase filters (Figure 2) work in unison to mitigate the chance of a non-performer getting the award or a protest occurring. The key components of the best value approach are:

1. Project capability, risk assessment, and value added submittals are short (2 pages maximum) and contain claims and verifiable measurements to support the claims.
2. The rating system is "10", "5", and "1." If a decision has to be made, the rating is a "5." If the claim is high performance, and the verifiable performance metrics are submitted, the rating is a "10."
3. The supplier's key personnel must go through an interview and identify what they are going to do before they do it, how it is different and how they will

mitigate risk that they do not control. The supplier's project manager's answers will be concise, short and clear.

4. The environment is transparent. Decisions will not be made. Time will not be spent to make decisions. If dominant information is not provided that identifies a vendor as a performer, the selection committee rating will be a "5" signifying the selection committee does not know if they are a performer. The predominant rating given is a "5". Instead of identifying a vendor as a non-performer, the system identifies the dominant performer who is supported by dominant information. [Simple, easy to observe information that leads to consensus and needs no further justification.) After the selection phase, the clarification phase will ensure the supplier can perform.

CLARIFICATION PHASE

The highest prioritized best value that has made it through the selection phase and dominance check will enter the clarification phase. The supplier will clarify their proposal. The rationale is that only the supplier who is going to do the job should be required to do detail planning. The supplier will clarify their proposal with more details. The clarification will include (Kashiwagi, 2012):

1. What is in and what is out of the scope.
2. A detailed schedule that will include activities where there is not enough information or elements that are outside the control of the supplier.
3. How the risk will be mitigated.
4. How the supplier's performance of risk mitigation will be tracked.
5. A weekly risk report that will include a milestone schedule, documentation of all project deviations, the source of the deviations, and the solutions, a tracking of the cost deviations and a risk management plan to mitigate risk.
6. Answer any technical questions the buyer's subject matter experts (SME) may have.

The supplier will then put together the above information, the client's requirements, the client's legal contract requirements and any other documentation, and submit it as the supplier's offer. Once the buyer accepts the offer, the supplier must perform according to their contract, reporting weekly to the buyer. The supplier is responsible for quality control and risk management, and the client is responsible for quality assurance (ensuring that the supplier has their risk management program and the project requirements are being met.) The Best Value PIPS Environment should place the client in a very non-confrontational position in selection processes due to:

1. Minimized decision making.
2. Suppliers propose and prove that they are the best value based on dominance.
3. Finding best value for the lowest cost.
4. Use of dominance required for greater value.
5. Transparency.
6. Documentation of performance information.
7. Protesters are left out on the limb. They must prove poor decision making or bias.

Hypothesis
Following the Industry Structure theory, it was proposed that a process which gives control to the right party, minimizes buyer decision making, and uses transparency will minimize protests and allow the public to defend them better.

Methodology
To test the hypothesis it was proposed that the State of Oklahoma test the PIPS on three projects that have had a history with protests, then to document the results to see if the process helps minimize the State's problems with protests.

State of Oklahoma Protest Projects
The State of Oklahoma identified the following projects to run with the PIPS process (Kashiwagi, 2011):

1. Light Bulb and Fixture Contract
2. Emergency Hazardous Waste Removal
3. Juvenile Services and Facility

Light Bulb and Fixture Contract
The procurement of the State of Oklahoma Light Bulb and Fixture contract had a long history of protests. This was the first procurement they decided to test the PIPS process on. The scope of work for this contract was supplying all light bulbs and lighting fixtures for the State. It was estimated at $3M over the course of three years. After the selection process was performed, one of the suppliers was selected for the service. The top 3 suppliers' final scoring are shown in Figure 4.

Top Three Suppliers

No	Summary Criteria	Unit	Vendor 1	Vendor 2	Vendor 3
1	Cost	#	$117,440.47	$104,017.99	$108,295.70
2	RAVA Plan	(1-10)	6.10	8.2	6.3
3	PPI Survey	(1-10)	9.98	9.896	9.785
4	PPI #/Clients	#	10.00	10	8
5	Interview	(1-10)	7.5	5.25	8

Normalization

No	Summary Criteria	Unit	Vendor 1	Vendor 2	Vendor 3
1	Cost	#	0.89	1.00	0.96
2	RAVA Plan	(1-10)	0.69	0.92	0.71
3	PPI Survey	(1-10)	1.00	0.99	0.98
4	PPI #/Clients	#	1.00	1.00	0.80
5	Interview	(1-10)	0.94	0.66	1.00

Final Scoring

No	Summary Criteria	Unit	Vendor 1	Vendor 2	Vendor 3
1	Cost	#	39.86	45.00	43.22
2	RAVA Plan	(1-10)	10.28	13.82	10.62
3	PPI Survey	(1-10)	10.00	9.92	9.80
4	PPI #/Clients	#	5.00	5.00	4.00
5	Interview	(1-10)	23.4375	16.40625	25
			88.58	90.14	92.65

Awarded Supplier

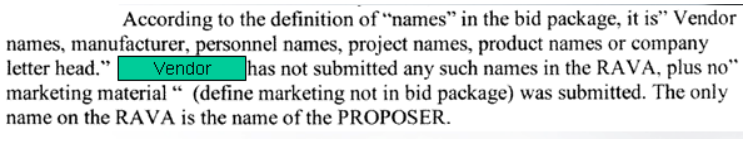
Figure 4: Top Three Suppliers

Selection justification for Supplier 3 was as follows:

- Supplier 2 did not complete pricing sheet
- Supplier 3 was backed by 2 out of 3 of the major lighting manufacturers.

- Supplier 3 offered to provide a State training program for all state end users.
- Supplier 3 Offered audits of facilities for analysis to improve energy efficiencies and lighting products.
- Supplier 3 had the highest interview rating.
- Supplier 3 would track and document all transactions and provide performance measurements throughout the length of the contract.

After the selection was announced two suppliers protested. Supplier 4 had a history of protesting this contract, and had always been successful with acquiring a piece of the service. They were kicked out of the procurement process due to placing their name on the submittal. Supplier 4 tried to protest for the reason identified in Figure 4.



According to the definition of "names" in the bid package, it is" Vendor names, manufacturer, personnel names, project names, product names or company letter head." Vendor has not submitted any such names in the RAVA, plus no" marketing material " (define marketing not in bid package) was submitted. The only name on the RAVA is the name of the PROPOSER.

Figure 5: Supplier 4 Protest Reason

Their protest was denied due to the following reasons:

- 4 out of 6 suppliers understood the rules and had no complaints.
- 1 supplier apologized for putting their name on the submittal.
- All suppliers were allowed to ask questions of clarification, Supplier 4 did not ask a question on the RAVA plan names.
- "Proposer" and "Vendor" used interchangeably throughout RFP.

After the explanation Supplier 4 decided not to pursue their protest. It was the first time Supplier 4 was not able to successfully protest the light bulb award. Supplier 2 also threatened to protest the bid. Their claims were as follows: Penalized due to not having a manufacturer representative at interviews and a better interview would have won them the contract. The protest was denied for the following reasons: suppliers all agreed that manufacturer representative should be optional at pre-bid meeting, addendum sent out from the state on the issue, and interview dates were posted for over 3 weeks. After the explanation Supplier 2 also decided not to pursue the protest. The selected expert supplier ended up giving the State a very high level of service. During the first quarter of the contract the supplier, through their documentation of services provided, found that they could offer the State greater savings on certain items due to the amount of the item the State was purchasing. The supplier has given the State over $133K worth of discounts, which has saved the State over 60% on their purchases, from the supplier's original pricing.

This project showed the State of Oklahoma that protests can be minimized by a process that: tells the suppliers upfront what is required, allows the suppliers to have

input in the process, and gives the suppliers a simple explanation to any questions they have concerning the fairness of the process.

Emergency Hazardous Material Removal

The State was looking for multiple suppliers to provide emergency response for clean-up and removal of hazardous waste. Historically there were two main suppliers for this service and if either supplier did not get awarded the contract they would protest the award. After going through the selection process, Supplier A and F were selected for the award, neither one were the main suppliers that had received the awards for the previous solicitations. One of the larger incumbent suppliers tried to protest the process due to the following reasons: having the lowest cost, lack of credibility of other firms, and faulty evaluation of bids. The result was as follows:

1. Supplier D protest to purchasing director denied.
2. Supplier D appeals to administrative law judge.
3. Supplier D did not show up for the court hearing.
4. Protest Denied.

Due to the simplicity of the process and the thorough documentation kept by the process, the contracting officer was able to quickly prepare the State's defence with minimal legal aid. Both the lawyer and the contracting officer were disappointed that the supplier did not show up, due the strength of their case. The performance of the selected suppliers turned out to be very high performing. Although the award suppliers were smaller than the other companies, they turned out to be just as reliable and capable of delivering high quality services as the larger suppliers.

Having a simple transparent process was able to not only to defend against a protest, but also helped to provide a system that allowed all companies to have a fair opportunity of being awarded State contracts.

Juvenile Services and Construction

The last project that was selected by the State of Oklahoma was services for running a Juvenile Detention Center and the building of a new Juvenile Facility. This project was at risk for many protests due to the following (PBSRG, 2012):

1. Many political entities would be involved in the process.
2. Both private and local governments would be involved in trying to bid for the project.
3. The selection committee involved many individuals that had political connections.
4. The State did not know a way to minimize subjectivity in the evaluation of the suppliers.

The PIPS process was able to minimize many of their concerns by the following:

1. All supplier evaluations were performed "blind"; the selection committee did not know who submitted what proposal.
2. The interview ratings followed the PIPS rating scheme. Meaning that all suppliers received a rating of "5" (which meant the committee member did not know how "good" or "bad" the supplier was), unless they provided dominant information justifying a higher rating. This was enforced by the purchasing officer.
3. The entire process was documented and simple and easy to confirm. .
4. The State identified their need but not how to meet the need. They asked the suppliers to identify and propose their solution to the identified need of the State.
5. The State did not make any decisions. If the information was not "dominant" the selection was made based on the best value for the lowest price.

After the State selected a supplier to provide the service and construction, they received only 1 protest. That protest was then followed by an accusation that a lobbyist of the identified best value was having an affair with a State Senator, who had colluded to help the selected supplier get the contract. The protest process was then escalated to a review by the State Senate and then eventually by the Attorney General. The State was able to quickly respond with the documentation and information on the process. After reviewing the submitted information, the Attorney General sent out an official statement saying (Kashiwagi, 2012):

"*In conclusion, there does not appear to be any evidence that DCS (State Purchasing) procedures were compromised or that any undue influence was exercised during the RFP process at issue. Based on my understanding of the PIPS process as outlined above, it would be very difficult for someone to manipulate the blind evaluation procedures that are in place. In this instance, the winning RFP was judged to be superior by a fairly wide margin. This judgment was shared across the board by all evaluators. The existence of an affair between a Senator and an interested lobbyist is irrelevant due to the controls present in the PIPS system. There was no evidence that the process was compromised or undue influence was exerted to justify further investigation of this matter as a potential criminal violation."*

After 2 months the protest was denied. Unfortunately, due to more political activities, the project was not funded. However, the process clearly showed how the procurement office could easily navigate through a very “protestable” environment with the least amount of effort.

CONCLUSION

A process was created that minimized protests by changing the control of a service to the right party, minimizing decision making, and creating transparency, minimizing protests and helping the State of Oklahoma government purchasing departments become better equipped to defend against protests. The State of Oklahoma ran three projects testing the protest minimizing PIPS, a process that allows the buyer to switch accountability and control to the “expert” suppliers. The results of the tests found the following:

1. The process minimized protests from occurring.
2. The process helped the State to defend against protests that do occur.
3. The process helped resolve protests easily and quickly.
4. The process helped the State to award and defend suppliers that could deliver the best value to the State.

By transferring control to the right party, it not only decreases the effort on government purchasing, but allows for a more efficient and value driven process to occur.

ABSTRACT

Today, uncertainty represents a threat to any business and/or project; however, it can be handled with risk management to reduce its effects. Many industries have taken and driven an approach to risk management in their companies. Worldwide, the mining industry has had a sustained increase in investment, operational expenses and in outsourcing contracts, and has made procurement and contract management, an opportunity to obtain savings and developing competitive advantages, particularly when procuring construction services. This work presents the results of a research effort that has established key risk management factors in the procurement and contract management process, through a review of existing risk management maturity models, employee opinion, and a literature review. It describes characteristics of the identified factors, along with a description of its segmented features on a scale of 5 levels. It was concluded that the most leveraging factors for proper risk management in procurement and contract management are: organizational culture, implementation of risk management and process structure. The ultimate goal of this work is to present the key risk management factors to highlight them and raise awareness about the importance of managing risks, so that benefits can be received by the company, its projects, and its stakeholders.

Keywords: awareness, key factors, procurement and contract management, risk management.

INTRODUCTION

We are currently facing an increasingly more uncertain world, which represents a clear threat for businesses but also a chance to take advantage in generating even new opportunities (Hillson, 2011). The actual situation in the mining industry shows a sustained increase in operational expenses and the procurement of outsourced services (Cochilco, 2009; Consejo Minero, 2010). Handling the uncertainty, an effective procurement and contract management (PCM) become a key factor to obtain savings and to become developing competitive advantages (PriceWaterHouse Coopers and Memba, 2003). However, a systematic vision of Risk Management (RM) in PCM has

[1] rmhoward@uc.cl
[2] aserpell@ing.puc.cl

not been established. Given this scenario, organizations wishing to implement a formal approach to RM or improve existing approach, need a framework to contrast their current practices (Hillson, 1997).

THEORETICAL BACKGROUND

Clearly, there is uncertainty in everyday life, organizations and projects (Olsson, 2007), representing a clear threat to the business, but also in itself is a significant opportunity that must be taken to improve (Hillson, 2011). Its definition has been taken from different points of view, but Hillson's (2004) connects it to a risk as follows: "The risk is the uncertainty measured, and uncertainty is a risk that cannot be measured."

Risk is a multifaceted concept (Wang et al, 2004), which is defined as the probability of a damaging event occurring within a project, affecting its objectives (Yu, 2002; Baloi and Price, 2003) however, it not always associated with negative results. Risk may also represent opportunities, but the fact is that most of the risks usually have negative results that have led individuals to only consider the negative side (Baloi and Price, 2003, Hillson 2011).

Risk management today is an integral part of project management (Olsson, 2007), and was originated from the U.S. in the 1930s, associated to insure the businesses at an early stage (Zheng et al, 2009). This is a key process and most project managers know that risk management is essential for good project management (Baloi and Price, 2003; Perera and Holsomback, 2005).
Risk management is defined as the process to identify, access risk and to apply methods to reduce it to an acceptable extent (Tohidi, 2011). Overall, RM process includes the following main steps (1) Risk planning, (2) Risk identification, (3) Risk assessment (qualitative and quantitative), (4) Risk analysis, (5) Risk response, (6) Risk monitoring, and (7) Recording of the RM process (ISO 31.000, 2009; Baloi and Price, 2003; and others).

On the other hand, from the point of view of the research procurement and contract management that has been analyzed due to its relevance to the commercial sector as an essential part of the supply chain (Pollice and Fleury, 2010). Although in the contracting corporate world it is not usually a major activity of an organization, it is a distinctive support function (Plomp and Batenburg, 2009). Organizations with established processes and mature PCM are able to generate millions of dollars in additional savings and have a clear competitive advantage over their competitors (Rendon, 2007).

The maturity models can provide a framework, which serves to carry out a comparative assessment (Demir and Kocabas 2010), lead the organization strategically, and link it to its continuous improvement (Brookes and Clark, 2009). While there are maturity models for RM (Jia et al., 2011), they are not fully described and there is not a complete developed model associated with the process of PCM.

RESEARCH PROBLEM

This research is intended to identify and describe the key factors for assessing RM in PCM in mining companies. These factors will be set through a literature review and a compilation of background information. This is provided by employees associated with the PCM process within a company belonging to the industry. Thus, it aims: (1) to raise awareness regarding these factors in order to develop the RM in the PCM, (2)

to find leverage factors for this process, and (3) to establish the basis for the development of an evaluation system and performance monitoring of RM in PCM (based upon maturity models). Given the above information and the context within which this process unfolds, a research question has been formulated as follows: What are the key factors and their importance for evaluating RM in PCM?
Then, the objective being pursued is to structure and describe the relevant factors for evaluating RM in PCM, providing an appropriate measurement range to develop a maturity model in the future.
This research, being based on insights and specific characteristics of the mining industry as well as important clients of construction companies and can also be a good reference for companies working in other areas.

RESEARCH METHODOLOGY

The methodology to carry out the research has been based on: (1) maturity models of RM that have been reported in the source of references, (2) papers and consulting results associated with both, the RM process and the PCM, and (3) results from information gathered within a mining company to put into context the factors according to the Chilean reality. In order to complement this information, an expert in RM in contracts has collaborated to the research with the purpose of having an expert view and validating the found factors. Already with the factors and their identified and described dimensions, a scale of general measuring has been structured, providing the basis for developing a monitoring and evaluation system based on maturity models.
After the key RM factors were identified, their main characteristics and dimensions have been defined. With the purpose of: (1) knowing the opinion of those involved in the process of PCM and (2) find out about the degree to which the key RM factors reflect the reality of the process and which are the leverage factors of RM in PCM, a questionnaire has been applied to mining companies' personnel. Figure 1 outlines the research methodology just described and it links each stage with the main results.

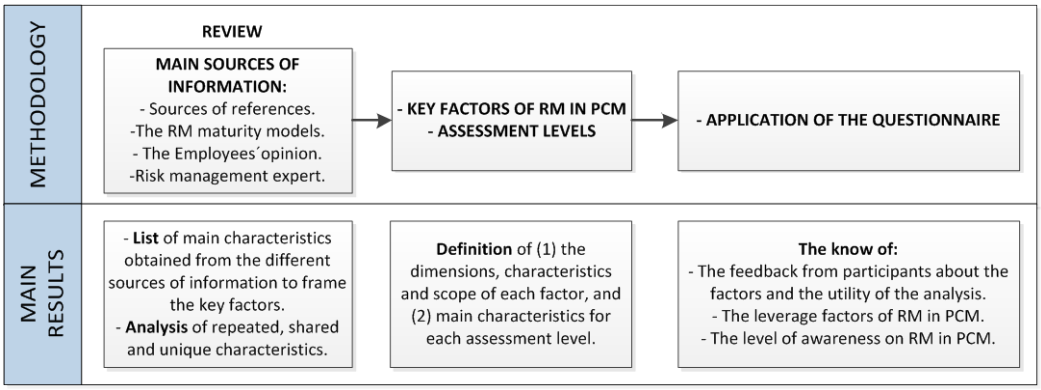

Figure 1. Summary of the research methodology.

MAIN RESULTS

Key factors:

The key factors of RM in PCM have been structured through a comprehensive analysis of four main sources. For each of the four main sources were classified the different key factors and their dimensions. Later another analysis was carried out for identifying the characteristics that were repeated, the ones that complemented each other, and the ones that were absolutely new. Finally, both analyses were classified

according to common classifications in order to obtain the main factors. This process was developed as already described in Figure 1.
The scope and characteristics of each factor are defined by each one's dimensions, as described in Table 1.

Table 1. Dimensions and characteristics of each key RM factor, designed by the authors.

Factors	Dimension	Characteristics
Organizational culture	Awareness of risk management	- Employees and directors of the company are aware of RM and the risks involved in PCM.
	Support from upper management	- Upper management encourages and requires the application of PM in the PCM, strengthening a proactive RM
	Increase of update regarding risk management	- Communicate and disseminate news associated to impacts caused by the occurrence of any risk in the hierarchical structure of the organization.
	Recognition of benefits and importance of RM	- Valuation of benefits related to the implementation of RM and the importance of the implementation and results of RM in PCM.
	Willingness to make changes	- Capable leaders in order to encourage changes in the company. - Development of an optimistic view of changes. - Organizational openness in implementing organizational changes.
	The ability to collaborate and communicate	- Communication, collaboration and synergy created within and between sectors such as interaction between sectors from different areas within the company.
Process structure	Formality of the process	- Existence of a formal process of RM in PCM. - Degree alignment of such processes to the type project and integration into the company.
	Documentation of the process and information availability	- Documentation of RM in PCM. - Information of RM in PCM stored and available to support decision making and process improvement.
	Motivation for the implementation	- Reason why RM has been implemented in PCM (internal motivation or imposed externally).
	Training and skills development	- Level of competencies and skills of personnel involved in RM in the PCM. - Knowledge frequently updated and refined.
	Expertise (expert knowledge)	- Participation and involvement of experts in RM in PCM process.
	Involvement of key stakeholders	- Level at which key stakeholders participate and get involved into the process of RM in PCM.
Development and experience in risk management	Performance evaluation of risk management	- Assessment of RM in order to monitor, learn lessons from the process and seek continuous improvement.
	Employees experience	- Opportunity for experts and others involved in RM to implement and carry out the PCM process. - Previous experiences of those involved in RM.
	Distribution and knowledge development	- How the RM in PCM has collected, stored, used and shared the knowledge within the organization. - Use of the knowledge to continuously improve / a support for decision-making.
Implementation of RM process	Implementation of risk management	- Continuous and systematic application of RM in PCM. - Number of projects implementing the RM in PCM.
	Resource allocation	- Availability and resource allocation for RM in PCM.
	Responsibilities	- Definition, allocation and acceptance for the responsibilities of involved in RM process in the PCM.
	Available technologies	- Availability, application and integration of technologies for the development of RM in PCM.
	Risk identification	- Comprehensive risk identification, using the organization's support, resources and available information.
	Risk analysis	- Qualitative and quantitative analyses of risks by using appropriate tools and techniques.
	Response to risks	- Selection of response strategies to follow according to the

Factors	Dimension	Characteristics
		previous experiences and points of view of the stakeholders.
	Monitoring	- Use of a monitoring and controlling system for risks. - Evaluation and feedback at the end of each project.

The table 1 shows the basis of present research and includes all the efforts of the review, analysis and structure of the collected information.

Analysis of the review

In the study of the different models certain similarities or shared approaches were identified, as well as complements and unique contributions. The most important aspects of this analysis are presented in Table 2.

Table 2. Main factors identified as "unique", "shared" and "complementary".

Unique	Level of training in basic skills associated with risk management of employees.
	Implementation and periodic training of basic competencies associated to risk management.
	Level in which is shared knowledge and skills associated to risk management.
	Measuring and comparing the performance of risk management.
	Recognizing the benefits/importance of risk management.
	Resistance to change/technology.
	Degree of involvement of stakeholders with the mission and objectives of the project.
	Collaboration/communication between teams.
	Level of availability of technology for the process.
Shared	Carrying out stages of risk management.
	Allocation of resources for risk management.
	Allocation, acceptance and compliance of responsibilities in risk management.
	Customer participation in risk management process.
	Degree to which are known and climbed to higher levels the "bad news" associated with risks.
	Collection, storage and use of available information.
	Support and priority of upper management.
	Carrying out proactive risk management.
	Channels for explicit communication regarding risks.
	Inclusion of risk management as integral part of project management.
	Degree of implementation of the process and risk management practices.
	Risk awareness.
Comple-mentary	Development of relationship with the external network (Sponsors, government, suppliers, etc.).
	Encourage and enhance relations within and outside the organization.
	Formality of the management system, especially risk management.
	Using the information of RM in decision-making.

This analysis has been essential to know the state of the art on the factors considered in the different sources of information and it has also shown a first view of the leverage factors for RM.

Assessment levels

Along the key factors, it has developed a general scale of evaluation based on the review and analysis of the source of references. Using these key factors the company can identify its current performance depending on the characteristics and conditions that it has presented in the assessment. Figure 2 describes these levels.

	LEVEL 1	LEVEL 2	LEVEL 3	LEVEL 4	LEVEL 5
Organizational culture	Null culture and organizational awareness of risk and RM in the PCM	Basic level in awareness of benefits of RM in the PCM	Support from upper management in key projects	Benefits under-stood at all levels of the organization	Proactive view of RM, search of continuous improvement
Process structure	RM process in the PCM, not formalized	Structure and organizational support emerging	There is a formal system of RM in the PCM	Activities of RM consider key stakeholders	Incorporation of RM in the PCM in the management of the company
Development and experience in RM	There is not any experience in RM in the PCM	The experience depends on the people involved	It is possible to face most known and predictable risks	Experts in the company. Lessons learned are documented	It is learned from experience. Process knowledge is managed
Implementation of RM process	RM process in the PCM is not carried out	Partial development of some stages within the RM process in PCM.	Implementation of an overall process of RM in the PCM	Implementation of a systematic process of RM. Is adapted on key projects.	RM policies and procedures. These characteristics are tailored to the project

Figure 2. General scale of main characteristics of each level, designed by the authors.

The key factors and the general scale of assessment are the basis for building a monitoring and assessing system of RM in the PCM. Thus, forming framework to compare the current practices of the company studied.

Employee opinion

Finally, a questionnaire has been applied to eleven people involved in the PCM process in a mining company. All the factors were presented with their dimensions and characteristics. Respondents were asked questions as shown in Figure 3.

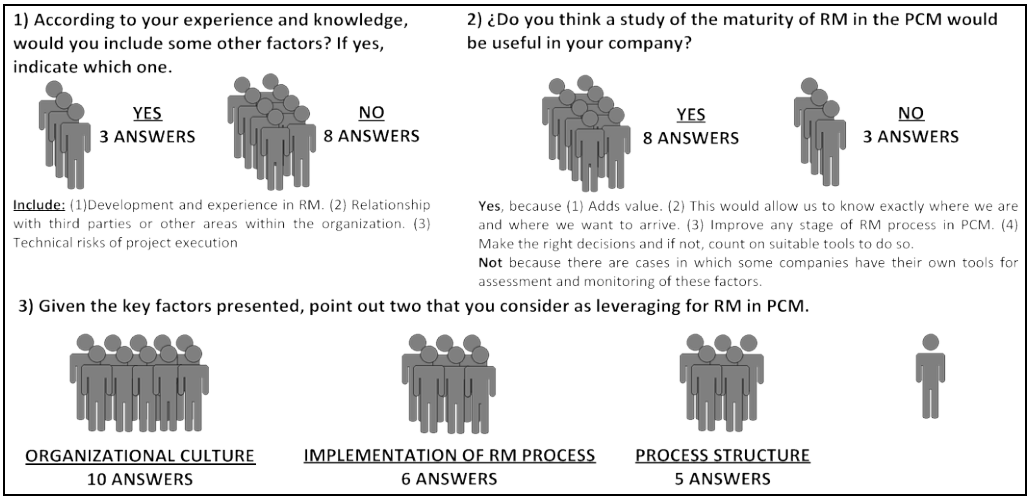

Figure 3. Responses to the questionnaire, designed by the authors, applied to the people involved in the PCM process.

The information collected from the responses to the questionnaire is very important because it allows us to know: (1) the feedback from participants about the key factors and the utility of this research, and (2) the leverage factor of RM in PCM.

DISCUSSION AND CONCLUSIONS

Key factors and leverage factors

It has been possible to establish a group of factors considering the fundamental aspects for the development of an effective RM in the PCM, achieving the integration and coordination of different business areas required for the development of this process, including characteristics of the organizational culture, organizational support for this process (training, use of technology, experts, resources, etc.), qualities and stages within the process of RM, and the involvement of stakeholders. In this manner,

we obtained: through the application of a questionnaire regarding what happens in practice, (1) a comparison of the key factors, dimensions and their characteristics. Then, based on the experience and knowledge of respondents, the factors were reaffirmed as key for RM process in the PCM, also, the comments left by the respondents were used to better define the characteristics and scope of dimensions of some factors; (2) an identification of leveraging factors of RM in the PCM by using the insights of people involved in the PCM process in mining companies. As key factor, the organizational culture stands out as the principal leveraging factor in RM (45.5% of respondents), followed by the implementation of the RM process (27.3% of respondents) and process structure (22.3% of respondents). Although these results are not useful to generalize since the survey is not a representative sample, we can conclude that it has validated the statement that the key factors obtained as a result of the research are not far from the actual situation of the companies.
Thus, we reaffirm the existence of four key factors for RM in the PCM, which correspond to (1) organizational culture, (2) structure of the process, (3) development and experience of RM and (4) implementation of RM process in the PCM.

Analysis of the existing risk maturity models
Regarding the study of maturity models applicable to RM, we can observe that there are different proposals for general maturity models for RM, but none focused exclusively on RM in the PCM. In many cases, these are briefly described and not clearly defined. Among them, there are the ones with certain similarities and common approaches, others that are complementary within themselves and also others with individual contributions. On a general basis it has been possible to find: (1) Models showing unique factors mainly cover dimensions regarding organizational culture, but none of the models is able to integrate the dimensions in order to fully structure this key factor. (2) In models that share elements, the ones related to the implementation of RM process are highlighted; this may occur because in the source of references there are a wide variety of manners to implement the RM, which in one way or another, converge into a general process. (3) Within the factors of the models that are complementary, the structure of the process becomes especially important regarding topics related to the development and incorporation of stakeholders in the RM process and the support to the decision making thanks to the information generated by the RM process. In addition, the key factors outlined in the previous analysis clearly match with the results regarding the leveraging factors of RM obtained by applying the questionnaire which reaffirms and connects the focus of source of references with the practice in the surveyed companies.

Awareness about risks and RM in PCM
The understanding regarding the awareness about risks and RM has been achieved, which allows identifying that the managers in the consulted companies are indeed aware. However, this remains only at this level and has not been transferred down to employees. The situation is most disturbing when knowing that one of the participants believes that neither employees nor managers are aware of neither risks nor RM in the PCM, showing a basic state of the RM in the PCM. This leads us to infer that there is not yet awareness regarding RM in the PCM, its benefits and the need of a structured system to address this area of management.
We believe that the diffusion of the knowledge of the identified factors will collaborate to strengthen the required awareness and will improve the performance of RM in the PCM in the companies. Overall, we observed that the interest and usefulness of an assessment model of RM in the PCM is high. Up to 72% of

respondents think it would be useful to apply a RM assessment system in the PCM, while the remaining percentage said it would not be useful, since in their companies has already been carried out an assessment. This leads to the second stage of this research, which seeks to develop a RM assessment and monitoring system for the PCM based on the identified key factors and their general levels of assessment, delivering a set of best practices to be implemented.

RISK MANAGEMENT STRUCTURE FOR VALUE-BASED COMMODITY CONTRACTS

ABSTRACT

The nature of a commodity implies that price is its primary differentiating factor. However, organizations increase their risk when they assume that the supply chain which delivers the goods is also a commodity; they select suppliers on the basis of lowest price. Organizations that award commodity contracts in this way may experience project delays, lack of effective communication, or customer dissatisfaction. The delivery of furniture services is often considered a commodity service. Arizona State University, on behalf of the Arizona Tri-University Furniture Consortium, identified concerns with their current furnishing services contract: misaligned customer expectations, minimal furniture supplier upfront involvement on large capital construction projects, and manufacturer design expertise not being utilized during project preplanning. The researchers developed and implemented a model that (1) provides a more efficient methodology for financial evaluation, (2) measures customer satisfaction, and (3) monitors project performance. The system has resulted in a 9.3 / 10 customer satisfaction rating (24 percent increase over the previous system), for over 1,100 furniture projects totaling $19.3M.

Keywords: best value model, commodity contracts, facilities management, furniture services industry, performance measurements

INTRODUCTION

The objective of this paper is to address the unrealized efficiencies buyer organizations can achieve by using a structured approach to identify and minimize risk. An area of significant potential improvement is in the selection and delivery of services that are perceived to be a commodity. Because commodities have minimal distinguishing characteristics, price is used as the deciding factor for which product or service to purchase (Rayburn, 2010; Reimann, Schilke, & Thomas, 2010; Rushkoff, 2005). When a buyer incorrectly assumes that price alone is a sufficient data point to make a decision, they expose their organization to risk that could have otherwise been minimized by considering additional factors besides cost alone (Gransberg, 1996; Kashiwagi & Savicky, 2003); we define this buyer behavior as exhibiting a "commodity mentality."

Problem

Large organizations inherently face increased difficulties in maintaining high levels of efficiency; that is, to create the greatest impact with the least amount of resources (Efficient, n.d.; Snyder & Morris, 1984).

The concept of organizational silos can be extended to the supply chain. Individual nodes along the supply chain that are operating in silos would not consider the profitability, efficiency, and interoperability of their value-adding functions as it relates to the rest of value chain (Blount, 2008; Katunzi, 2011; Milligan, 1999).

In an effort to meet their own performance goals, silos may use lower-cost suppliers, ignore the needs of the final end customer, and assign inadequate resources to new products and service design (Katunzi, 2010). Therefore, the nature of a large bureaucratic organization may foster "commodity mentalities" towards the entire supply chain that delivers goods and services which are (incorrectly) perceived to be "commodity."

Hypothesis and Paper Objectives

The purpose of this research was to test the applicability of a value-based risk management system in services which are typically viewed to have limited and quantifiable differences, with exception to price (commodities). The hypothesis was that implementing a best value business and leadership structure at the final buyer's position in the supply chain will increase upstream performance, and thereby result in increased performance at the buyer's site. The objective of this paper is to document the impact of a Best Value business leadership and risk management structure for a service that is typically perceived as a commodity (furnishing services).

Research Scope

In 1994, the Arizona Board of Regents (ABOR) mandated that the Arizona's three largest public universities (Arizona State University (ASU), Northern Arizona University (NAU), and the University of Arizona (UA)) abide by the Tri-University Furniture Contract (Tri-U Contract or Tri-U). The researchers utilized a best value selection and contract management processes called the Performance Information Procurement System (PIPS) (About PBSRG, 2012).

In July 2008, ASU's key staff approached the researchers and requested assistance to improve the delivery and performance of the Tri-U Contract. An interview with these individuals identified the following problems with the current Tri-U system:

- Customers do not always receive at the end of a project what was originally expected
- Lack of communication between the Capital Programs Management group, general contractors, furniture installation service providers, and University Business Services personnel
- Lack of performance measurements in terms of risk (on-time, on-budget)
- Lack of performance measurements in product deficiencies
- Manufacturer design expertise is not fully utilized during project pre-planning

Based on these problems, the researchers identified that the University may be using a commodity mentality towards the management of the Tri-U Furniture Contract. Upon further discussion with the ASU key staff, the researchers proposed that PIPS may have new application in the field of risk management of services typically perceived and managed as "commodity."

LITERATURE REVIEW

This brief literature review frames the concept of Performance Information (PI) and its use within organizations. Next, the review covers the role of PI in the processes that Facility Managers use to minimize risk. Finally, the researchers consider the special case of risk measurement in "commodity" services.

Use of Performance Information

Performance information, balanced scorecard results, and key performance indicators can be useful data to predict current or future performance of a company. A 1999 case study found that nonfinancial performance metrics in the airline industry (such as on-time flights or mishandled baggage) had a significant impact on future financial performance of the airline (Behn & Riley, 1999). Organizations may begin using non-financial metrics when their traditional processes or metrics no longer add meaningful value (Fakhri, Menacere, & Pegum, 2011). While the Facilities Management function is making progress, it still lacks adequate customer satisfaction information that is readily available (Tucker & Pitt, 2009).

Companies may also begin using data to increase performance in an effort to encourage personnel accountability. Hatry (2006) also identified that performance metrics help managers better allocate their limited resources. An effective metric simply identifies the risk an organization faces, which allows leaders to make adjustments to increase efficiency. Finally, Hatry (2006) identifies that performance measurement systems must produce accurate data from the beginning; not doing so may lead to decisions based on faulty information, and ultimately loss of confidence in the measurement system.

Facility Managers' Risk Management Process

Risk is defined as anything that affects time (schedule delays), cost, or customer satisfaction (Kashiwagi, 2002). In a broad business context, risk is anything that affects financial operations, and risk management is the process of preventing events from affecting such operations (Kraman & Hamm, 1999). While these definitions of risk are more measureable when applied to a project that has defined a cost and duration, understanding risk in a Facilities Management functions requires a different perspective.

The literature reveals a general three step approach to risk management. The first step is that FMs must measure their performance to get an accurate snapshot of reality. Tucker and Pitt (2009) suggest that it is especially important for FMs to measure performance in a variety of key areas that include both the financial and 'intangible'

aspects of their profession. Measuring different areas of performance helps organizations have a well-balanced approach to setting and monitoring their objectives.

The next step is to assess the probability of the risk occurring, and to develop plans that minimize the risk (Alexander, 1992). The key in minimizing the risk is to plan ahead before the risk actually occurs (Boehm, 1991). Facility Managers should also address any activity that could harm the financial viability of the organization (Barton & Hardigree, 1995). More recent literature suggests that FM departments should focus on the risks (or metrics) that have an impact on the value they add to the organization (Cotts 2010). Regardless of how a facilities manager views the type of risk to be managed, the common theme from the literature is to plan ahead before the situation arises.

An alternative approach to risk management, found as a component of the PIPS, is to transfer the risk and accountability to the expert (Sullivan & Guo, 2009). The philosophy can be used by Facility Managers to better manage their areas of responsibility. The PIPS process identifies that risk should be managed in the following manner (Kashiwagi, 2012a; Sullivan & Guo, 2009):

1. The expert should first identify what their overall plan is to complete the project.
2. They should then address anything that could stop them from being successful on the project, and provide a simple plan how they will minimize the potential risks.
3. Once the project or service has begun, the expert vendor should track any changes from their baseline expectation.

The actual process of transferring the risk to the expert occurs when vendor completes these steps, and the owner releases control and accountability to the vendor.

Risk Measurement of Commodity Services

A commodity, in its simplest definition is, “a mass-produced unspecialized product” (Commodity, n.d.). Generally, “commodification” refers to the practice of assigning a market value to a good or service that it did not previously have (Rushkoff, 2005). “Commoditization”, on the other hand, is the process where a good or service previously has distinguishing attributes and limited quantities, and becomes mass-produced and nearly identical, with price being the primary differentiating factor (Rayburn, 2010; Reimann, Schilke, & Thomas, 2010; Rushkoff, 2005).

Goldsby and Rao (2009) categorize the general types of risks that a supply chain may encounter:

1. Environmental factors – issues that affect the overall environment or situation that supply chain operates (politics, society, etc.).
2. Industry factors – issues within the market that the product is being sold.
3. Organizations factors – issues relating to the firm level, including behavior and research and development.

4. Problem-specific factors – issues relating to single issues that affect the entire supply chain.
5. Decisions-maker factors – issues relating to an executive, or steering committee, and the individual's or committee's level of expertise in making the decisions.

Production uncertainty is the only issue mentioned above relating specifically to the product delivered to the buyer. Therefore, the literature indicates that most supply chain risk is not related to the actual product being delivered, but risk is in the processes or systems that supply the good.

METHODOLOGY

The researcher divided the research methodology into two main phases. The first phase gathered background information and current conditions of the Tri-U Furniture Contract. The second phase used the results of phase one to develop a Request for Proposal (RFP), identify the potential best value vendors, and require the vendors to develop a detailed plan for their approach to manage and minimize contract deviations and risk.

Phase One

The primary objectives of phase one was to:

1. Meet with the industry to gauge interest in, and support for, a best value approach to furniture contract procurement and delivery
2. Identify the current conditions of the existing Tri-University Furniture Services environment

With permission from the University, the researcher coordinated and provided an optional best value information session to approximately 50 people from the furniture industry. The key factors discussed during the meeting were:

- The post-award purchasing structure needed to include a component that allowed buyers to make match-existing product purchases.
- Not all potential proposers have a State of Arizona furniture contract, and therefore, an evaluation criterion that considered list-price percentage discounts from the State contract could not be used.
- The proposers would like the ability to indicate if they were proposing on the budget or primary contract.
- ASU needed to provide historical purchasing levels for the different universities, and which contracts these purchases were made on.

Phase Two

Using the information gathered from Phase One, the researchers and the senior buyer from the ASU's Purchasing Department compiled the Request for Proposal (RFP). This RFP was the University's first furniture RFP that incorporated best value procurement methodologies, and as such, there were several differences from a traditional furnishing services RFP. In general, the Traditional RFP does not

specifically consider the proposers' ability to manage and minimize risk that would stop them from being successful on a project-by-project basis. The RFP established three different types of projects that the Universities have (Match-existing, Capital, Non-capital).

RISK MANAGEMENT STRUCTURE

Recall that the existing furniture purchasing process was totally void of performance monitoring and risk minimization protocols. The new best value approach contained tools to help monitor and minimize risk:

Table 3.4 – *Risk Management Tools*

Risk Management Tool	Description
Project Record List (PRL)	List of Small Projects that tracks cost, schedule, client contract information, client satisfaction, and any cost or schedule risks
Weekly Risk Report (WRR)	Used on a single Large Project and tracks detailed project information, cost, schedule, risks, and a Risk Management Plan

The updated purchasing process is described below:

- As in the previous RFP, the furniture purchasing process begins with a buyer need. Regardless of the Project Type, the Total Projected Cost is used to determine the Project Size.
- If the project is a Small Project, the Dealer first adds it to their Project Record List. They will then begin work on the project and document any risks that occur on their PRL. At the conclusion of the project, the Dealer is responsible for collecting a simple survey from the end client.
- If the project is a Large Project, the first, and most important step the Dealer takes is to modify their base RMP template (developed during the Pre-Award Phase), and ensure the client understands the dealer's Risk Management Plan. At the conclusion of this initial phase, the dealer holds a Summary Meeting with the client that recaps their RMP, the project schedule, and action items. As the reader may have noticed, this is in fact a smaller version of the Pre-Award Phase from the PIPS process. After the Summary meeting, the vendor moves forward as they normally would on a Small Project, and document risk and client concerns through the duration of the project. At the project conclusion, the dealer collects a more extensive, one-page client survey.
- All client satisfaction surveys are used in the vendor's Past Performance Information Database.

The structure is a system-wide mechanism that monitors each project, at each University, for each dealer. All project and risk data becomes part of the Best Value Information System, and serves the University system through the use of risk reporting tools, risk minimization, and performance monitoring and tracking.

DATA COLLECTION AND ANALYSIS

Client satisfaction increased by 24.3 percent under the best value system (as compared to the previous system). This increase in satisfaction was confirmed through rejecting a null hypothesis that there was no differential between the systems ($\alpha = 0.05$; H_0: $\mu_1 - \mu_2 = 0$; H_1: $\mu_1 - \mu_2 \neq 0$; p-value = 1.84E-21). The summary of client satisfaction is provided in Table X below.

Table 4.3 – *Summary of University Performance Differential*

No	Performance Criterion	Unit	Overall	ASU	NAU	UA
1	Baseline Overall Performance	1-10	7.02	7.23	6.35	7.43
2	Best Value Overall Performance	1-10	9.26	9.34	9.24	9.19
3	Baseline Satisfaction	%	77%	89%	50%	91%
4	Best Value Satisfaction	%	99%	100%	100%	98%

SUMMARY OF RESULTS AND CONCLUSIONS

The primary objective of this paper was to propose a more efficient approach to minimize and manage risk of "commodity" services. The best value Tri-University Risk Management Structure contains tools to help the suppliers manage the risk, and report this information back to the client. In short, the major conclusions of this research are:

- There is significant value in managing risk, even if the service is typically perceived as "commodity"
- A structured pre-planning methodology can be incorporated into a structure, which in turn helps all parties to coordinate
- Customer satisfaction under the best value has increased by 24.3 percent

ABSTRACT

Supply Chain Management (SCM) originated in the manufacturing industry and then in the construction industry in the mid 1990s. SCM is the management of the entire supply chain instead of individual parts or processes. Its aim is to deliver improved transparency and alignment of the industry's supply chain coordination and positively influence time, cost and quality aspects. Time and cost are important factors that developers and clients use to measure the success of projects. Prefabricated timber structural systems for multi-storey construction are a new innovation, as such time and cost aspects are critical to their commercial viability in the construction industry. They are an engineered-to-order (ETO) product and most SCM literature has neglected the needs of the ETO sector, in particular prefabricated timber structural systems. This paper aims to review the current state-of-art of SCM used in construction and discuss how it can best be adopted for prefabricated timber systems with a focus on improving time and cost. Semi-structured interviews were conducted with industry professionals across the supply chain of timber construction with the aim of identifying which areas of the supply chain have the greatest impact on time and cost. SCM strategies are then suggested to address these areas.

Keywords: Construction, Supply Chain Management, Engineered-to-order, Time and Cost

INTRODUCTION

Timber has great potential in multi-storey buildings due to its high strength to weight ratio, environmental attributes and ability to be prefabricated into lightweight modules. Cross Laminated Timber (CLT) is an example of this construction typology and has proved to be successful in Europe in multi-storey residential construction and is gaining interest throughout the rest of the world (Perkins & McCloskey 2010).

[2] keith.crews@uts.edu.au
[3] grace.ding@uts.edu.au

EXPAN is another prefabricated timber construction system that has been developed for non-residential building applications and is gaining momentum in the Australian and New Zealand (NZ) markets. There's a potential multi-million dollar market for prefabricated systems in multi-storey construction in Australia and NZ and the demand for such products is being driven by worldwide interest in sustainable building materials and modular construction. Prefabricated timber systems are more environmentally friendly than traditional forms of construction (Page 2006; Perez 2008 & John et al. 2011) though traditionally multi-storey commercial buildings have been constructed out of steel and concrete. This has been facilitated by designers and contractors familiarity with these materials, low on-site labour costs and ability of these systems to span the long distances required in commercial applications.

In this paper semi-structured interviews were conducted with a number of industry professionals throughout Australia, NZ and Europe and results showed that the environmental and aesthetic aspects of timber were considered as 'soft factors'. In order for new prefabricated timber structural systems to be truly commercially viable they need to be time and cost competitive with traditional forms of construction. Well-managed and efficient supply chains (SCs) between the firms producing these systems was highlighted as critical in achieving these cost and time benefits. Firms in all sectors are looking for ways to reduce costs, shorten product development times and manage risk. Firms in supply chains have a number of transactions that aim to add value upstream. Supply chain management (SCM) seeks to reduce the costs, risk and lead times of these transactions that result in increased value to the end customer. This paper looks into the current-state-of art of SCM in construction with a focus on ETO prefabricated timber systems, which have been neglected to date in literature. The business models of a number of firms delivering prefabricated systems are outlined and a comparison is conducted between these firms operating in Europe, Australia and NZ. This paper also provides SCM strategies for firms in Australia and NZ to assist in achieving a more cost and time effective procurement of these systems into the non-residential construction market.

Supply chains in Construction

An SC is defined as 'a network of organisations that are involved, through upstream and downstream linkages, in the different processes and activities that produce value in the form of products and services' (Christopher 1998 pg. 15). Until the 1980s procurement in the construction industry was based on transactions between one buyer and one seller. These transactions were used to meet specific project needs and were typically adversarial in nature and based on arms-length relations. Towards the end of 1980s firms involved in construction projects started to develop internal integration, which was then followed by the goal of external integration. This was achieved through engineering and construction firms integrating with their first tier suppliers. SCM is a concept that was developed from innovative models such as Just-In-Time (JIT) and originated in the manufacturing industry (Vrijhoef & Koskela 2000). It takes the integration initiatives to the next level with the aim of managing 'upstream and downstream relationships with suppliers and customers to deliver superior value at less cost to the supply chain as a whole' (Christopher 1998 pg. 15).

Vollman, Cordon & Raabe (1998) suggested that the construction supply chain should be an integrated set of practices aimed at managing and co-ordinating the whole supply chain from raw material acquisition right through to the customer. SCM seeks

improved performance through better use of internal and external capabilities in firms to create a seamlessly coordinated supply chain, thus elevating inter-company competition to inter-supply chain competition. SCM represents one of the most significant paradigm shifts of modern business management by recognising that individual businesses no longer compete as solely autonomous entities, but rather as supply chains (Chen & Paulraj 2004). SCM involves effective coordination and collaboration between all the parties involved in the supply chain, and tight-knit business relationships are central to the success of the supply chain network. The concept of business networks is known as 'relationships between businesses where the chain of connectedness is without limits and can span several relationships that are indirectly connected. It is closely tied to the concepts of partnerships, strategic alliances, and other cooperative relations with supply chain members (Bechtel & Jayaram 1997). The business relationships between supply chain partners and customers are especially important to manage and maintain, as the operation of a business is heavily reliant on incoming materials supply, the supply of information, distribution of products, and market demand.

Supply Chain Management (SCM) & Engineered-to-order (ETO) products

There has been limited operations and SCM research to date on the ETO supply chain (Hicks, McGovern & Earl 2000; Gosling & Naim 2009). The ETO supply chain is generally associated with large project based environments such as construction and capital goods. It is characterised as having the 'decoupling point' located at the design stage, so each customer order penetrates the design phase of a product (Gosling & Naim 2009). ETO products are typically highly customised as each individual order is produced in low volumes to meet individual project requirements. There is very limited research on the supply chain of prefabricated timber products. A number of studies have looked into ETO products from a supply chain perspective, including HVAC ductwork (Holzemer, Tommelein & Lin 2000) prefabricated concrete elements (Vrijhoef and Koskela 2000), transformers (Tommelein, Walsh & Hershauer 2003) and switchgear (Barker 1994).

Traditionally SCM has concentrated on high-volume manufacturing such as the automotive industry. In these high-volume industries the focus has been on the mass production of standardised products in routine and repetitive assembly processes. Four key trends have been identified including outsourcing of non-core activities, focusing on operations, reductionist in supplier base and establishment of long-term collaborative relationships with suppliers (Hicks et al. 2000). Research focuses on supply chains in which power is held by the focal producer who is typically able to exert a large degree of control over its smaller suppliers (Bresnen 1996). In ETO firms, relationships with suppliers differs considerably depending on different levels of vertical integration; variations in volume for different types of components; the degree of customisation of components; level of engineering required; proximity to critical path and the power balance between buyer and suppliers (Hicks et al. 2000). ETO firms are typically low volume producers in project-based environments, which means it is difficult to simply transfer SCM practices that were successfully adopted in high volume manufacturing industries.

Data collection and analysis

In this paper data collection was achieved through semi-structured interviews with 28 industry professionals with experience in prefabricated timber systems in Europe, Australia and NZ. The interviews were conducted in two rounds. Round one involved

semi-structured interviews to establish what are the major factors that effect the time and costs of prefabricated timber systems in non-residential construction. A thematic analysis was performed and a number of issues were highlighted. In Europe the major issues were ensuring good communication between building contractors and timber contractors. Bad weather and transportation/logistics throughout Europe were also highlighted as key issues that could effect time and costs. In Australia and NZ timber has traditionally been used in residential construction, with very little use in the non-residential market. It was outlined that a number of factors such as building code requirements, design and detailing, fabrication and installation capacity as being key factors. In Europe it was considered the supply of materials wasn't specifically an issue as there were a large number of firms that are vertically integrated and has enough production capacity to supply systems. In contrast in Australia and NZ it was highlighted that there is very little capacity of firms along the supply chain to procure prefabricated timber systems to the market at a competitive cost, time and quality.

Round two interviews were undertaken with 6 of the firms involved in the supply of prefabricated timber systems. Business models of a number of firms involved in the delivery of these systems are outlined in Table 1 and 2. When comparing models between firms in Europe, Australia and NZ it is important to highlight the different markets. Prefabricated timber systems have been produced in Europe significantly longer than Australia and NZ. With glulam being manufactured and fabricated into large structural components in Europe for over 100 years and CLT for around the last decade or so. Compare this to Australia where LVL has been manufactured for a couple of decades, and glulam since the early 1950's, though it has been labelled as a 'cottage industry'. Not only have timber systems been in manufactured for a significantly longer period of time in Europe, though the market is substantially larger. This large market allows a number of firms to be vertically integrated and offer a fully integrated solution to customers (see Table 1). Feedback from interviews highlighted that offering this 'solutions approach' is important in achieving time and cost objectives particularly in non-residential construction projects.

Table 1 - Different services offered/business models of timber companies in Europe

	Structural timber manufactured /fabricated		**Services offered**				
	CLT	Glulam	Full structural engineering design	Detailing /shop drawings	Design integrates with CNC	Logistics	Installation
Firm 1 (Italy)	X	✓	✓	✓	✓	✓	✓
Firm 3 (Switzerland)	✓	✓	✓	✓	✓	✓	X
Firm 4 (Austria)	✓	✓	✓	✓	✓	✓	X
Firm 5 (Austria & Germany)	✓	✓	✓	✓	✓	✓	X
Firm 6 (Austria and UK)	✓	X	X	✓	✓	✓	✓

In Australia and NZ the largest firms involved in timber construction are focused on commodity production for the residential construction market. This has occurred as there were no timber structural solutions available to compete with steel and concrete in non-residential construction so they were unable to penetrate this market. With the advent of new innovative prefabricated structural timber systems including EXPAN and CLT in Australian and NZ markets, timber products can have the opportunity to compete with traditional forms of construction in non-residential construction.

Table 2 - Different services offered/business models of timber companies in Australia & NZ

	Structural timber manufactured/fabricated		**Services offered**				
	Glulam	LVL	Full structural engineering design	Detailing /shop drawings	Design integrates with CNC	Logistics	Installation
Firm 1 (Australia/ NZ)	X	✓ (Manufacturing ONLY)	X	X	X	X	X
Firm 2 (Australia)	X	✓ (Manufacturing ONLY)	X	X	X	X	X
Firm 3 (NZ)	X	✓ (Manufacturing ONLY)	X	X	X	X	X
Firm 4 (Australia)	X	✓ (Fabrication ONLY)	✓	✓	✓	✓	X
Firm 5 (NZ)	✓ (Fabrication ONLY)	✓ (Fabrication ONLY)	X	✓	X	✓	X
Firm 6 (Australia)	✓ (Fabrication ONLY)	✓ (Fabrication ONLY)	✓	✓	X	✓	X

In the non-residential construction market traditional prefabricated solutions such as steel and prefabricated concrete have been delivered as a complete ‘solution’ to head contractors. Integrated models encompassing design and detailing, manufacturing/fabrication and installation are standard practice amongst these firms. In Europe timber companies supplying the non-residential market have similar models. In Australia and NZ the commercial construction environment is substantially different to the residential market, and if firms are to going to be successful in producing these new innovative systems time and cost competitively they need to structure their business’s to suit. Structural contingency theory outlines that there should be a fit between the organizational processes and the environment (Burns & Stalker 1966 and Lawrence & Lorsch 1967). It outlines that company models that match the environmental requirements should perform more successfully than those that don’t and under-performing companies may decide to adopt a new business model that better fits the environment. Research indicates that it requires significant capital costs and time to establish structural changes in organizational configurations and as a result companies rarely undertake the process. Large capital costs are typically required for vertical integration (VI) and this strategy is typically most suited to stable and mature environments. ‘The idea of VI is anathema to an increasing

number of companies. Most of yesterdays highly integrated giants are working overtime at splitting into more manageable, energetic units – i.e. de-integrating. Then they are turning around and re-integrating – not by acquisitions but via alliances with all sorts of partners of all shapes and sizes' (Grant 2007). Using these ideas as a base there is the possibility of adopting SCM strategies between a number of firms in the supply chain to offer an integrated 'solutions approach' for prefabricated timber systems.

SCM strategies

One of the most revolutionary changes over the past decade to affect the strategic management of supply chains is the rethinking of organisational structure to suit the demands of the market (Christopher 2011). In order to respond to market demands, organisations have restructured and a new form of organisation has emerged, where the supply chain is used as an extension of the organisation. When applying structural contingency theory to SCs it is suggested that the individual dimensions of the SC should be aligned in order to achieve the best fit for a particular environment. SCM initiatives such as partnering, strategic alliances, and joint ventures can be adopted to integrate the supply chain with the primary goal of increasing value for the end customer through achieving time and cost savings and quality improvements. There is growing evidence to suggest that supply chain integration can have a positive impact on operational performance outcomes such as delivery times, cost and quality (Rosenzweig, Roth & Dean 2003; Droge, Jayaram & Vickery 2004 & Flynn, Huo & Zhao 2010)

Partnering and the creation of strategic alliances could be used as short-term strategy for the prefabricated timber supply chain in Australia and NZ. This could help drive time and cost efficiencies, and offer the opportunity to achieve the closeness and co-ordination efficiencies similar to vertical integration without having to outlay significant capital investments (Beach, Webster & Campbell 2005). Partnerships and alliances between manufacturers, fabricators and designers could streamline the current fragmented SC and help minimise waste and delays. SCM literature typically limits supply chain integration to suppliers, although for ETO products the decoupling point' is located at the design stage, so each customer order penetrates the design phase of a product (Gosling & Naim 2009). For prefabricated timber systems it's important that the design team in particular the structural engineer have a close relationship with manufactures and fabricators to get a better appreciation for each other's challenges/problems, and capabilities. This collaboration will help drive better building designs and increased value to clients. A medium to long-term strategy could be for firms in the Australian and NZ industry to vertically integrate, similar to the business model of firms in Table 1. This long-term strategy of VI will be market driven and until there is a guaranteed stable market demand for such systems vertical integration by the one firm isn't a commercially viable option.

CONCLUSIONS

Prefabricated engineered timber structural systems for multi-storey non-residential construction are a new innovation to the construction industry in Australia and NZ and ensuring these systems can be delivered at a competitive cost and time is imperative to their successful commercialisation into the construction market. The supply chain for these systems is fragmented and primitive in nature. This is due to the lack of market demand for such systems. As a result firms haven't adopted the

organisational structures necessary to produce these systems effectively. Lessons can be learned from European timber firms as well as local steel firms whereby providing a complete solution approach to head contractors is critical to meeting commercial market needs and expectations. Firms in Australian and NZ could adopt SCM strategies such as partnering and strategic alliances to create an integrated supply chain for ETO prefabricated timber products. This research has made a number of discoveries, namely what the key issues are in relation to the delivery of prefabricated timber systems in Australia and NZ. It also established that the differences in business models between European, Australian and NZ firms involved in the delivery of prefabricated timber systems is due to market environments. Using structural contingency theory as basis this research outlined that by adopting SCM strategies such as partnering and alliances, firms along the SC can be restructured and create a new form of organisational form where the SC is used as an extension of the organisation. This will allow a fit between the organisational processes and the environment, and allow prefabricated timber systems the opportunity to meet the needs and expectations of the commercial market.

TENDER RULES AND TRUST INFLUENCE ON CO-OPERATION IN THE BUILDING INDUSTRY

Lene Faber Ussing[1] and Søren Wandahl[2]

[1]*Department of Mechanical and Manufacturing Engineering, Aalborg University, Denmark*

[2]*Department of Engineering, Aarhus School of Engineering, Aarhus University, Denmark*

ABSTRACT

The building industry has for many years been criticized for not having as efficient and effective co-operation as other industries. Some parties in the building sector try to use a new form of collaboration as i.a. partnering. In a big part of those partnering projects a good working relationship exists, the building owner is satisfied, the involved companies earn money and the project finish in time. A lot of projects do not use partnering or other new forms of collaboration. In these projects the general impression is that the parties in the building sector are fighting instead of co-operating. A questionnaire survey including building owners, contractors, suppliers, architects, engineers and client design advisor has been accomplished. The survey shows that the problem with co-operation among others is the way the tendering rules normally are used, where the normal assignment criterion is the lowest cost instead of the economically most advantageous bid. The involved parties do not always trust each other; the parties are not good enough at involving each other in the beginning of a project and the building sector is not ready enough for new forms of collaboration initiatives.

Keywords: assignment, co-operation, legislation, trust.

INTRODUCTION

The building sector is frequently described as conservative and tradition-bound, which according to critics results in little innovation, a not very efficient and effective cooperation and bad economy compared with other industries. (Akintola, et al. 2000, Cheung, et al. 2009, Dansk Byggeri 2006, Kadefors 2004, Wandahl, Cankaya et al. 2011)

Building projects involve to more or less extent a wide range of stakeholders. Some stakeholders can be one and the same person, others do not necessarily have a big influence on each building project, but they will be affected by the project. In the Danish case, the most essential stakeholders are the owner, the client design adviser, the architect, the engineer, the contractor and the supplier, who have the biggest influence on each building project, and they also have the biggest interest in the form of the project as it affects the economy in their companies.

[1] lf@m-tech.aau.dk

[2]swa@iha.dk

A traditional way of making a building project in Denmark is to organise it in five different phases: the planning phase, the project designing phase, the tendering phase, the construction phase and the operating phase respectively. This traditional way of organising a building project normally implies that some of the stakeholders are involved in the beginning of the project, others in the middle and the rest in the end of the project. This phase partition frequently results in none or a bad communication between the different stakeholders, which results in suboptimization of the economy. (Wandahl et al., 2007)

Until 2001 a Competitive Tendering Act existed in Denmark where you had to use price as criterion. This law still impact on part of the parties/stakeholders, therefore a big part of the building projects has seemingly put out to tender as a lowest price bid instead of an economically most advantageous bid. That again means that the parties are using traditional forms of contracts as contract awarded on a trade-by-trade basis, general contract and turnkey contract instead of using new forms of contracts as for instance partnering (Faber Ussing et al., 2011).

Another tradition in Denmark is to make one of a kind production. For a Dane it is important to have a building which differs from all other buildings, which results in new ways of building, often with a new composition of parties/stakeholders in the project.

Partnering and Lean Construction are some of the new ways of organising a building project to change the old traditional way of making a building project. Partnering and lean are ways where you try not to suboptimize on the economy but instead have common goals, a common vision, make the parties take common ownership and create a good communication between the parties involved in the project. (Ebbesen et al. 2007)

RESEARCH METHODOLOGY

The purpose of this paper is, by means of a hypothetical deductive method, to seek partly answer of the research question; *which contributory factors characterize the building sector as without good economy, efficiency and effective cooperation compared with other industries.* However, an inductive method is used in the survey. (Føllesdal, 2005)

Survey

To answer the research question two students from the M.Sc. in Construction Management at Aalborg University in Denmark have in their master dissertation conducted a questionnaire survey.

The idea was to use the most essential stakeholders: the owner, the client design adviser, the architect, the engineer, the contractor and the supplier as respondents in the survey. The respondents were intended to be selected with a comparative equal distribution between the six interest groups, and thus the respondents represent small, medium and large companies.

The survey was intended to be quantitative. Contact information was collected from 395 respondents in Denmark, whose designation of occupation fit in proportion to one of the six interest groups.

The survey is composed in SurveyXact which is an online analysis implement. The questionnaire was send to and accepted by 359 persons distributed as follows: 45 owners, 47 client design advisers, 68 architects, 74 engineers, 71 contractors and 54

suppliers. Hereof 163 respondents accomplished the questionnaire, 40 respondents partly accomplished the questionnaire and 156 did not answer the questionnaire.

The decision was only to use the 163 respondents who accomplished the full questionnaire. The grouping of the 163 respondents who accomplished was 21 owners, 31 client design advisers, 33 architects, 25 engineers, 36 contractors and 17 suppliers.

In the questionnaire the respondents first had to answer a question about which part they represent in the building sector. This was asked to be able to distinguish the subsequent questions according to which part the respondents represent. To the subsequent questions the Likert scale was used (Faarup et al., 2010).The questionnaire consists of 83 questions related to the research question; which contributory factors characterize the building sector as without good economy and without efficient and effective cooperation compared with other industries. Only the most unambiguous answers have been included in this paper.

FINDINGS AND DISCUSSION

Cooperating

Some of the questions in the survey were related to cooperating in the building sector. These questions shall clarify the respondents' general approach to cooperating in the building sector; if the respondents think it is possible to improve cooperation and find that good cooperation has an influence on a project economy.

The respondents were asked; 'To which extent do you think problems exist in the cooperation between the parties in the building sector?' The results in table 1 show that 63% of the respondents think problems exist in the cooperation to a great extent or a certain extent, but for the owners only 71% find that problems exist to a certain extent. Since the owner is a client in the building sector, the opinion of the owner is of paramount interest for cooperation.

Tabel 1. Cooperation between the parties in the building sector – To which extent do you think problems exist in cooperation between the parties in the building sector?

	Owner	**Client design adviser**	**Architect**	**Engineer**	**Contractor**	**Supplier**	**Total**
To a great extent	0,0% (0)	0,0% (0)	18,2% (6)	12,0% (3)	4,0% (1)	5,6% (2)	7,4 % (12)
To a certain extent	71,4% (15)	51,6% (16)	48,5% (16)	56,0% (14)	63,9% (23)	35,3% (6)	55,2% (90)
To a less extent	28,6% (6)	48,4% (15)	33,3% (11)	40,0% (10)	30,6% (11)	47,1% (8)	37,4% (61)
Not at all	0,0% (0)	0,0% (0)	0,0% (0)	0,0% (0)	0,0% (0)	0,0% (0)	0,0% (0)
Do not know	0,0% (0)	0,0% (0)	0,0% (0)	0,0% (0)	0,0% (0)	0,0% (0)	0,0% (0)
Total	21	31	33	25	36	17	163

Another question is; 'To which extent do you think it is possible to improve the cooperation?' To that question 39% answered to a great extent and 50% answered to a certain extent. Concerning cooperation and economy a question was; 'To which extent do you think that good cooperation has a positive influence on the project economy for the individual part of the building project?' To that question 66% answered to a great extent and 25% answered to a certain extent. This shows that cooperation is not optimal, but the respondents can see some opportunities and economic benefits by improving cooperation.

Matching of expectations

Another relevant topic is to find out to which degree the parties in the building sector match the expectations to each other in the project, obtain to a good cooperation without misunderstandings and mistakes.

Therefore the respondents were asked; 'To which extent do you think that matching of expectations between the parties in a building project can improve cooperation?' To that question 57% answered to a great extent and 33% answered to a certain extent.

The respondents all find that it is important to match expectations, but to the question; 'To which extent do you match expectations with the parties in a building project?' They are all asked this for every one of the five other parties. But the results of that question show, that even though they all find this important, they do not always carry it out in practice. The aggregate number for the parties is; Owner 78% to a great extent or a certain extent; Client design adviser 65% to a great extent or a certain extent; Architect 76% to a great extent or a certain extent; Engineer 70% to a great extent or a certain extent; Contractor 60% to a great extent or a certain extent; and Supplier 26% to a great extent or a certain extent. The disaggregate number shows the biggest match of expectations between the owner and the client design adviser, the architect, the engineer; a lower match between the advisers and the operating companies and the lowest match between the suppliers and all the others. The disaggregate number also shows that the suppliers think, they do a lower match of expectations to all others than all the other means they do the other way around.

Procurement rules

A topic of questions concern procurement rules. In this topic focus is on the influence of procurement rules on cooperation in the building sector, to which extent do the respondents think, that a change in the current procurement rules promote the cooperation between a building project's parties, and which assignment criterion is in the respondents opinion the most common for selecting parties in a building project.

The questions concerning procurement rules in table 2 shows that 61% find the procurement rules have a negative influence on cooperation in a building project to a great extent or a certain extent. The respondents were also asked; 'In which extent do you think that a change in the current procurement rules can promote cooperation between a building project's parties?' To that question 22% answered to a great extent and 36% answered to a certain extent. This shows that the main part of the respondents find, that the current procurement rules are not optimal, if a good cooperation is to be obtained.

Another question was; 'Which assignment criterion is in your opinion the most commonly used, when parties are selected for a building project? To that question 81%

answered, lowest price. This gives an indicator of that price and economy are very important for a lot of building owners.

Tabel 2. Procurement rules – To which extent do you think the procurement rules have a negative influence on cooperation between the parties in a building project?

	Owner	**Client design adviser**	**Architect**	**Engineer**	**Contractor**	**Supplier**	**Total**
To a great extent	23,8% (5)	12,9% (4)	15,2% (5)	12,0% (3)	16,7% (6)	35,3% (6)	17,8% (29)
To a certain extent	52,4% (11)	45,2% (14)	42,4% (14)	36,0% (9)	47,2% (17)	29,4% (5)	42,9% (70)
To a less extent	14,3% (3)	35,5% (11)	21,2% (7)	32,0% (8)	25,0% (9)	29,4% (5)	26,4% (43)
Not at all	4,8% (1)	3,2% (1)	6,1% (2)	12,0% (3)	8,3% (3)	0,0% (0)	6,1% (10)
Do not know	4,8% (1)	3,2% (1)	15,2% (5)	8,0% (2)	2,8% (1)	5,9% (1)	6,7% (11)
Total	21	31	33	25	36	17	163

Trust

Questions about trust in the building sector were a fourth topic in the survey. This topic was chosen to find out, to which extent the building sector is characterised by distrust, if trust can promote cooperation, and do the respondents think that it is possible to create more trust in the building sector.

One of the questions were; 'To which extent do you think the building sector reflects distrust between the parties on a building project?' To that question 18% answered to a great extent and 55% answered to a certain extent. The respondents were also asked to which extent they trust other parties in a building project. To that question the answers were; Owner 92% to a great extent or a certain extent; Client design adviser 75% to a great extent or a certain extent; Architect 88% to a great extent or a certain extent; Engineer 88% to a great extent or a certain extent; Contractor 59% to a great extent or a certain extent and Supplier 64% to a great extent or a certain extent. Those answers indicate some problems with trust between the parties in building projects. It also shows that the trust is highest between people who work closest together. It seems that trust is lowest between the parties in the construction phase. The answer shows that a big part of the owners (43%), the client design advisers (13%), the architects (42%) and the engineers (48%) have less trust to the contractor. The same is valid for the suppliers but not to such a explicit degree as for the contractors (owners 29%, the client design advisers 26%, the architects 24% and the engineers 48%)

The respondents were also asked; 'To which extent do you find that trust has a positive influence on cooperation between the parties on a building project?' To that question 79% answered to a great extent and 20% answered to a certain extent. Therefore it is important to create a trusting climate between the parties. Therefore the contractors and the suppliers have something to work with. Even if they just have a bad repu-

tation or there is a real problem; they are not as upright and trustworthy as others can wish.

Another question is shown in table 3. It shows that 76% of the respondents to a great extent or a certain extent find that it is possible to create more trust between the parties in a building project. It shows that there is a room for improvement of the trust level in the building sector.

Tabel 3. Trust in the building sector – To which extent do you think it is possible to create more trust between the parties in a building project?

	Owner	**Client design adviser**	**Architect**	**Engineer**	**Contractor**	**Supplier**	**Total**
To a great extent	9,5% (2)	9,7% (3)	24,2% (8)	8,0% (2)	36,1% (13)	17,6% (3)	19,0% (31)
To a certain extent	66,7% (14)	74,2% (23)	39,4% (13)	64,0% (16)	52,8% (19)	47,1% (8)	57,1% (93)
To a less extent	23,8% (5)	16,1% (5)	36,4% (12)	28,0% (7)	8,3% (3)	29,4% (5)	22,7% (37)
Not at all	0,0% (0)	0,0% (0)	0,0% (0)	0,0% (0)	0,0% (0)	5,9% (1)	0,6% (1)
Do not know	0,0% (0)	0,0% (0)	0,0% (0)	0,0% (0)	2,8% (1)	0,0% (0)	0,6% (1)
Total	21	31	33	25	36	17	163

Reciprocal understanding and respect

The last topic was to find out how the respondents consider the degree of reciprocal understanding and respect between the parties on one another's work.

The respondents were asked; 'To which extent do you find that reciprocal understanding and respect have a positive influence on cooperating in the building sector?' To that question 67% answered to a great extent and 32% answered to a certain extent. So it seems to be important to have a big degree of reciprocal understanding and respect between the parties.

But there is a problem because to the question; 'To which extent do you have experience with that the different parties do not have understanding and respect for you as a part of the project?' The aggregate answers are as follows: Owner 32% to a great extent or a certain extent; Client design adviser 44% to a great extent or a certain extent; Architect 37% to a great extent or a certain extent; Engineer 38% to a great extent or a certain extent; Contractor 47% to a great extent or a certain extent and Supplier 20% to a great extent or a certain extent. The disaggregate answers show that the respondents find that the contractors and suppliers have the lowest understanding and respect of the others work, the number from the owners is 47%, the client design advisers 58%, the architects 46%, the engineers 56% and the suppliers 25% to a great extent or a certain extent on the Contractor. The similar numbers on the suppliers are from the owners 35%, the client design advisers 47%, the architects 53%, the engineers 47% and the contractors 55% to a great extent or a certain extent. This shows that there is a problem about reciprocal understanding and respect between the parties on one another's work, especially between the advisers and the operating companies.

CONCLUSION AND FURTHER RESEARCH

The purpose of this paper was to answer a part of the research question; which contributory factors characterize the building sector as without good economy and without efficient and effective cooperation compared with other industries. To answer a part of the question a questionnaire survey was made inter alia the topics cooperating, matching of expectations, procurements rules, trust and reciprocal understanding and respect. The most essential stakeholders in the building sector; the owner, the client design adviser, the architect, the engineer, the contractor and the supplier were respondents to get a wide sense of the opinion in the building sector in Denmark.

The results of the survey show that the parties in the building sector think, there are problems with cooperation on a building project. It was also widely agreed that it is possible to improve cooperation, and that a good cooperation has a positive influence on the project economy for the individual part in the building project. It shows that the Danish building sector is aware of the problems with cooperation, and they know that the problems must be addressed in future, hopefully with an economic benefit as result (Faber Ussing, 2010).

Matching of expectations is also important in the respondents' opinion. A good matching of expectations between the parties in a building project can improve cooperation, but the respondents are not very good at doing it themselves. The results show the biggest match of expectations between the owner and the advisers, a lower match of expectations between the advisers and the operating companies and the lowest match between the suppliers and all the others.

The tendering legislation has changed in Denmark, so since 2001 all public building projects are now assign to either the Tendering Rules in EU or the Danish Tender Law (looks like the Tendering Rules in EU). (Ussing, 2008) A lot of Danes find the Tendering Rules in EU very bureaucratic (Faber Ussing, 2010), compared to how the Danes normally act; therefore the respondents were asked if they find that the procurement rules have a negative influence on cooperation on a building project. The respondents find that the rules have a negative influence, but they also find that changes in the rules can have a positive influence on cooperation. Most of the respondents still use the assignment criterion lowest price, so instead of changing the rules, we could start by changing the assignment criteria from lowest price to the economically most advantageous bid, and use assignment criteria as good cooperating and trust to obtain a better cooperation with an economic benefit as result.

The respondents think that trust is important between the parties in the building project to obtain good cooperation. They also find that the trust in the building sector can be improved. Now the trust is highest between people who work closest together. It seems as if the trust is lowest between the parties in the construction phase. Therefore the contractors and the suppliers have something to work on. Even if they just have a bad reputation or there is a real problem; the other parties certainly think that the contractors and suppliers are not as upright and trustworthy as others can wish (Wandahl, Bejder et al., 2011).

Reciprocal understanding and respect goes hand in hand with trust. Therefore the results on that topic are not surprising. The respondents find that on high reciprocal understanding and respect are important to obtain good cooperation on a building project. But something which surprises is that even the respondents find a high reciprocal understanding and respect important, they do not have it in practice. As with the trust the other parties it means, that the contractors and suppliers have a low reciprocal un-

derstanding and respect of others' work. For the other parties the number in the survey is higher but not high enough to conclude that there is no problem.

ACKNOLEDGEMENT

This work in this paper has been carried out in collaboration with Nich Nielsen and Kasper Lyngsø, who have made the practical questionnaire during their final dissertation for M.Sc. in engineering with specialisation in construction management.

THE IMPACT OF CONTRACTORS' TECHNICAL CAPABILITY ON COST AND TIME PERFORMANCE OF BUILDING PROJECTS IN NIGERIA

Isaac Olaniyi Aje[1] and Ibukun Oluwadara Famakin[2]

[1,2]*Department of Quantity Surveying, Federal University of Technology, Akure, Nigeria*

ABSTRACT

Technical capability is one of the major criteria for evaluating construction contractors during prequalification and tender evaluation. This paper investigates the impact of contractors' technical capability as a prequalification criterion on cost and time performance of selected building projects. Prequalification assessments on technical capability of wining contractors as well as cost data relating to 77 completed building projects were obtained. The data were analyzed using One-way analysis of variance (ANOVA) and multiple regression. The resulting p-values are 0.937 and 0.011 for cost and time performance respectively indicating that contractors' technical capability has significant impact on time performance while it has no significant impact on cost performance of building projects. Models capable of predicting the final cost and duration of building projects were eventually derived with R^2 value of 96.2% and 90.01% for cost and time respectively; thus signifying high predictive efficacy of the models. The result of the research would therefore for a good basis for predicting realistic cost and time for building projects; while also enhancing objective assessment of candidate contractors during prequalification and tender evaluation.

Keywords: Cost, Impact, Technical Capability, Performance, Time, ANOVA.

INTRODUCTION

The construction industry is a very unique industry when compared with other industries and it is one of the largest industries in most developed economies (Odeyinka, 2003). The structure of the industry is also complex in that it has a wide range of types of contractors comprising main and sub-contractors; low technology firms and sophisticated specialists, builders and civil engineers; and a whole range of professionals connected with the industry (Hillebrandt, 1985). The construction industry also has some distinct characteristics which separate it from all other industries. This according to Harvey and

[2] famibuks@yahoo.com

Ashworth (1993) includes the physical and investment nature of the product and the arrangement of the industry where design has normally been separated from construction.

Construction projects are one-off endeavors with many unique features such as long period, complicated process, abominable environment, financial intensity and dynamic organizational structures which also generate technological complexity (Zou, Zhang & Wong, 2007). Considering the complex nature of the construction process, contractor performance is significant to the success of any construction project because it is the contractor who converts designs into practical reality (Xiano & Proverbs, 2003). This therefore calls for a sound technical competence of construction contractors to withstand the challenges associated with variable construction activities as well as project performance objectives of time, cost and quality. Contractors engaged in construction business should therefore possess cognate technical capability in terms of equipment and personnel for the execution of any construction project that may be committed to their hand.

Therefore, the construction clients' decision most impacting the superlative value criteria is that of selecting the appropriate contractor (Holt, 1998). The most commonly used criteria for contractors' selection according to Hatush and Skitmore (1997) are those pertaining to financial soundness, technical capability, management capability, health and safety performance, and past performance of contractors. Out of these criteria, contractors' technical capability is one of the most important criteria always considered critical to achieving required quality of projects. Thus any contractor that lacks adequate technical personnel or technical know-how is likened to a vehicle without engine**.** The Bureau of public procurement in Nigeria mandated it for government agencies and parastatals seeking to procure construction projects to ensure prequalification of contractors prior to contract award.

However it has been observed that prequalification assessment of contractors often confirms that prequalified contractors have great potentials to perform if awarded the contract. Despite this, there has been no commensurate improvement in the success rate of construction projects in terms of quality, time and cost. Considering the foregoing therefore a system of predicting cost and time performance of construction projects based on prequalification performance of contractors on technical capability would be worthwhile. This is will assist prequalification assessors/construction practitioners to carry out objective assessment of contractors during prequalification which will in turn assist clients to consider the most viable contractor for contract award in.

LITERATURE REVIEW

The technical capability of contractors is the ability of contractors to employ relevant skills and expertise in terms of technical know-how and equipment capacity to project management with the objective of ensuring project delivery to the desired quality specification within the budgeted cost and time schedule (Aje, 2008). It generally relates to contractors' experience, plant and equipment capacity, the volume and quality of personnel and their general ability. Experience gives insight to the contractors' potential by determining the ability of contractors to commit adequate resources to a large project.

Three things relevant to this variable according to Holt *et. al.* (1994) includes a firm's structure (national or local), the extent of catchments and the firm's mobility potential. A national company will have greater geographical experience which may have been achieved through a network of regional offices. Therefore a national company has wider catchments and hence greater ability to tackle certain types of contract e.g. maintenance contract for a client with properties nationwide.

Furthermore, the suitability of plant and equipment are vital to construction success (Wong & Holt, 2003). Mustapha and Ruan (1990) opined that the availability and suitability of plant can affect the decision of construction clients in selecting a contractor. Staff quality and their experience are also crucial to successful project outcome because the quality of supervisory personnel assigned to a contract reflects heavily on the total efficiency of a contractor's efforts (Holt *et. al.,* 1994). For example a manager who has spent over 25 years trained with and come through the ranks with one particular company is desirable because this facilitates interdepartmental training and a greater familiarity of the company organizational structure (Harris and McCaffer, 1995). Scoring of these criteria is achieved by observing what percentage of the contractor's senior management meet these criteria.

The award of contract to a competent contracting organization should therefore ensure effective delivery of construction project to time, cost and quality standard. Chua *et al* (1999) asserted that it is generally accepted that the major goals in any construction project are budget, schedule and quality. Corroborating this view, Russell *et. al.* (1997) opined that the overall success of a construction project includes meeting goals related to cost, schedule and quality. Therefore the objective of taking all the required precautions and "due process" in the selection of contractor for construction project execution is to ensure performance of the project in relation to the above mentioned variables. Chua *et. al.* (1999) identified proper contractual arrangements as one of the important success factors for construction projects. This implies that the engagement of contractors with track record of technical and managerial capability should enable clients and the project team members achieve the objectives set for the project. Cheung *et. al.* (2004) also noted that selecting a competent contractor is paramount to successful delivery of construction project. Therefore the competence of any contractor in terms of its technical capability, experience and managerial ability reflects heavily on the performance of the project. Unfortunately in Nigeria, in spite of the compulsory prequalification of contractors prescribed by the bureau of public procurement, quality of construction projects has remained unsatisfactory while projects are completed beyond the scheduled time with its attendant cost overrun. This has begin to generate questions from members of the public and stakeholders within the construction industry whether the prequalification exercise really has effect on the performance of the projects or whether the evaluation of the contractors during prequalification exercise is being carried out objectively. It is now expedient on the part of stakeholders in the Nigerian construction industry to ensure that mediocre are weeded out of the Nigerian construction industry. This will enable the government and the private sector client to have value for their huge investment in construction activities.

RESEARCH METHOD

The research area comprised two major Nigerian cities: Abuja and Lagos. These cities were selected because majority of construction practitioners, clients and contractors have their operation office in these two cities. More importantly, Abuja is the seat of government where a lot of development in terms of construction is going on while most of the policy makers also reside there. Due to quantitative nature of this study and bearing in mind the study objectives, data for the study were sourced through a combination of opinion-based questionnaire survey for primary data and from archival materials for secondary data. The preliminary section of the questionnaire was on background information about the respondents. These were required to assist in classifying the firm's size and the experience of the respondents while other sections address the main issues of the study. The prequalification criteria derived from the literature as potential criteria used for contractors' prequalification were also listed. Respondents were then requested to score their opinions on a 0-5 likert type scale, zero being included so as to accommodate the instances where the criterion was not applicable (Holt, 1997). Archival data relating to prequalification assessment of contractors on technical capability, initial contract sum, planned contract duration, completion cost and actual contract duration of completed building projects were also sourced from consultant Quantity Surveyors.

The target population for the study comprised core building professionals involved in the procurement of building projects. These include Architects, Structural Engineers, Quantity Surveyors, Builders and Services Engineers. In order to have an accurate sampling frame, the lists of all professionals who are financial members of their respective professional institutions and based in the study area were used. Data relating to contractors were also sourced from the list of contractors accredited by the Nigerian Institute of Building (NIOB) as published in the register of contractors (2003). In all a sampling frame of 1,355 was gotten representing the total population of the study.

Based on this, the sample size was calculated from the following formula as used by Shash and Abdul-hadi (1992)

$$n = \frac{n^l}{1 + \frac{n^l}{N}}$$

Where n = sample size: $n^l = \frac{S^2}{V^2}$

N = Total population, V = Standard error of sampling distribution = 0.05,
S = the maximum standard deviation in the population elements, P = the proportion of population elements that belong to the defined class

From the above formula, the sample size for the various categories of respondents was therefore found to be 427.

Having defined the study population, the research adopted random sampling technique. A total of 194 questionnaire were collected out of 427 questionnaire distributed while archival data on 77 completed projects were also sourced directly from the consultant Quantity Surveyors. The response rate represents 45.43% of the sample size which is far

above the norm of 20-30% response rate in questionnaire survey of the construction industry (Akintoye and Fitzgerald, 2000).

Prior to data collection, pilot study was carried out using the initial draft of the questionnaire to ensure that the research instrument will establish the most productive form of data analysis. This was achieved by administering the draft questionnaire to 10 selected Subject Matter Experts (SMEs) from the academics and the private practice. The content validity of the research instrument was therefore tested using the content validity ratio developed by Lawshe (1975) as follows:

$$CVR = \left(n_e - \frac{N}{2}\right) \Big/ \frac{N}{2}$$

Where:
CVR = Content Validity Ratio
n_e = number of SMEs indicating that an item is essential
N = total number of SMEs

For the content of a research instrument to be valid the CVR must ranged from 0.99 - 0.51 for 5 to 14 SMEs (Lawshe, 1975). The average content validity ratio calculated is 0.86 indicating that the content of the research instrument used for this study is valid. Reliability test was also conducted on the research instruments using Cronbach's alpha (α). According to Nurosis (1992) a figure of α near to 1 shows higher reliability. The reliability coefficients for the instrument relating to variables of contractors' technical capability and the archival data were found to be 0.772 and 0.959 respectively. This signifies that the instruments used for the study were reliable. The aspects of the questionnaire relating to background information of respondents were analyzed using percentiles. Secondly, the evaluation of the main criteria for contractors' prequalification was carried out using mean score while Analysis of Variance (ANOVA) was used in determining the impact of contractors' technical capability on cost and time performance of building projects. Moreover, the relationship between contractors' technical capability and construction project performance was established with the aid of linear regression.

RESULTS AND DISCUSSION

Background Information of Respondents

Table 1 shows the summary of the background information about the respondents. It is observed from the Table that 35.6% of the respondents have postgraduate qualifications while about 64.4% have minimum of Higher National Diploma in their various fields of study. Furthermore about 9.8% of the respondents are Fellow members of their respective professional bodies, 71.1% and 19.1% of them are also Corporate and Graduate members of their professional bodies respectively. Moreover, the respondents have an average of about 17 years experience in the construction industry and have also participated in at least 11 prequalification exercises within the last three years. This analysis therefore suggests that the data provided by the respondents can be relied upon for the purposes of analysis.

Table 1: Summary of Background Information of Respondents

Category	Classification	Frequency	Percentage (%)
Academic Qualification	HND	27	13.9
	B.Sc/B.Tech	98	50.5

Variables of Contractor's Technical Capability

From Table 2 respondents were of the view that contractors' technical experience and ability is of utmost importance when evaluating contractors' technical capability during prequalification exercise. This without doubt, will influence the technical performance of the contractor in the proposed project. The number and quality of plant and equipment possessed by the firm was surprisingly rated higher than the quality of workmanship. This may be as a result of the fact that the ability of workmen to work judiciously to produce quality product depends on the conditions of plants and equipment while the success of construction works in terms of meeting schedules and ultimately achieving optimum cost performance depends on the type and capacity of equipment used. Even though majority of contractors in Nigeria except the few ones who are well established does not have most of the basic equipment and construction plants needed for

construction works. Rather they depends on plant hire which are not usually indicated in the documents submitted for prequalification, this may have also influenced the subjective assessment of plants and equipment under contractors' technical capability.

Furthermore, the fact that majority of the contractors depend on equipment hire, as against the number of equipments they claimed to own may have being one of the major reason why their technical performance on site does not usually match their ratings on technical capability during prequalification evaluation. The ratings of clients on plants and equipment also confirm that the clients are aware of the fact that most construction contractors usually depends on plant hire. The p-values generally show that there is no agreement among the respondents in the ranking of the variables of technical capability. However, because of the government legislative protection of local or indigenous technology as specified under the local content emphasis, level of technology was not ranked high as compared with contractors' experience and quality of equipments. This may also be the reason why contractors ranked level of technology least in their ranking. The idea according to most contractors interviewed is that level of technology is insignificant if quality and time schedule can be met, they further confirm that Nigerian contractors are gradually improving on their level of technology.

Impact of Contractor's Technical Capability on Construction Project Performance

Tables 3 and 4 show the results of the one way analysis of variance of the impact of contractors' technical capability on cost and time performance of construction projects. From Table 3 the observed value of F is 0.066 and p-value is 0.937. In Table 4, the F-value as observed is 4.808 and the p-value is 0.011. The result shows that the technical capability of contractors has no significant impact on cost performance of construction project since the p-value is greater than 0.05 (p-value = 0.937). On the other hand, the p-values of 0.011 observed in Table 4 is less than 0.05 at 95% confidence level signifying that the Contractors' Technical Capability has significant impact on time performance of construction project.

Table 3: One-way Analysis of Variance on the Impact of Contractors' Technical Capability on Cost Performance

Within Groups	74	29769.559	402.291			
Total	76	33637.85				

***Significant at p < 0.05**

The significant impact of contractors' technical capability on time performance may be as a result of the fact that contractors' experience and ability as well as quality of plant and equipment are considered important to technical capability as can be seen in Table 4,

which according to Mustapha and Ruan (1990) are crucial to successful project outcome. Generally, the technical capability of contractors in terms of quality of plants and equipment, the contractors' experience and ability has direct relationship with construction project time performance. This is because the availability of plants and equipment has direct effect on contractors' progress on site while at the same time improving the morale of the technical staff to ensure that there is general progress on site, which in turn bears on the techniques of executing the job to achieve quality product resulting to high productivity.

The Relationship between Contractors' Technical Capability and Performance of Construction Projects

A major objective of this study was to determine the relationship between contractors' technical capability and performance of construction projects in terms of cost and time. Such relationship would assist construction clients' and practitioners in determining how this criterion is likely to affect project objectives in terms of cost and time prior to contract award. This will benefit contractors by helping to eliminate incompetent contractors and thus creating fairer competition among contractors. Therefore, data on initial contract sum, completion cost, planned contract duration and the actual contract duration as well as prequalification assessment of contractors on technical capability sourced from consultant Quantity Surveyors were employed. The technical capability of contractors was assessed jointly by a team of consultants and the client during prequalification evaluation based on the prequalification documents submitted by the contractors. The information provided by the contractors were subsequently confirmed by inspecting past projects executed by the contractors and a visit to their various offices. Information from the clients who have worked with the contractors in the past were used to substantiate the claims of the contractors. This technical capability in respect of each contractor was rated on a point scale of 20 as prescribed by the bureau of public procurement and was later transposed to 100 percent by multiplying the scores of each contractor by 5. Therefore the relationship between contractors' technical capability and completion cost is thus presented as:

$$Pcc = -22599787.9 + 1326027.04Tc + 0.987Ics + 15318.82Pcd + e \quad \text{..... (i)}$$

($R = 0.981$, $R^2 = 96.2\%$, Adjusted $R^2 = 95.9\%$)

Where,
Pcc = Project completion cost,
Tc = Technical capability
Ics = Initial contract sum
Pcd = Planned contract duration, and
E = Error term

A widely used measure for the predictive efficacy of a model is its coefficient of determination, or R^2 value which according to Xiano and Proverbs (2005) measures the strength of the linear association between two or more variables. If there is a perfect relationship between the dependent and independent variables, R^2 is 1. In case of no relationship between the dependent and independent variables, R^2 is 0. The predictive efficacy of the cost performance model was found to be very high with an R^2 value of 0.962 and adjusted R^2 of 0.959. This result indicates that the project completion cost is

positively related to contractors' technical capability at the level of significance of 0.0001. Moreover the *F* statistic of a model basically tests how well the model, as a whole accounts for the dependent variable's behaviour. However, the constant estimate for this model is not significant (p = 0.349) signifying that the constant value do not significantly contribute to the model. The *F*-value of this particular model was found to be statistically significant at less than the 0.0001 level. The regression analysis results are summarized in Tables 5 and 6.

Table 5: Result of multiple regression analysis of the cost performance prediction model

R	R^2	Adjusted R^2	Std. error of est.	F	Sig.
0.981	0.962	0.959	19249569.35	487.910	0.000

Predictors: (Constant), Technical Capability, Initial Contract Sum, Planned Contract Duration.

Table 6: **Coefficients in the Model**

Variables in the Equation	β	Std. Error	Beta	t-stat.	Sig.
Constant	- 22599787.87	2.3×10^8		-0.943	0.349
Technical Capability	1326027.04	1.4×10^7	-0.002	0.935	0.003
Initial Contract Sum	0.987	0.031	0.977	2.026	0.000
Planned Contract Duration	15318.82	19794.09	0.020	0.773	0.002

Moreover, the regression equation for the final contract duration from which the project time performance can be determined is stated as:

$Acd = -27.682 + 4.267Tc + 1.79 \times 10^{-7} Ics + 1.008Pcd + e$…….2

($R = .949$, $R^2 = 90.1\%$, Adjusted $R^2 = 89.6\%$)

Where,

Acd = Actual contract duration
Tc = Technical capability
Ics = Initial contract sum
Pcd = Planned contract duration, and
E = Error term

The predictive efficacy of the model as defined by the R^2 value is 0.901 while the adjusted R^2 is 0.896. The *F*-value of the model was also found to be statistically significant at less than the 0.00001 level indicating a high degree of fitness of this model. Also the p – value of the constant estimate of 0.686 implies that the constant value do not contribute significantly to the model. Tables 7 and 8 summarize the result of the regression analysis.

Table 7: Result of multiple regression analysis of the time performance prediction model

R	R^2	Adjusted R^2	Std. error of est.	F	Sig.
0.949	0.901	0.896	1.58×10^5	175.668	0.000[a]

Predictors: Constant, Technical capability (Tc), Initial contract sum (Ics), Planned Contract duration (Pcd).

Table 8: **Coefficients in the Model**

Variables in the Equation	β	Std. Error	Beta	t-stat.	Sig.
Constant	27.681	68.106		-0.157	0.686
Technical Capability	4.267	4.031	0.046	0.822	0.002
Initial Contract Sum	1.79×10^{-7}	8.83×10^{-8}	0.098	2.398	0.001
Planned Contract Duration	1.007	0.056	0.903	18.608	0.000

Model Validation

Tables 9 and 10 show the results of the regression test on the cost and time performance models respectively. In Table 9, the coefficient of determination as defined by the R^2 value is 0.995 while the intercept and the slope are - 2.61 x 10^{-7} and 1.00 respectively.

Table 9: Regression result between the observed and the predicted cost

R	R^2	Adjusted R^2	Intercept	Slope	Sig.
0.997[a]	0.995	0.994	-2.41 x 10^{-7}	1.00	Not Sig.

Table 10: Regression result between the observed and the predicted duration

R	R^2	Adjusted R^2	Intercept	Slope	Sig.
0.904[a]	0.818	0.804	-9.73 x 10^{-5}	1.03	Not Sig.

Also in Table 10, the R^2 value is 0.818, the intercept is -9.73 x 10^{-12} and the slope is 1.03. It then follows that there is no significant difference between the observed and predicted values of the cost and time performance models. Therefore the models developed in this study can accurately predict cost and time performance of construction projects since the result of the regression test carried out agree with Ogunsemi and Jagboro (2006).

CONCLUSION

This study has clearly shown that contractors' technical capability is an important criterion for evaluating potential performance of construction contractors during prequalification and tender evaluation. Also the study identified past performance and quality achieved, contractors' experience, management knowledge and quality control programme as the major variables for evaluating contractors' technical capability. The study further revealed that contractors' technical capability has significant impact on cost and time performance with a p-value of 0.042 and 0.039 respectively. This therefore corroborates the reason why technical capability was considered important among the important criteria for contractors' prequalification in Nigeria. The study also shows that construction project cost and time performance is correlated with contractors' technical capability. Based on this, predictive models for project completion cost and actual contract duration of building projects was established and validated. This will enable consultants and clients determine the cost and time performance of construction projects based on prequalification assessment of contractors on technical capability, the contract duration and tender figure quoted. This therefore implies that it is possible to forecast the actual contract period and completion cost of projects right from the onset based on the aforementioned variables. This will therefore provide early sign of contractors' likelihood performance to clients and consultants before the final award decision. It is believed that the practical application of these models will significantly enhance their improvement thereby ensuring the selection of the most competent contractors for construction projects.

ABSTRACT

Government of Malawi is concerned with the rate of failure of public construction projects in the past ten years. Successful execution of construction projects depends on procurement methodology. Therefore, this study aims at investigating the processes and factors considered when conducting the procurement of public construction projects in Malawi. It also measures readiness of the procurement practitioners in particular organisations to change the procurement systems. Analysis of quantitative survey data reveals that there is significant consistency across public sector agencies in the nature of procurement practice. Although the analysis did not prove that the donor procurement rules and adherence to traditional procurement were inducement to project failure, respondents unanimously denounced donor procurement guidelines; instead they advocate for launching of concurrent engineering system of procurement. The study confirmed that the failure rate of construction projects stood at approximately 40%. Based on the findings, the study proposes that the procurement legislation should be reviewed to allow for flexibility on the approach to construction procurement.

Keywords: integrative, Malawi, performance, procurement, public.

INTRODUCTION

Selecting the most appropriate organisation for design and construction work represents a fundamental aspect of the modern construction procurement process (Turner, 1997: 327; Ashworth, 2002: 53). Increasingly, the integrated client team includes facilities management practitioners (particularly those concerned with client strategic issues in the organisation) who need to be familiar with the expanding range of procurement options now on offer (Masterman, 2002: 8). Within this process, many researchers agree that "design", "management" and "construction" can theoretically be viewed as discrete parts, although in reality some synergy and overlap does exist (Best and de Valence, 1999: 72;

Walker and Hampson, 2003: 97). For this reason, categories of procurement methods have been classified around three distinct activities:

- Traditional systems (including cost-plus, provisional quantities);
- Design and build systems (including design, management and construction, and novation);
- Management-oriented systems (including design and manage, management contracting and construction management).Selecting an appropriate procurement path is a complex and daunting task for both the client and the client's advisers and remains an enigma for many researchers, as evidenced by the volume of research conducted in this subject area (Franks, 1984: 113; Bennett and Grice, 1990: 20; Chan, Scott and Lam, 2001; Cheung, Lam, Leung and Wan, 2001; Masterman, 2002: 54). It is often recommended that the choice of procurement route should be based on the client's objectives and priorities (Turner, 1997: 329) as well as engineering, economic, environmental and social considerations (Love, 1996: 329). The most common criteria found in literature concerning the choice of procurement methods include time, certainty, flexibility, quality, complexity, risk, price competition, responsibility, and dispute and arbitration (NEDO, 1985: 20; Skitmore and Marsden, 1998: 71; Love Skitmore and Earl, 1998: 1). Notably, research on procurement selection has tended to focus on Western construction industries with limited research being undertaken in developing countries (Love et al., 1998: 5). The Malawian construction industry currently has an infamous reputation for being inefficient and lacking in effectiveness (National Construction Industry Council, 2010: 23) as evidenced from the results of this research. In response to this the paper uncovers facts about processes leading to such failures.

Objectives of the paper

The rate of failure of construction project may be an indication of weak configuration in the way the projects are managed from conception to close out. The interest of this paper is the conception phase of the project (procurement planning) with the objective of investigating the procurement practices and possible impacts on the outcomes in terms of client satisfaction criteria. Increasing the achievement of these criteria has been associated with the method of procurement (Love, Skitmore and Earl, 1997: 221). To this end, the variables investigated include: cost, time, risk allocation, quality, complexity and uniqueness of a project. It also investigates the procurement experts' inclinations in considering organisational setups (culture, stakeholder involvement, value for money etc) when selecting a method of procuring construction projects. The associated research questions are:

- What percentage of public construction contracts fail to be delivered successfully?
- Do the procurement practitioners perceive that project sponsor's (debt/grant financing) procurement methods contribute to the mundane performance of the public projects?
- Do practitioners believe that there is a relationship between the integrative approach to procurement (stakeholder involvement) and the outcomes of public projects delivery?
- What are the factors influencing the choice of procurement assessment criteria in Malawi?

- What is the altitude of public procurement specialists towards departure from the inherent traditional procurement to integrate concurrent engineering system of procurement in Malawi?

The paper further interests the respondents to state their level of willingness to adopt other methods of public procurement thereby insinuating change to the Procurement Law of Malawi.

CONCEPTUAL FRAMEWORK AND POLICY CONTEXT

The design and construction of buildings must attain a compromise in the circumstances existing at the time of conception between product, programme and price (quality, time and cost) (Ashworth, 2002: 57; Walker, 2002: 28). Client and project characteristics, as

well as the individual project requirements, are strongly related to procurement method selection. The National Economic Development Office (NEDO) (1985: 25) has set down probably the most important procurement assessment criteria (PAC) to guide assessment of client's priorities. In fact, the nine criteria identified by NEDO can be regarded as the most important framework used for assessing client's priorities and has been employed directly or indirectly by many researchers (Skitmore and Marsden, 1998:71), Turner (1997: 328), Love et al, (1998: 3), Cheung et al, (2001: 427), Chan et al, (2001:710) and Chang and Ive, (2002: 276). Although previous studies did not use identical PAC, it is clear that a consensus of opinion suggests that the most suitable PAC does exist among the researchers (Chang et al, 2002: 275). Table 1 contains the most commonly used project criteria with the early work by NEDO providing nine of these; speed (time), price certainty, flexibility, quality level, complexity, risk avoidance, price competition, responsibility, and dispute and arbitration (National Construction Industry Council, 2010: 25).

RESEARCH DESIGN AND METHODOLOGY

The main research method is quantitative. The research was conducted using the practitioners from client organisations as research subjects. However, analysis of the results required interpretive and deductive reasoning more akin to qualitative approach. The selected organisations were primarily responsible for procurement methods selection in the delivery of public sector projects such as housing, water, buildings, power and roads. The main research strategy employed is the evaluation study with theory building connection using deductive reasoning. In order to obtain a comprehensive view of procurement practices across the Malawi's public sector, the survey instrument was emailed to lead procurement staff in organisations who conduct heavy construction across the public sector. The respondents were identified by what can be described as an opportunist sampling. That is, the office of the director of public procurement (ODPP) identified a number of stakeholders from their own experience in Malawi (since there are no formal records of public sector organisations which typically deal with construction

and its procurement). Staff contacted came form the following public departments the ODPP, procurement staff of the Roads Authority, the Procurement Specialists from the Malawi Regulatory Authority, the Malawi Housing Corporation, Ministry of Irrigation and Water development, Blantyre Water Board, Central Region Water Board, Northern Region Water Board, Southern Region Water Board, the Ministry of Education, Ministry of Agriculture and ESCOM. Twenty one percent of the selected practitioners spend more than MK1 billion (US$6 million) per year. The persons that were selected to complete a structured questionnaire were primarily responsible for procuring and delivering public sector construction projects such as housing, roads, water supply and power.

The questionnaire elicited views on general experience, knowledge, opinions, viewpoints and willingness to adopt other methods. A total of 40 survey questionnaires were distributed to key stakeholders within the industry including 2 respondents who tested the survey in a pilot study, and a total of 26 survey questionnaires where received back.

Respondents were requested to assess each criterion on a Likert scale of 1 to 5. The five-point scale was transformed into relative importance indices for factors in some of the research questions, using the above method, to determine the ranks of the different factors. These rankings made it possible to cross-compare the relative importance of the factors as perceived by the respondents. Hypotheses were also tested to validate or invalidate earlier assumptions. Areas covered include the research design, population, data collection and analysis and plan of activities.

Limitations and assumptions of the study

- The analysis is exclusively on the procurement of construction contracts in the public sector;
- The analysis will focus on construction procurement and project performance areas only;
- The time frame for the study spans from 2003 to 2011;
- The number of respondents can be viewed as a limitation but it should be kept in mind that the construction industry in Malawi is relatively small and limited numbers of people participate in public construction procurement.
- Procurement is a new field in Malawi and not much has been published.

 ISBN: 978-1-84219-840-7 .

FINDINGS AND DATA ANALYSIS

Content analysis was used to determine the underlying reasons as to "how and why" the selected public sector agency selected a particular procurement method for its construction projects. The data derived from the questionnaire was entered into SPSS (Statistical Package for the Social Sciences). Five main themes emerged and were used to analyse the data: organisational setup (including culture, project approach vis-à-vis efficiency), procurement selection factors, and influence of donor procurement systems, level of involvement of project stakeholders and donor funded projects' procurement rules and are reported under the subsequent paragraphs. Data from the questionnaire were extracted and the scores of criteria reported on for all respondents (Figure 1 to right and 2 below) as can be seen, out of the nine factors discussed in Section 2 above, the factor with the highest score given by all respondents is time (68%), followed by degree of complexity (67%) and uniqueness of a project (64%), the lowest is risk about the project (62%)

The results of the analysis on obstacles in attaining project triple bottom objectives: respondents have identified four main obstacles with "focus on short term goals topping the list.

The other three (in diminishing significance) are: lack of ethics, project focus and not process focus and lack of stakeholder consultation. With regard to practitioner's opinion of the degree of causation of failure by certain nominate factors, the respondents selected the following in descending order of significance: Poor project communication and information technology and absence of risk management, level of sponsors involvement, and lack of monitoring plan. However, plotting the factors

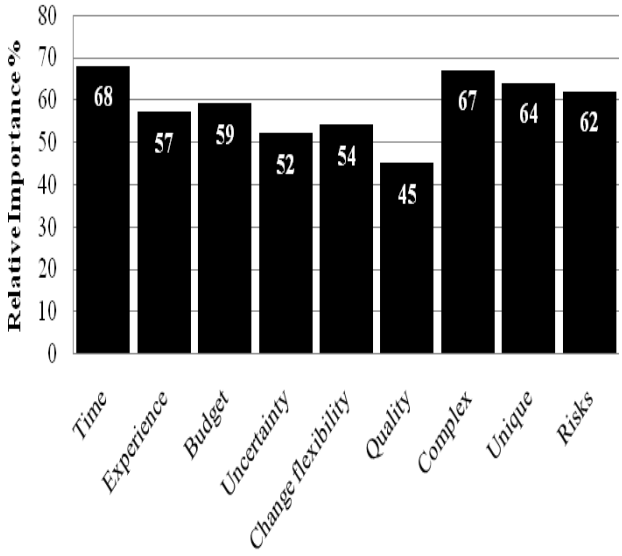

Figure 1 Ranking of Procurement Selection Method Factors by Respondents

indicate that there is no correlation between the factors utilised. However, it has also been shown that practitioners have a high level of willingness to change from traditional procurement to concurrent engineering.

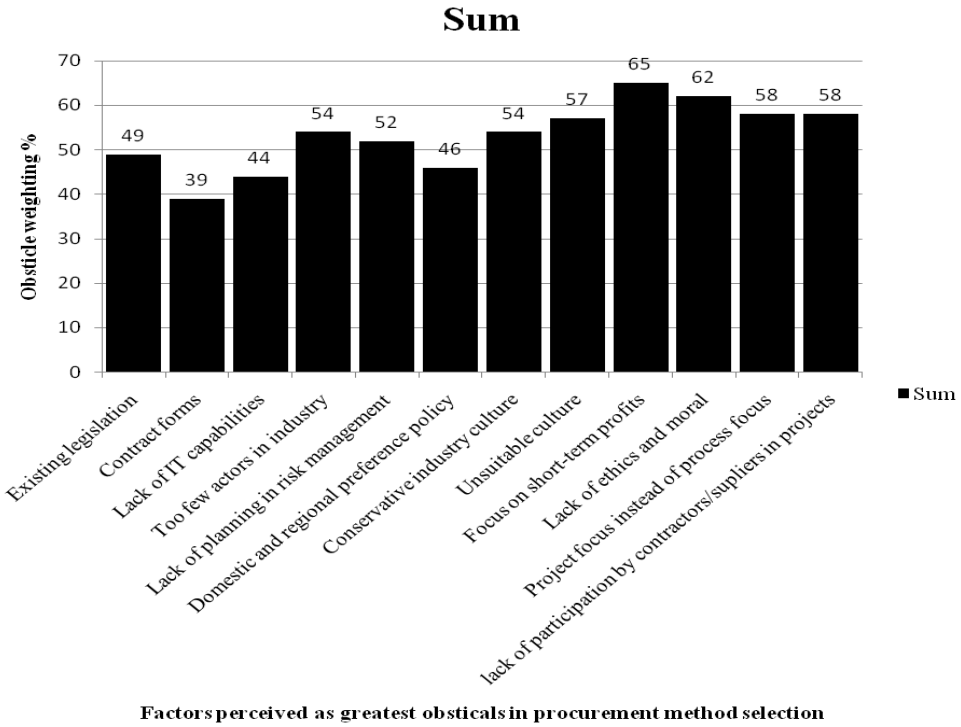

Figure 2: Statistics on Greatest Obstacles to Project Success

It is further demonstrated that procurement practitioners are more familiar with traditional type of procurement refer to Figure 3 below. It can be consummated that not adequate capacity building has taken place to acquaint practitioners to different methods of construction procurement. This has been correlated with the altitude expressed on the degree of familiarity different procurement laws. Most practitioners have indicated allegiance with procurement law of Malawi only (refer to Fig. 4 below). This outlook purports the insignificant level of improvement on the project performance.

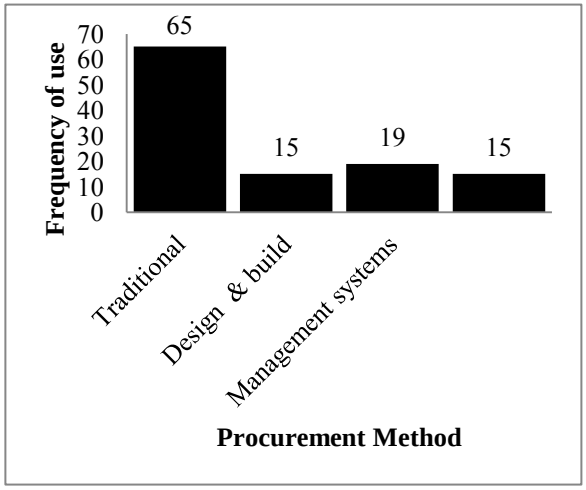

Figure 3: Frequency of Procurement method

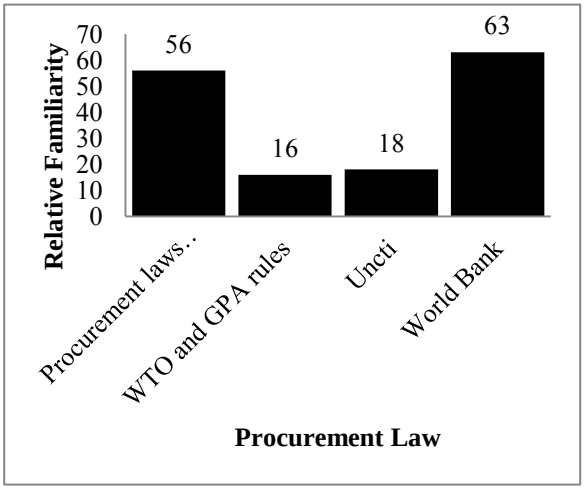

Figure 4: Practitioners' familiarly with procurement law

Hypothesis validation/invalidation

The following were the findings after analysis:

- **Hypothesis No. 1**: That construction time, cost and quality are not significantly affected by organisation setup (culture, lack of project approach and procurers skills).
- **Hypothesis No 2**: That selection factors have an impact on the outcomes of public project. The results under sub hypothesis: "Experience with a procurement method not influencing the project failure" which indicates p value of 0.07 (very close to 0.05), under "Degree of complexity of a project not influencing the project failure" with a p value of 0.029, the sub hypothesis can be rejected. Under "Risk about the project environment not influencing the project failure" with X2 (6) = 15.348 and p value of 0.018 (with 0.05 required) and an r value of 0.4 (moderate correlation), the sub hypotheses can be rejected.
- **Hypothesis No 3**: Procurement guidelines which are brought about by donors

  (sponsors) of construction projects do not significantly affect the project triple bottom project constraints. The results on the null hypothesis are very clear that the null hypothesis can be retained.
- **Hypothesis No.4**: Competition which is advocated by Malawi procurement law rather than cooperation which is now generally globally accepted in the commercial sector as the key to project success significantly affect project

performance. The null hypothesis was rejected i.e. the probability values are ≤ 0.05 and moderate correlations e.g.: Lack of participation by contractors: X2 (6) = 12.507, p = 0.052 = 0.05 (required) and r = 0.4; Lack of information and communication technology capabilities: X2 (12) = 22.351, p = 0.034 ≤ 0.05 and r = 0.5 (required); training of practitioners: X2 (9) = 16.904, p = 0.05 = 0.05 (required) and r = 0.3; lack of information and communication technology capabilities: X2 (12) = 22.351, p = 0.034 ≤ 0.05 and r = 0.5

- **Hypothesis No 5**: That traditional procurement methods being practiced in Malawi and the level of adoption to change do not significantly affect the project performance objectives. This null hypothesis was therefore retained.

CONCLUSIONS AND RECOMMENDATIONS

In terms of weighting of procurement factors, the survey results demonstrate that time, budget, stakeholder involvement were perceived to be of significant importance when selecting a procurement path as they were awarded the highest scores. Complexity, uniqueness and risk follow fourth on the priority list ranked by practitioners. The study deduces that because of the high uncertainty of cost and time associated with construction activities, it is reasonable, logical and convenient for Government to adopt the most familiar type of procurement method for their projects, namely, the traditional procurement approach.

The results also show that the "finished product quality" aspect was not given prominence by a significant number of respondents. This attitude gives further support on why Government has adopted the traditional procurement path that has proved to result in lowest cost contractors being selected almost always. In fact it has been used in Malawi since the colonial era and is likely to remain the preferred choice for the immediate future (Institute of Procurement Managers, Proceedings of Annual Procurement Conference, 2009: 10).

Furthermore the statistical analyses of the responses indicate that the procurement practitioners perceive that they have been adversity affected by the procurement rules by donors. This argument is not validated as to cause project failure. However the basis of the fear needs to be investigated further for all inclusive conclusions to be made. The use of integrative procurement procedures, concerning early involvement of contractors in joint specification (soft parameters) facilitate the establishment of cooperation in client-contractor relationships are supported by the results from the investigation because the results indicate that there is a strong relationship between stakeholder involvement (from the start of a project to completion) to the success thereto. The lack of flexibility in the current procurement law to explore other methods of procurement may have lead to the inherent project failures registered in the last 10 years. With the survey results indicating that the method in procuring works contracts is predominantly traditional (lumpsum), it is clear that lessons need to be drawn especially in connection with the failure rate of construction projects (refer to Fig. 5 below). The analysis indicates that there is consistency with the assumptions (results moderately correlated). There is very strong consensus amongst the practitioners that Malawi needs to change from the status quo and embrace concurrent engineering approach. The case of paradigm shift from the traditional

procurement method to concurrent engineering has been supported by the results of the survey with 42 % of the respondents strongly voting for change to concurrent engineering. The results of hypothesis No. 3 testing have shown that competition which is advocated by the Procurement Law in Malawi is less favoured by the practitioners than the corporation among stakeholders.

ABSTRACT

The performance of the construction industry in Japan has been high but its price competitiveness has been low. Due to rapid change of the industry environment such as social requirement of fair implementation process of public works, however, there is a deep concern that the performance of the industry is being lowered. Many efforts are being made to keep its high performance through enhancing its competitiveness. Comparison between essences of public bidding reforms in Japan and principles of the Best Value Approach shows some ideas on future of public bidding scheme. They are importance of various levels of feedback loops in social capital management and clarification of the position of supervision for appropriate risk sharing between the public client and the vendor. Additionally, in order for local governments with insufficient engineering resources to be truly accountable, it is worthwhile studying alternative evaluation method of proposal and performance including non-technical one.

Keywords**:** best value approach, comprehensive evaluation method, construction industry performance, Japan, public bidding

INTRODUCTION

Recently, the construction industry in Japan is going through major turning points. It is often said that the performance of the industry has been high but its price competitiveness has been low. Due to rapid change of the industry environment such as social requirement of fair implementation process of public works, however, there is a deep concern that the performance of the industry is being lowered. Many efforts are being made to keep its high performance through enhancing its competitiveness.

To realize continuous improvement, it is always useful to study and share theory and practice in other countries. Design and operation of public bidding systems is not exceptional. To discuss what should be strengthened in public bidding reform, this paper focuses on the "Best Value Approach," advocated by Kashiwagi (2010) as a reference of theory and practice in other countries. Since this approach incorporates feeling of "site people" and has much similarity to Japanese schemes, it is expected to give a good hint for a reasonable and realistic solution.

The objective of this paper is, thus, to 1) explain characteristics of the conventional public bidding schemes, 2) overview the reform history of public bidding schemes and the comprehensive evaluation method (CEM), which is to appraise price, technical proposal, and past performance of each bidder, 3) compare the Japanese public bidding reforms with the Best Value Approach, and 4) identify possible areas to be strengthened to achieve the high performance through high competition in the construction industry in Japan which are also applicable to other countries.

CONVENTIONAL PUBLIC BIDDING SCHEME

Designation, "Dango," and the Ceiling Price are characterizing factors of the public bidding systems since the period of high economic growth in Japan. The client first designates trustworthy companies. Dango is complementary and rotational bidding. These designated companies discuss and determine the winner for the project. In some cases the client takes the initiative and authorizes the winner.

This scheme has characteristics. First, quality is ensured. Once the extremely poor work is founded by the client, that vendor would never be designated. Second, transaction costs, particularly the contract monitoring costs and contract enforcement costs are considered low (Watanabe, 2007). Thus, the conventional scheme had been contributing much to smooth implementation of many projects with good quality. Since the price competitiveness is low, however, the construction industry in the conventional scheme is classified in Quadrant III in the Construction Industry Model (Kashiwagi, 2010).

This scheme has a more serious problem than the low price competitiveness. Since the amount of public investment started decreasing, many cases are observed in which dango does not work well. In 1993, one governor and two mayors were arrested for bribery in public biddings. Contractors who desperately wanted projects gave bribe to these politicians and ask them to give "the voice from the heaven" to the other bidders so that they would give up competing. Since then, many dando incidents have been reported. In public bidding during downsizing economy, dango becomes much less successful in Japan. It is needed to develop alternative method to dango that all bidders accept the process and the result of the selection.

REFORMS OF PUBLIC BIDDING IN JAPAN

Overview of reforms

The Japanese government has been making reforms of public bidding. The immediate objective was to enhance fairness of the procedure by improving transparency. In 1993, the Central Council on Construction Contracting Business

worked out the proposal named "Reform of the Bidding and Contracting Procedures for Public Works". In this reform, introduction of the general competitive bidding scheme is determined.

As the designated competitive bidding was replacing the general competitive bidding, however, the anxiety or even fear that quality of construction works may not be ensured in future was growing. There was a great risk that the Japanese construction industry would fall down into Quadrant I from Quadrant III. In 2005, thus, "The act for ensuring the quality of public works" was enacted. The act clarifies fundamental principles and responsibilities of the public client of ensuring quality of public works. The act also states replacement of "competition solely through price" with "comprehensively superior procurement based on price and quality." Here the CEM becomes a key component to procure good quality service with fair and competitive procedure.

Other key components

In addition to the CEM, other key components are refined and developed. The project performance evaluation and CORINS are representative components.

Table 1 shows a prototype of project performance evaluation sheet used by the MLIT. Scores associated with evaluation of "d" and "e" are very low. These high negative scores become important factors preventing execution of extremely poor works.

Table 1: A Prototype of Project Performance Evaluation Sheet

Inspection item		Chief technical evaluation officer					Overall technical evaluation officer					Technical inspector

6. Sociality	I. Regional Contribution						10	5	0							
SUM (=1+2+3+4+5+6)																
Total score (=65+SUM)																

The other component is CORINS (Construction Records Information System) developed by the JACIC (Japan Association of Construction Information Center). This puts the construction record of the public works which contractors register as

"construction records" into the database, and provides it with public organizations. Registration of the public works was started in March, 1994 for those contracts of more than 50 million JPY and was extended to more than 5 million JPY in fiscal year (FY) 2002. As of the end of March, 2010, the number of contractors registered is about 131,000 in total and the number of registered completion construction projects is approximately 3,188,000 in total. This database has been in great use.

INTRODUCTION OF THE CEM

Brief History of the CEM

The CEM has been continuously revised based on results of careful monitoring (Ozawa 2012). Social environment of the CEM is changing. Vendors' strategies to the CEM are also changing. Evaluation items and weight associated with each item are changed in a timely manner based on thorough analysis of results of the CEM.

The CEM in Japan was first applied to two public projects ordered by the former Ministry of Construction in FY 1999. The original objectives of the CEM are to utilize the advanced technology of the private sector, improve the value for money of public investment, and increase the social benefits.

Since application of this type of the CEM needs many preparatory works, however, introduction and utilization of the CEM was very much limited. Thus, "The evaluation method of the performance in the CEM regarding the bidding on construction work" was established in 2002. This method sets the ceiling price at the price of a standard construction method, and giving 100 points as the standard points and 10 points as the additional points. This type of the CEM is positioned as "the standard type CEM." With this direction, the work load of preparation for the CEM was greatly reduced.

In "The Act of promoting quality assurance" enacted in 2005, the role of the CEM is changed to ensuring the quality of public works. Thus, it is required to apply the CEM to projects with small room for technical ingenuity that are ordered by the national and local governments. Here, "The Simple Type" was introduced to comprehensively evaluate the price and the technical capability to ensure the quality of a project with a standard method developed by the client. In addition, "The Proposal of the Advanced Technology Type" was also introduced to solicit advanced technologies which may bring necessary changes in the final product. With "The Simple Type," "The Proposal of the Advanced Technology Type," and "The Standard Type," the CEM is possible to apply to any project with each characteristic such as type of work, scale, and requirement conditions, etc. Now the CEM is applied to more than 99% of projects ordered by the MLIT.

From the second half of fiscal year 2005, price competition became very severe. Extremely low bids frequently occur, and concern of quality deterioration due to poor works has further risen. Thus, "On Emergency Measures to Ensure Quality of Public Works" was summarized in December 2006. As the key measure, the further additional points are introduced of evaluating construction systems. This scheme is called "Verifying Construction Systems Type." Furthermore, in FY 2008 when the serious recession visited, it was required to tale economic measures and to make an early execution of the supplementary budget. To deal with this situation,

an even simpler CEM than "The Simple Type" was applied by emphasizing the past performance of each bidder and skipping submission of a concise construction plan and the interview with engineers.

Effects of the CEM

Table 2 shows how much the CEM has been applied to the projects ordered by the MLIT and the average of the project performance score. The average scores steadily increases as the CEM is applied to more projects.

Table 2: Application and effects of the CEM in projects ordered by the MLIT

FY	The number of applied projects	The ratio of applied projects (%)	Average of Project Performance Score
2005	8,146	16.9	73.2
2006	7,996	76.2	73.7
2007	11,248	97.1	74.2
2008	10,068	98.8	75.0
2009	9,300	99.2	75.6
2010	3,879	99.2	75.5

Note: Evaluation method is modified in FY 2010.

To further study the effects of the CEM, questionnaire survey was conducted by the MLIT in between October 18, 2010 and November 12, 2010. Respondents to this survey are 10 Regional Development Bureaus of the MLIT, etc, 66 local governments, 47 Prefectures, 19 ordinance-designated cities, 414 construction companies, and 716 ordinary people through WEB questionnaires. Two main questions are asked: a) what effect has already appeared or is expected to appear in future and b) requests for improvement of the CEM. Since similar surveys were conducted in 2006, comparison is made to the previous survey. Summary of the results are given in Tables 3 and 4.

Table 3: What effect has already appeared or is expected to appear in future

	MLIT	Local Government	Construction Company	From previous survey
1. Decrease in nonconforming works	✓	✓	✓	up
1) Decrease in the # of accidents				--
2) Completion on time				--
3) Improvement of work performance	✓	✓	✓	--
4) Establishment of quality management systems by the company	✓	✓	✓	--
2. Fairness and Transparency	✓	✓		no change
3. Promotion of competition	✓	✓	✓	down
4. Prevention of dango	✓	✓	✓	no change
5. Expansion of opportunities for participation				no change
6. Improvement of accountability	✓	✓		up
7. Improvement of familiarity with the field		✓		down
8. Utilization of new technology				up

Note 1) ✓ is put in the item where more than half of respondents answer "yes."
Note 2) "—" means that question was not asked in the previous survey.

Both the client and construction company feel that the CEM is effective in "Decrease in nonconforming works," "Promotion of competition," and "Prevention of dango." The both parties also feel that there is still a room for improvement in

the method of evaluating and reviewing technical proposals. As compared with the previous survey, except for the item of "Evaluation and review of technical proposals" a larger ratio of people request for improvement. Although all related parties have been working hard to improve the CEM, this task is still "formidable." To respond to these requests, a major reform is now discussed and implemented.

Table 4: Requests for improvement of the CEM

	MLIT	Local Government	Construction Company	From previous survey
1. Time and cost associated with proceeding the procedure	✓	✓		down
2. Evaluation and review of technical proposals	✓	✓	✓	up
3. Disclosure of the evaluation results			✓	down
4. Cost of developing technical proposals				down
5. Effects preventing low bid		✓	✓	down
6. Consistency between technical proposal and the ceiling price			✓	down
7. Expansion of awarded opportunities for local companies		✓	✓	down

Note: ✓is put in the item where more than half of respondents answer "yes."

COMPARISON BETWEEN THE JAPANESE REFORMS WITH THE BEST VALUE APPROACH

Strength of the scheme in Japan from the viewpoints of the best value approach

Representative principles of the Best Value Approach developed by Kashiwagi are a) Paradigm shift, b) Client should be accountable first, c) Utilization of Past Performance Information, d) Transfer risk to vendors, e) Importance of Pre-Award Meeting and Risk Management, and f) Nontechnical evaluation.

The Act of Public Account in Japan stipulates that general competitive bidding is the due bidding scheme. However, the designated competitive bidding was introduced as an exceptional case, and this scheme has been used as a main bidding scheme for more than 90 years. This demonstrates that the low bid paradigm, that is, "price competition to satisfy detailed specification is the best method," has been uncommon in Japan.

The notion of "Client should be accountable first!" is now widely understood in the construction industry in Japan. A research team was established in 2000 to study how to define the client responsibility and how to fulfil it in infrastructure development and management. This responsibility is defined as "the responsibility of procuring and providing services or goods with good quality in a timely manner at inexpensive price."

Most of the public clients and the private companies have no resistance against using the past performance information. Designation has been made based on the past performance. After the general competitive bidding was introduced instead of the designated one, CORINS was developed. It is now widely used by both the clients and the private companies and become one of the most successful business

models in the construction IT systems. The project performance score also plays a vital role in selecting high performers and supporting the CEM.

Actually the Japanese government is developing and implementing three levels of feedback loops in social capital management in a transparent manner. Minor cycle is the mechanism which can ensure achievement of high quality products from each work. Intermediate cycle is a mechanism which appropriately reflects the past performance of a vendor in the next vendor selection. Major cycle is the mechanism by which experience at each stage of the project life cycle is steadily handed over to its subsequent stage throughout the whole construction production systems and fed back to its upper stream stage. These types of feedback mechanisms are considered essential to keep the performance of construction industry in not only Japan but other countries.

Regarding the risk transfer to the vendor, concept of "responsible construction" has been commonly practiced in Japan. For example, to construct facility truly suitable to the site conditions, it had not been uncommon for a vendor to voluntarily make a minor modification of the design document and execute it. High performing vendors had been willing to take risk and assist the client.

Importance of Pre-Award meeting & Risk Management on site is well discussed. Three parties discussion is recently introduced among the client, consultant, and contractor. To ensure quality, an attempt is made to focus on quality management of each construction process more carefully.

The principle of nontechnical evaluation seems the only major difference between the reform direction headed by the MLIT and the best value approach. The technical evaluation has been possible with high quality in-house engineers and much richer human resources than most of other public client organizations.

Weakness in the Japanese Scheme

However, there is a big concern. In many projects bids concentrate around "the lower limit," and the bid competition substantially becomes price competition. It is becoming more difficult to take a proper balance between the price and non-price part.

Local governments face more risky situations of falling in the low bid paradigm than the MLIT. First, the local government has more direct pressure to be "fair" and "cost efficient" procurement from the local residence. Second, local governments with an insufficient number of engineers are feeling a big hurdle and giving up in introducing the CEM and the evaluation of project performance score, which are practiced by the MLIT. As a result, in more projects, multiple bidders bid at the lower limit and the awarder is determined by tossing a coin. Acceptance of this selection process shows a possibility that governmental officers already fall in believing the low bid paradigm.

The consequent risk to falling in the low bid paradigm is prevalence of the vice circle that existence of poor performers creates poor quality work, which leads to survival of poor performers. Ninomiya (2011) develops and runs a simulation model to represent the survival situation of local companies when the contract

awarder is kept determined by tossing a coin. The simulation results hint a possibility that high performers would be out of business due to hard luck in the long run. These phenomena are also observed in many other countries.

If poorer performers start executing public projects, ambiguous position of supervising scheme in Japan could be a big factor to induce the second risk of the vice circle. The "Action Guidelines for ensuring the quality of public works" states that "The supervisor should not give unnecessary guidance to blur responsibility sharing between the client and vendor or make unnecessary confirmation to lead to cost increase." This inappropriate supervising and risk sharing gives a room for survival of poor performers.

Possible areas to be strengthened

First, inappropriate risk sharing should be avoided through clarifying the position of supervision. Though there is a view that supervision is not needed anymore, its functions of directing design document changes and technical judgment on contract alterations are indispensable in site management. Careful discussion is desirable about the future of the supervising scheme.

Second, it is worthwhile studying how feasible and accountable nontechnical evaluation of proposal and performance of each vendor would be. Actually, the MLIT has ordered one social experimental project to which nontechnical evaluations was applied. In this CEM project, selected bidders' presentations were non-technically evaluated by residential people, and their evaluation results were incorporated into the technical score of each proposal (Kurauchi 2011). In this case the best proposal selected by the client and the residential people happened to be the same. In order for the public client in local governments to be truly accountable, alternative method of proposal and performance evaluation including nontechnical one should be seriously studied.

CONCLUSIONS AND RECOMMENDATIONS

Comparison between essences of public bidding reforms in Japan and principles of the Best Value Approach shows some ideas on future of public bidding scheme. One of Japan's strength, various levels of feedback loops in social capital management, is considered essential in maintaining and improving the performance of construction industry. The position of supervision should be clarified to always realize appropriate risk sharing between the public client and the vendor. In order for local governments with insufficient engineering resources to be truly accountable, it is worthwhile studying alternative evaluation method of proposal and performance including non-technical one.

UNIQUENESS OF PIPS/PIRMS MODEL

Jacob Kashiwagi[1]

[1]*Performance Based Studies Research Group (PBSRG), Arizona State University, PO Box 870204, Tempe, AZ 85287-0204, USA*

ABSTRACT

Although some reports have shown the performance of the construction industry to be improving, it has yet to find a solution to ensure high performance on construction projects and services. Over the last 18 years, many public organizations have tested a revolutionary model created out of Arizona State University, called the Performance Information Procurement System / Performance Information Risk Management System. The test results have indicated that the model has the ability to ensure high performance on construction projects. This paper presents results of a literature review performed by a doctorial candidate, identifying different characteristics of the PIPS/PIRMS model from traditional management models. These characteristics could show why the PIPS/PIRMS model has been able to sustain performance while traditional models have fallen short.

Keywords: management, measurement, performance, procurement.

INTRODUCTION

In 1994, a landmark study was published by Sir Michael Latham identifying the continued failings of the construction industry in the UK (Cahill et. al., 1994). Latham's report was able to bring to the fore front many industry problems that had been identified for the last 30 years. Latham identified many of the current business practices as the reason for the adversarial environment, inefficiency, and low performance of projects. The report caught the attention of many buyers and suppliers in the construction industry and was the motivating factor in many industry initiatives in the late 1990's. However, after seven years, of industry reform and initiatives to boost performance, buyers and suppliers still were not satisfied with the performance of construction services. In 1997, the UK commissioned a task force headed by John Egan to perform another study to identify solutions to the industry's problems, this time approaching the situation from the buyer's perspective. The study identified a need for more leadership and integrated processes and teams. The Egan report (1998), like the Latham report, initiated many efforts to try and improve the performance of the industry. Despite the efforts initiated by the Latham and Egan reports, the performance of construction did not improve in the early 2000's and the industry has only recently seen slight improvement in certain areas of the industry. In fact, in many areas the performance of the industry has decreased. Overall efficiency and

[1] jacob.kashiwagi@asu.edu

productivity of construction has struggled in the last decade (Georgy, 2005; Bernstein, 2003). Studies performed in the United States like those in the UK have shown suboptimal performance and low customer satisfaction in the construction industry (Adrian, 2001; Cahill and Puybaraud, 1994; CFMA, 2006; Chan, 2004; Chan, 2004; Davis et. al., 2009a; Davis et. al., 2009b; Egan, 1998; Flores and Chase, 2005; Hamel, 2007; Lepatner, 2007; Simonson, 2006; Post, 2000). The low performance have also given rise to disputes, claims, and litigation, creating even greater obstacles to improving industry performance (Childs, 2010; Doree, 2004; Glancy, 2008; Langlinais, 2011; Rijt, et. al., 2009; Wearden, 2008; Egan, 1998).

The most recent KPI report out of the UK has shown construction performance to be improving from 2000 to 2011 (Industry Performance Report 2011):

1. Overall Customer Satisfaction increased from 63% to 80%.
2. Projects completing on time rose from 28% to 45%.
3. Projects completing on budget rose from 50% to 63%.

However, despite the increases in performance from 2000, the construction industry still has room to improve. With only 45% of projects completing on time and 63% completing on budget, this is far from a high performing industry. The UK industry report also showed that the performances of construction services are still struggling with increasing their efficiency (Industry Performance Report 2011):

1. Contractor Satisfaction with client provision of information remained at 69% from 2010. This KPI increased only 5% from the initial measurement in 2003.
2. Contractor Profitability declined to 5% from 7.7% in 2010.
3. The clients rating of the amount of defects on projects declined to 68% from 75% in 2010. The client rating on defects on a project is only 3% higher than the initial client rating in 2000 (65%)

The declining profitability of construction companies and the amount of defects on projects show that the industry has not yet stabilized their performance. Although, the industry in some cases have seen improvements in performance and customer satisfaction over the last decade, the industry has yet to develop process that allows it to consistently deliver construction services efficiently (Adrian, 2001; Cahill and Puybaraud, 1994; CFMA, 2006; Chan, 2004; Chan, 2004; Davis et. al., 2009a; Davis et. al., 2009b; Egan, 1998; Flores and Chase, 2005; Hamel, 2007; Lepatner, 2007; Simonson, 2006; Post, 2000).

PERFORMANCE INFORMATION PROCUREMENT SYSTEM / PERFORMANCE INFORMATION RISK MANAGEMENT SYSTEM

The Performance Information Procurement System / Performance information Risk Management Process (PIPS/PIRMS), was developed by Dr. Dean Kashiwagi, out of Arizona State University (Kashiwagi, 2012). PIPS/PIRMS was another solution to try and improve the construction industry's inefficiency and low performance. With its unique management philosophy and technology it claimed to be able to minimize all of the current problems the construction industry was facing. After being tested over

the last 18 years, the process has shown it has the capability to deliver high performing construction work and services (PBSRG, 2012):

1. Over 1000 tests and $12M of industry funding to conduct the tests.
2. Delivering of $4.4B of services.
3. Copyrighted and licensed to 26 different research clients (most licensed technology developed at Arizona State University (ASU)
4. The Dutch Ministry of Transportation received the Dutch Sourcing Award for 2012, due to its implementation of PIPS/PIRMS on their $1B fast track infrastructure projects.
5. Tested all over the world (Botswana, Netherlands, Malaysia)
6. Vendors increased their profit margin by 5%. (State of Hawaii report, 2002; University of Minnesota Report, 2011).
7. Minimize management transactions by as much as 90%.
8. 50% of the time the awarded best value is the lowest cost.
9. Customer satisfaction is at 98%.

A CIB Task Group (TG61) performed a worldwide study identifying innovative construction methods with documented high performance results. The study filtered through more than 15 million articles and reviewed more than 4,500 articles. In the end the study found only 16 articles with documented performance results. PIPS/PIRMS was one of three construction methods found in those articles, and it was found in 75% (12 of 16) of the articles (Sullivan, et. al., 2008).

PIPS/PIRMS Process

PIPS/PIRMS has three phases (Figure 1). The phases are selection, clarification of proposal, and the award of contract and risk mitigation.

Phase 1 is identified as the PIPS. It is a best value selection process that identifies the best value supplier through a series of five filters (Figure 2):

1. Past Performance Information - The suppliers must show satisfaction rating of services performed for past clients.
2. Project Capability - The suppliers are required to submit three documents (project capability, risk assessment, and value added) that will be evaluated by the buyer's selection committee. The three documents must show how the supplier can deliver a high performing project through their experience and expertise, ability to foresee and mitigate risk, and ability to add value to the project.
3. Interview - The supplier's core team that will be assigned to the service will be questioned by the buyer's selection committee. The focus of the questioning will be to identify the team's ability to mitigate risk.
4. Prioritization - Through a weighting system and a linear model the suppliers are ranked on their ability to deliver value.
5. Dominance Check - The buyer checks all information on the highest prioritized supplier, including their cost, to ensure there is no information that would cause the buyer to select a different supplier.

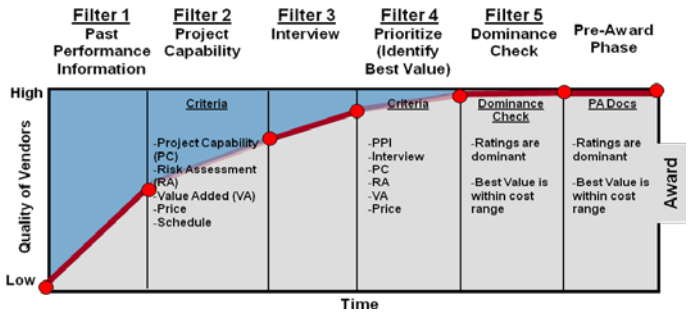

Figure 2: PIPS Filters

After Filter 5 only one supplier moves into the Clarification Phase (Phase II). Phase II and III is considered the PIRMS. During Phase II the supplier will finalize the contract, pre-plan the entire project, and finally obtain contract award. In Phase III the supplier will be expected to track all deviations that occur throughout the length of the service/project. Phase II has been identified as the most critical of the steps for ensuring high performance and customer satisfaction on a project/service. The success of the system was derived from the leadership concepts built into its management model. Research has verified that buyers did not need to run the PIPS to achieve high performance results on their projects, but the PIRMS was enough to ensure project success (Kashiwagi, J. et. al., 2009; Kashiwagi D. et. al., 2010).

HYPOTHESIS AND METHODOLOGY

The author proposes that the PIPS/PIRMS process has unique management/leadership traits that allow it to deliver high performing construction projects and services. If identified these traits could not only improve other construction methods and processes, but also management and delivery processes in other industries. To identify the unique management/leadership traits in PIPS/PIRMS the author performed a literature research that compared the PIPS/PIRMS model to other management systems in the construction industry. A "management system" defined as, any model describing how a buyer interacts with one or more suppliers in the construction industry. Information for the comparison was derived through a literature research (Kashiwagi, 2012).

PIPS/PIRMS COMPARISON LITERATURE RESEARCH

The following steps were taken to complete the literature research:

1. A search for all management systems
2. Identifying traits found in the identified management systems
3. Identifying traits found in the PIPS/PIRMS system
4. Analysis between PIPS/PIRMS traits and all other construction management system traits

Literature Search Process

To ensure that the search was organized and effective in identifying all available documented information on construction management systems the following procedure was setup and followed: 1. Keyword and database searching, 2. Searching

and filtering through literature, 3. Documentation of Information. The author wanted to keep the searches as broad as possible to minimize the chances of missing any management systems, thus the author used main scientific areas as search terms with "construction" in front of each term: Project Management, Risk Management, Supply Chain Management, Outsourcing, Quality Assurance, Quality Control, Performance Information, Purchasing, Contract Management. These keywords were used and searched in both academic and non-academic search engines to ensure that as much relevant information on construction management systems could be found. The main search engines that were used include: EI Compendex, Emerald Journals, ABI/Inform, and Google Scholar.

Table 1: Key Word Search Log

Search results are shown in Table 1. To identify relevant articles from the search results, the author read the abstracts of each article to see if a construction management system was discussed. The author found 55 papers that were relevant to the research. After exhausting the previously mentioned resources, an in depth search was conducted in order to locate the relevant articles that were identified as references in the articles returned by the search engines. Only articles that were published after 2005 were searched for. To find the referenced articles, the same four search engines were employed. This search also utilized several other search engines as well. The other search engines used included Illiad interlibrary service, ProQuest, ScienceDirect, ASCE Library, and Informaworld. The author found an additional 32 relevant papers from this method of research.

Information on the PIPS/PIRMS was collected from the following different types of publications: Books, Journal and Conference Publications, Government Reviews on the PIPS/PIRMS process. The Performance Based Studies Research Group has a database of all published works that have been written on the PIPS/PIRMS process, which was used to find all publications.

Construction Management Model Traits

The literature search found over 100 different management systems. The author reviewed each system and identified characteristics of each system. The author then categorized the characteristics of each system into 36 major traits (Kashiwagi, 2012):

1. Pre-planning
2. Communication
3. Collaboration and partnering
4. Shared accountability
5. Trust
6. Multi-Disciplinary Team
7. Early Supplier Involvement
8. Top Management Support
9. Contract Terms
10. Long-term contracts/relationships

11. Defining roles of key project individuals
12. Living Scope (allows scope to be molded throughout service/project life)
13. Scope of Service
14. Incentives and Penalties
15. Collecting information on project to make decisions
16. Measurement tools
17. Insurance and bonds
18. Document Structure
19. Training
20. Stakeholder Management
21. Delegate Responsibility
22. Knowledge Management System
23. Inspection
24. Buyer Decision Making
25. Buyer Performance Evaluation (buyer identifies if supplier is performing)
26. Third Party Certification
27. Risk Sharing
28. Identify Project Constraint
29. Technical Risk Mitigation
30. Computer Analysis
31. Simulation Technology
32. Buyer/Supplier IT system integration
33. Master Supplier (1 supplier takes care of entire project)
34. Hire experienced PM/ /facilitator/integrator
35. Hire a quality surveyor
36. Information Technology (IT system)

The frequency of each trait found in the articles is represented in the Figure 3. The numbers on horizontal axis correlate with the trait number found above. Traits 2 and 3 (Communication and Collaboration) being the traits that were most frequently referenced. The closest trait to the top two was Trait 16 (which was measurement).

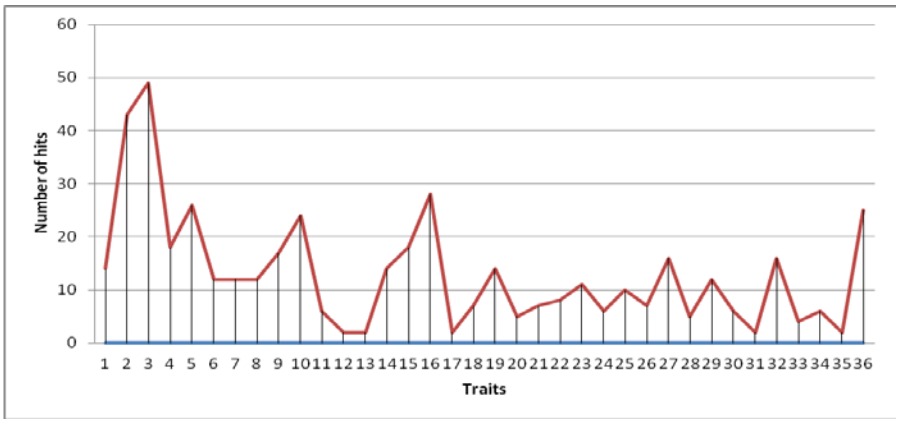

Figure 3: Trait Frequency Graph of Articles

PIPS/PIRMS Traits

After reviewing the literature on the PIPS/PIRMS the following 14 traits were found (Kashiwagi, 2012):

1. No-influence, no-control, no management philosophy
2. Seamless contract
3. Supplier contract creation
4. Require a plan
5. Problem Contracting
6. Communication Minimization
7. Expert Supplier Model
8. Dominant Information
9. Pre-planning

10. Senior/Top Management Support
11. Measurement Tools
12. Training Program
13. Stakeholder Management
14. Information Communication Technology

The PIPS/PIRMS traits were documented the same as the other construction management models (Kashiwagi, 2012).

Analysis Between PIPS/PIRMS and Construction Management Systems
After comparing the traits found in the construction management systems with those found in the PIPS/PIRMS, it was found that PIPS/PIRMS had six traits that were also found in the construction management systems, and 8 unique traits that could not be found in any other construction management system, which were as follows:

1. No-Influence, No Control, No Management philosophy - The client releases all control mechanisms (i.e. rules, requirements, oversight, etc.) and minimizes management of the supplier
2. Seamless Contract - Contract is used to mitigate risk instead of being a legal/regulatory/control document.
3. Supplier Contract Creation - The supplier creates the contract
4. Require a plan - The supplier is required to have a detailed plan and relay that plan to the client before a contract is signed.
5. Problem Contracting - System does not require the buyer to identify the scope of the project. The supplier creates the scope of the contract and the buyer approves it, before contract signing.
6. Communication Minimization - System tries to minimize all communication.
7. Expert Supplier Model - System assumes supplier has no technical risk and focuses on mitigating risk the supplier does not control.
8. Dominant Information - System tries to minimize decision making of all parties through simplification and presenting information that is interpreted the same by all parties.

In comparing the traits, some of the major observations that were found regarding the difference between the PIPS/PIRMS process and construction management systems were:

1. Many of the construction management traits were directly opposed to the "No-Management" philosophy of PIPS/PIRMS.
2. No other model required the supplier to have a plan before contract signing, mitigate risk they did not control, and use the contract as the mechanism to protect the supplier and minimize risk for the buyer.
3. No other model focuses on eliminating the sharing of technical details with the client, and forces all information to be dominant (i.e. simple, clear, succinct, etc.)

The closest traits to the PIPS/PIRMS that the construction systems identified were:

1. The act of trying to minimize problems and inefficiencies through pre-planning.
2. The industry found that measurement is vital to project success. The development of measurement tools and structures that measure the suppliers is an important movement. Unfortunately, the industry has found it difficult to find measurement systems that can truly differentiate the performance of suppliers and takes minimal effort to maintain.

CONCLUSIONS

The construction industry is in need of a process that can consistently deliver high performing and efficient projects/services. The PIPS/PIRMS model has documented high performance results from 18 years of testing. One of the reasons for its success is due to its unique leadership traits that have built its management system. It was proposed that identifying the unique management traits of PIPS/PIRMS could help to improve the construction industry's performance and efficiency. This paper reviewed a literature research that was performed to identify the unique traits of the PIPS/PIRMS management system compared to other construction management systems. The research found that out of 44 management traits identified the PIPS/PIRMS had eight unique traits that were not found in any other management systems. Identifying that some of the reasons why PIPS/PIRMS is successful could be due to:

1. The client releases all control mechanisms (i.e. rules, requirements, oversight, etc.) and minimizes management of the supplier.
2. Forcing the supplier have a plan and be capable of relaying that plan to the buyer before the contract is awarded.
3. The buyer holds the supplier accountable by forcing them to identify the scope of work, create the contract, measure their performance, mitigate risk they do not control, and relay all project information in dominant or clear and easy to understand terms.

The author proposes that with further testing and research the PIPS/PIRMS model could revolutionize construction management systems and drastically improve construction performance and efficiency.

Utilising partnering to improve business outcomes in Housing Associations`

David Liguori[1], Prof James Sommerville[2] and Dr David Manase[3]

[1,2,3] *School of Engineering and the Built Environment, Glasgow Caledonian University, Glasgow, G4 0BA, United Kingdom*

ABSTRACT

Nearly 15 years ago, an industry changing report entitled "Rethinking Construction" was published. The purpose was improving the performance of the UK construction industry. The report outlined specific targets for improvement that were considered achievable through the implementation of certain processes. The report advocated partnering as the procurement method that could achieve the targets for improvement and identified the social housing sector as potential beneficiaries of this procurement model. Housing Associations are facing challenging economic conditions that may induce a reversion to lowest price traditional procurement. A review of these targets for improvement in terms of importance and perceived success through utilising partnering could ultimately provide more confidence to Housing Associations that perseverance with partnering could assist long-term value for money. A quantitative research methodology was adopted for Housing Associations to numerically rate the targets for improvement, in terms of importance and perceived success. The research concluded that the most important and potentially successful target for improvement achieved through partnering, considered by Housing Associations, was reduction in defects. The findings create an understanding of the current priorities of project deliverables for Housing Associations and also assess the perceived likelihood of achieving the targets for improvement through the utilisation of partnering.

Keywords: Housing Associations, partnering, procurement, targets for improvement

INTRODUCTION

An important publication that evoked change within the construction industry was entitled "Rethinking Construction", produced by Sir John Egan. The report identified specific practices which could be incorporated within the United Kingdom (UK) construction industry, which included a customer focus, collaborative team working and a quality driven agenda. Egan (1998) advocated the divergence of the UK construction industry away from the traditional fragmented philosophies to a focus on a collaborative working ethos, which can be translated through partnering. Egan (1998) believed that this basic transition of culture and structure within the UK construction industry was necessary if the benefits of partnering were to be achieved.

[1] David.liguori@gcu.ac.uk
[2] J.sommerville@gcu.ac.uk
[3] David.manase@gcu.ac.uk

In an attempt to justify the cultural change within the construction industry, moving towards the use of partnering, specific targets for improvement were set by Egan (1998). The targets included: capital cost reduction by 10%; construction time reduction by 10%; predictability increase by 20%; defects reduction by 20%; accident reduction by 20%; productivity increase by 10%; and turnover and profits increase by 10%. The UK social housing building sector was specifically identified as a potential beneficiary of the partnering ideology. Egan compliance measures were introduced by the Housing Forum (2002), which specified the utilisation of Key Performance Indicators (KPIs) and a commitment to partnering.

The subsequent report was published in 2002 entitled "Accelerating Change" and was the follow-up to assess the progress made since "Rethinking Construction" in 1998. Egan (2002) highlighted that the targets for improvement were being achieved and exceeded through measuring demonstration projects. The perceived benefits of partnering such as: effective cost control (Pheng, 1999); effective time control (Black et al., 2000); and improved quality (Brown, 1994) appeared to be justified upon publishing the results of the demonstration projects researched by Egan (2002). Consequently, Housing Associations in the UK have been encouraged for to utilise partnering agreements as the preferred procurement method for delivering construction and maintenance projects. The Housing Forum (2002) encouraged Housing Association clients to embrace partnering via long term strategic supply chain alliances. Fortune and Setiawan (2005) noted that Housing Associations involved in the delivery of new socially owned rented housing schemes have been lobbied indirectly through the widespread promotion of the recommendations by Egan, to adopt partnering agreements in improving the performance of projects.

An important consideration associated with the positive results detailed within the Accelerating Change publication and the continual endorsements for Housing Associations to utilise partnering is the chronological timeline of economic conditions within the last 10 years. These endorsements were vociferous during an economic period of prosperity, with ease of funding and investment into the construction industry. Currently, construction industries worldwide are facing unprecedented difficulties due to the reduction of available funding. These challenging conditions are also being faced by Housing Associations, with Gibb and Leishman (2011) emphasising the reduced funding available for new build social housing. The former Housing Minister in the Scottish Parliament, Alex Neil Scottish Government (2010), also highlighted to Housing Associations, that achieving value for money was an essential element to underpin the Scottish Government`s future investment programme in housing. This could tempt Housing Associations to revert back to traditional lowest price procurement in an attempt to drive prices down. Strongly opposing this strategy, Sir Michael Latham (2008) emphasised that if clients abandon best practice, close down frameworks, stop partnering, and return to lump-sum, single-tender contracts, based solely on lowest price, the industry will go back to its undesirable practices. It is therefore important to understand the importance placed by Housing Associations on the targets for improvement outlined by Egan (1998) nearly 15 years ago. This will identify Housing Associations priorities during the challenging economic conditions that have induced some clients to position low costs as the primary objective. Evaluating if Housing Associations believe that the targets for improvement can be achieved through adopting partnering during this economic climate may provide an understanding of the Housing Association perception of partnering and establish if a reversion to traditional lowest price tenders is likely.

METHODOLOGY

An initial critical analysis of literature was conducted to assess the key targets for improvement outlined by Egan (1998) and the corresponding results published four years later (Egan, 2002). Of the seven targets, five were selected for the research as they are more relevant to Housing Associations. These were capital cost reduction, construction time reduction, predictability increase, defects reduction and accident reduction. A quantitative research methodology was selected to identify the level of importance placed on these key targets for improvement and the perceived success from an exclusive Housing Association perspective. A questionnaire was compiled and distributed to Housing Association procurement personnel. This questionnaire was produced for respondents to rate their opinion on the level of importance associated with specific key targets for improvement and the levels of agreement for achieving the targets from adopting partnering. The Likert scale method was adopted for Housing Associations to rate the level of importance with the scale represented by 1 = very unimportant, 2 = not important, 3 = neither important nor unimportant, 4 = important, 5 = very important. The Likert scale method was also utilised for Housing Associations to rate the level of agreement that the key targets for improvement can be achieved through adopting partnering during the current economic conditions. The scale was represented by 1 = strongly disagree, 2 = disagree, 3 = agree, 4 = strongly agree. The survey sample was compiled by utilising the Scottish Federation of Housing Associations information on the current Housing Associations operating in Scotland. The investigation enabled the identification of 90 Housing Associations in Scotland that possessed the capabilities of answering the questionnaire. From the 90 surveys distributed, 52 responses were received, providing a response rate of 58%.

KEY TARGETS FOR IMPROVEMENT

Capital cost reduction

The analysis of the quantitative data identified that 35 of the 52 Housing Associations (67%) considered capital cost reduction as either important or very important. The disseminated ratio of the 35 can be split between 25 as “important” and 10 indicating “very important”. Of the 52 Housing Associations, 8 (15%) placed neither importance nor unimportance on capital cost reduction. The data highlighted that 8 of the 52 Housing Associations (15%) considered capital cost reduction as “not important”. There was 1 Housing Association (2%) that considered cost reduction “very unimportant” The calculated mean level of importance placed by Housing Associations for capital cost reduction was 3.673. “Important” is represented by 4, therefore the mean response would be converted to 4 by rounding up to the nearest whole number. The mode is also 4, representing that “important” was the most frequently used response by Housing Associations. A maximum range of 4 was calculated as results ranged from 1 “very unimportant” to 5 “very important”.

When considering the level of agreement placed by Housing Associations on capital cost reduction being achieved through partnering, 31 of the 52 Housing Associations (59%) considered this achievable. 24 Housing Associations “agreed” and 7 Housing Associations “strongly agreed”. Of the 52 Housing Associations, 16 (31%) “disagreed” highlighting that they do not believe that 10% capital cost reductions can be achieved through partnering. The data indicated that 5 of the 52 Housing Associations (10%) “strongly disagreed” that adopting partnering would achieve the target construction cost reduction. The calculated mean level of agreement placed by Housing Associations was 2.635. As “agree” is represented by 3 the mean response

would be converted to 3. The mode is 3, representing that "agree" was the most frequently used response by Housing Associations.

Construction time reduction

When considering the level of importance placed by Housing Associations on construction time reduction, 22 of the 52 Housing Associations (43%) considered this as either important or very important. This translates into a split of 16 Housing Associations considering the target as being "important" and 6 rating as "very important". Of the 52 Housing Associations, 18 (35%) placed neither importance nor unimportance on construction time reduction. The results indicated that 9 of the 52 Housing Associations (17%) considered construction time reduction as "not important". The data highlighted that 3 of the Housing Associations believed this target for improvement was "very unimportant". For construction time reduction, the calculated mean level of importance placed by Housing Associations was 3.250. As "neither important nor unimportant" is represented by 3 the mean response would be converted to 3. The mode is 3, representing that "neither important nor unimportant" was the most frequently used response by Housing Associations. Similarly to capital cost reduction, a maximum range of 4 was calculated.

The data revealed that only 30 of the 52 Housing Associations (58%) agreed that the construction time reduction target for improvement could be achieved through partnering. Of these 22 Housing Associations, 25 "agreed" and 5 "strongly agreed". Of the 52 Housing Associations, 15 (29%) "disagreed" highlighting that they do not believe that 10% capital cost reductions can be achieved through partnering. 7 Housing Associations (13%) "strongly disagreed" with achieving this target. The calculated mean level of agreement placed by Housing Associations was 2.538. As "agree" is represented by 3 the mean response would be converted to 3. The mode is 3, representing that "agree" was the most frequently used response.

Cost/Time Predictability increase

The data identified that 40 of the 52 Housing Associations (78%) believed that cost/time predictability increase was either important or very important. The 40 can be split between 28 as "important" and 12 indicating "very important". Of the 52 Housing Associations, 5 (10%) placed neither importance nor unimportance on cost/time predictability increase. There were 7 Housing Associations of the 52 (13%) that considered cost/time predictability as "not important". The mean level of importance placed by Housing Associations for this target for improvement was 3.865. "Important" is represented by 4, therefore the mean response would be converted to 4 by rounding up. The mode was 4, representing that "important" was the most frequently used response by Housing Associations. The calculated range of 3 was lower as none of the Housing Associations considered predictability increase as "very unimportant".

Cost/time predictability increase by 20% was a target that generally, Housing Associations considered achievable through adopting partnering as 39 of the 52 (75%) rated this target either "agree" of "strongly agree". 20 of the Housing Associations rated "agree" with a further 19 rating "strongly agreed". Of the 52 Housing Associations, 10 (19%) "disagreed" highlighting that they do not believe that 20% increase in cost/time predictability can be achieved through partnering. There were 3 Housing Associations (6%) that "strongly disagreed" that this target could be

 ISBN: 978-1-84219-840-7 .

achieved. The mean level of agreement was calculated at 3.058, with a mode of 3, therefore represents “agree”.

Reduction in defects

Housing Associations appear to place significant importance on reducing defects as 43 of the 52 Housing Associations (83%) considered this as either important or very important. This translates into a split of 27 Housing Associations considering the target as being “important” and 16 rating as “very important”. Of the 52 Housing Associations, 5 (10%) placed neither importance nor unimportance on construction time reduction. Only 4 of the 52 Housing Associations (8%) considered reduction in defects as “not important”, with none of the respondents regarding this target for improvement as “very unimportant”. The calculated mean level of importance placed by Housing Associations was 4.058. As “important” is represented by 4 the mean response would be rounded down to 4. The mode is 4, representing that “important” was the most frequently used response by Housing Associations. Similarly to predictability increase, a range of 3 was calculated.

When considering the level of agreement placed by Housing Associations on reduction in defects being achieved through partnering, a significant 46 of the 52 Housing Associations (88%) considered this achievable. 13 Housing Associations “agreed” and 33 Housing Associations “strongly agreed”. Of the 52 Housing Associations, 6 (12%) “disagreed” highlighting that they do not believe that 20% reduction in defects can be achieved through partnering. None of the 52 Housing Associations “strongly disagreed” that adopting partnering would achieve the target reduction in defects. The calculated mean level of agreement placed by Housing Associations was 3.519. As “strongly agree” is represented by 4 the mean response would be rounded up to 4. The mode is 4, representing that “strongly agree” was the most frequently used response by Housing Associations.

Reduction in accidents

The results identified that 26 of the 52 Housing Associations (50%) considered reduction in accidents as either important or very important. The 26 can be split between 14 as “important” and 12 indicating “very important”. There were 17 Housing Associations (33%) that placed neither importance nor unimportance on reduction in accidents. Of the 52 Housing Associations, 9 (17%) considered this target for improvement as “not important”. The mean level of importance placed by Housing Associations was 3.558. Similarly to predictability increase and reduction in defects, none of the Housing Associations consider reduction in accidents as “very unimportant”. As “Important” is represented by 4, the mean response would be converted to 4 by rounding up. The mode was 3, as “neither important nor unimportant” was the most frequently used response by Housing Associations. Reduction in accidents had a range of 3 as none of the Housing Associations considered this target as “very unimportant”.

Reduction in accidents by 20% was a target that 30 of the 52 Housing Associations considered achievable through adopting partnering. 22 of the Housing Associations rated “agree” with a further 8 rating “strongly agreed”. Of the 52 Housing Associations, 19 (37%) “disagreed” highlighting that they do not believe that 20% reduction in accidents can be achieved through partnering. There were 3 Housing Associations (6%) that “strongly disagreed” that this target could be achieved. The mean level of agreement was 2.673, with a mode of 3, therefore represents “agree”.

DISCUSSION

The research identifies the important targets and perceived success achievable through implementing partnering from a Housing Association perspective. The most important target for improvement considered by Housing Associations was reduction in defects by 20%, with a mean rating of 4.058. The second most important target was cost/time predictability increase by 20%, which scored a mean of 3.865, followed by capital cost reduction by 10% with a mean rating of 3.673. The two least important targets were reduction in accidents by 20%, with a mean rating of 3.558 and construction time reduction by 10%, which was scored a mean of 3.250. The most agreed with target that can be achieved from partnering, considered by Housing Associations was also reduction in defects with a mean rating of 3.519. The second most likely target to be achieved was cost/time predictability increase with a mean of 3.058. The third was reduction in accidents with a mean rating of 2.673, followed by capital cost reduction, which scored a mean of 2.635. The least agreed with target that can be achieved through partnering from a Housing Association perspective was construction time reduction with a mean of 2.538. Table 1 illustrates the results.

Table 1 – Synopsis of results

HOUSING ASSOCIATION IMPORTANCE LEVEL			
Target for improvement	**Mean**	**Mode**	**Rank**
Reduction in defects by 20%	4.058	4	**1**
Cost/time predictability increase by 20%	3.865	4	**2**
Capital cost reduction by 10%	3.673	4	**3**
Reduction in accidents by 20%	3.558	3	**4**
Construction time reduction by 10%	3.250	3	**5**
HOUSING ASSOCIATION LEVEL OF AGREEMENT			
Reduction in defects by 20%	3.519	4	**1**
Cost/time predictability increase by 20%	3.058	3	**2**
Reduction in accidents by 20%	2.673	3	**3**
Capital cost reduction by 10%	2.635	3	**4**
Construction time reduction by 10%	2.538	3	**5**

Unsurprisingly, Housing Associations place significant importance on reduction in defects. A primary factor could be maintaining tenant satisfaction that is measured through key performance indicators by Housing Associations. The results support Jones and O`Brien (2003) who highlighted the importance of tenant satisfaction for Registered Social Landlords (RSLs). Cost/time predictability increase is another importantly viewed target for Housing Associations. This could be attributed to the strict monitoring of budgets by housing Associations, not only for new build development, but also planned maintenance cycles. The importance level placed by Housing Associations on capital cost reductions was unanticipated, as a reasonable assumption would be that this target could have been the top priority due to the reduced grants and investment available for Housing Associations (Gibb and Leishman, 2011). There was still a substantial degree of importance placed capital cost reduction, acknowledging the need to make savings. Reductions in accidents and construction time were considered the least important targets for improvement by

Housing Associations. Quality and cost appear to be the main priorities for Housing Associations in the challenging economic conditions.

Housing Associations perception of the primary target that can be achieved through adopting partnering was conclusively reduction in defects. This supports Egan (2002) who believed that the ethos of partnering facilitates the development of quality consciousness. Housing Associations also appear to consider that cost and time predictability is more likely to be achieved through partnering than actual capital cost reductions or reducing the construction time. The Housing Association perception echoes Loraine and Williams (2000), who advocated that partnering provides increased certainty of out-turn cost and time. Housing Associations did not strongly agree that reductions in accidents, capital cost and construction time could be achieved through adopting partnering. 41% of Housing Associations disagreed that partnering could result in capital cost reductions. This perception challenges Cowan *et al*., (1992) who highlighted cost savings could be made through partnering. 42% of Housing Associations did not believe that partnering produce reductions in construction time, which contradicts the belief of Black et al., (2000) that partnering can reduce construction time as a result of better schedule performance. A reduction in accidents was not considered to be achievable through adopting partnering by 43% of Housing Associations. This challenges Chan et al., (2003), who suggested that collective responsibility of partnering can reduce the risk of hazardous working.

CONCLUSION

The three main priority targets for improvement for Housing Associations is reduction in defects, cost/time predictability increase and capital cost reductions. The reduction in defects is unsurprising, given the necessity for high levels of tenant satisfaction to be achieved through improved quality. Interestingly, Housing Associations place more importance on cost/time predictability increase than actual capital cost reductions. This was unanticipated as a reasonable assumption was that a consequence of the reduction in investment and funding could have resulted in an overwhelming need for capital costs to be reduced. There appears to be a degree of cynicism by Housing Associations as approximately a third of responses disagree that adopting partnering will not result in the achievement of the targets for improvement. Housing Associations priority of reduction in defects and the strong perception that this can be achieved through partnering could result in perseverance with the endorsed use of partnering. However, with a third of Housing Associations disagreeing with the notion of achieving the targets for improvement through partnering, a reversion to traditional procurement is possible.

Abstract:
The construction industry forms a significant component of most economies and is responsible for a large share of revenue generation and employment creation. However, this very important industry suffers from a negative image as it has been characterised by a relatively low-status with unyielding and uncompromising working conditions hardly offering any job security. Regardless of these perceptions of construction, it is still characterised by a persistent culture of white male-dominance. The negative image of being identified with stereotyped white male values is said to adversely affect recruitment of minority groups to the industry notwithstanding that the white population is aging. As a result, Black and Minority Ethnics (BMEs) are proportionally underrepresented, despite alleged public commitment towards equality and intolerance of discriminatory practices. It has been highlighted that BMEs are generally unaware of the rights that protect them from racial and religious harassment in the workplace and resign to tolerance on the general notion that challenging the status quo may affect one's career prospects. This study therefore investigates the barriers they face causing their underrepresentation in construction and the consequences of these actions on their uptake and its industrywide effects.

Keywords:
BME, ethical, sustainable, diversity and employment.

1 Introduction

Nations have witnessed population diversities to the extent that monolithic blocks of workforce in organizations will leave them very uncompetitive on the global scene and in today's world of globalisation, this can be very detrimental. This has resulted in an unparalleled impetus for a relatively large number of studies on the effects of diversity at work and the construction industry is no exception. The need for the inclusion of minorities for the industry to be representative of the larger population is, in effect, paramount and has been covered in several studies (Caplan et al, 2009; Ahmed et al, 2008; Caplan and Gilham, 2005; Sodhi, 2004; Steele and Sodhi, 2004; Egan, 1998; Agapiou et al, 1995; Latham, 1994). However, studies into diversity at the workplace have generally yielded mixed results with some demonstrating that diversity can have negative effects by giving rise to communication difficulties thus affecting group cohesion and resulting in dysfunctional conflict (Jackson et al, 2003; Williams & O'Reilly, 1998). Yet, others (e.g., Caplan, et al 2009; Ahmed et al, 2008;

Dinsbach, 2005; De Vries & Pettigrew, 1998; De Vries, 1992) indicate otherwise and hence see no reason why such problems should occur.

The role migrant workers play in reconciling supply and demand of skilled labour in the UK construction industry needs serious scrutiny (Chan et al, 2011). However, Schaafsma, (2008) has noted that little attention has, so far, been paid to why inter-ethnic relations may be more harmonious in some work settings but rather more problematic in others as indicated by Jackson et al. (2003) and Milliken & Martins, (1996) while asserting that generally, relations between workers with different ethnic backgrounds have only been explored as potential mediators of the effects of diversity on work group outcomes. There is, as a result, little research into the experience of ethnic minority and majority employees and managers about how working in a diverse environment involving different ethnic groups can have positive or negative impact on productivity. Therefore, this article seeks to fill this gap by bringing to the fore the possible barriers that need to be understood and surmounted in order to create a positive inter-ethnic work relationship in construction. How do ethnic minority and majority members compare in dealing with inter-ethnic relations at work? And, whether either report on more positive or more problematic inter-ethnic relations. Is the former group over-blowing their experiences or is the latter covering up incidents of discrimination and how such issues are dealt with?

2 Background and Socio-economic Considerations of BMEs

The past few decades have seen Britain change from a country of net emigration to one of immigration at a trend influx of more than 100,000 immigrants annually (IPPR, 2010). Notwithstanding, improved economic performance in the UK relative to overseas has tended to increase immigration and rising UK inequality has had an even larger effect. Additionally, immigration policies at home and abroad have also helped to increase net immigration, particularly in the 1990s. According to the Labour Force Survey, some 4.5 million individuals living in Britain in the year 2000, 9% of the population, were born in another country (LFS, 2001). Many of these individuals of foreign origin work, and contribute to economic prosperity and well-being. And as supported by several studies, (e.g. Zimmermann, 2008; Dustmann et al, 2003; Shields and Wheatley Price, 2002; Dustmann and van Soest. 2001) differences in education, the demographic structure, culture, and skills of foreign-born individuals may have advantages in some labour market segments, but disadvantages in others and construction is classed in the latter category.

However, these disadvantages may diminish depending on the changes in the underlying factors and over time, immigrants may adjust in many respects to their UK-born peers, from the accumulation of skills, collection of information, and adoption of new habits. It is worthwhile to note that understanding how labour market performance of immigrants differs from UK-born, and from each other, how these differences relate to observed characteristics, and how they change over time is an important pre-requisite for migration policy. Also, it is significant to note that while adaptation and labour market performance of immigrant populations has been subject of intensive research in the US, Canada, Australia, and also in some European countries, according to Dustmann et al (2003), relatively little is known about the absolute and relative performance of the immigrant community living in Britain.

Notwithstanding, it is generally the case that when immigrants arrive in the destination country, their labour market productivity is likely to be different from that of their indigenous counterparts; a situation attributable to different levels of education, socio-economic characteristics, and different demographic composition. But even if an immigrant is compared, for example, with a UK-born of the same education and age, they may differ in labour market outcomes, like wages and participation. One important reason for this is that the skills immigrants have acquired in their home country are often not directly transferable to the host economy. Furthermore, immigrants may also lack certain general skills immediately after arrival in the host country especially fluency in communicating in the host's language as well as the observance of certain cultural practices. However, they may adjust over time to a level commensurate with the skills requirements of the labour market and in most cases acquire new skills. At this point, they may match or even do better in the level of local economic performance as well as assimilate into the hosts culture and hence the community.

Furthermore, Dustmann et al, (2003) note that differences in demographics, education or skills may but only be some of the reasons why immigrants differ in their labour market outcomes as they tend to settle in areas of more economic prosperity to take advantage of high levels of employment and wages and in most instances close to their predecessors and relations of similar origins. Consequently, this leads to selective settlement, as is the case in the South East and London regions and may cause a less even spread of immigrants and hence concentration in particular industries. This could result in more favourable labour market outcomes of immigrants and so underestimate the differences in economic outcomes between the hosts and immigrants and their descendants. Apparently, this ideal situation does not usually apply to immigrants as labour supply outstrips demand causing in its wake further unemployment thus worsening their plight.

2.1 The Impact of Economic Downturn on Future Skills Requirements

The preceding paragraph has noted that it usually happens in the case of an efficient labour market where the supply of skills is aligned with labour market demand that the supply and demand matching processes are seen to be deficient whenever there are mismatches between demand and supply for skills. As a result, considering the idiosyncratic, project-based nature of construction characterized by its reliance on a mobile, itinerant and largely self-employed workforce as noted by Chan et al, 2011 mismatches in the supply and demand of skilled manpower remains inevitable as the industry continue to remain adamant in opening to diversity.

Therefore, it is easier to assume that skill shortages, skills gaps and general unemployment have been controlled in the current situation. This fact is consistent with the Construction Trade Survey (2012), where organizations across the construction industry all reported a considerable decrease in skill shortages to a record low. For instance, for the first time since the survey began, relatively few employers experienced any difficulty recruiting site trades in 2012 Q1 as labour was plentifully available, without a single respondent suggesting any difficulty but for a modest increase in the number of firms reporting difficulty attracting appropriately skilled bricklayers and plasterers at 14% and 11% of respondents respectively.

Yet, looking at the recruitment activity, one in ten employers (10%) felt that there had been times when they lacked the number of skilled workers they required (ibid). Again, around half (52%) felt that they had been operating at around full capacity given the number of skilled staff they employed and still a third had not had enough work for their workforce (ibid). Also, it is worth noting that a more recent review of the Migration Advisory Committee (2009) recommended shortage occupations and listed civil engineers, mechanical engineers and welding trades while noting that although falling employment, vacancies and a high redundancy rate indicate that the labour market is in turmoil, it should not be assumed that all labour shortages disappear upon the acknowledgement that the removal of some construction-based occupations from the original list is in response to changing economic circumstances. Thus implying that the shortages experienced prior to the recession has only been marred by the downturn and could resurface sooner or later. Table 1 below shows the recent employment rate for construction as it compares with all other industries in the UK.

Table 1: Employment rate in Construction Compared with All Employment by Industry Sector (000). Source: Office for National Statistics, Labour Force Survey (2012)

	All in employment			***Construction***			***Real estate activities***		
	All	Men	Women	All	Men	Women	All	Men	Women
Jan-Mar 2010	28,72	15,28	13,442	2,201	1,966	235	261	118	143
Jan-Mar 2011	**29,1**	**15,5**	**13,57**	**2,20**	**1,94**	**254**	**296**	**131**	**165**
Apr-Jun 2011	29,15	15,63	13,520	2,187	1,931	256	305	143	162
Jul-Sep 2011	29,17	15,62	13,546	2,228	1,998	230	298	154	145
Oct-Dec 2011	29,20	15,63	13,568	2,165	1,934	231	290	150	141
Jan-Mar 2012	**29,1**	**15,6**	**13,54**	**2,14**	**1,90**	**236**	**331**	**177**	**155**
Change on year	*5*	*32*	*-27*	*-59*	*-40*	*-19*	*35*	*45*	*-10*
Change %	*0.0*	*0.2*	*-0.2*	*-2.7*	*-2.1*	*-7.4*	*11.8*	*34.4*	*-6.3*

As the data highlights in table 1 above, the construction industry has been significantly affected by the economic downturn, with the unemployment rate far exceeding the national average as indicated by the negative figures shown. Even the related real estate sector activities have been affected with -6.3% in female employment compared with a meagre -0.2% overall. Here it is worthwhile to note that the unemployment rate affects women employees more as noted by Wilkinson (2006) signifying that like these women, the industry has no room for BME professionals and people with disability who do not conform to the 'white, male , able bodied norm.

Therefore, it must be stressed that the impact of the recession across the construction industry has radically affected the mismatches between demand and supply. While on the one hand skills shortages and skills gaps have decreased dramatically, this has contributed to worsening unemployment. Although skills shortages are currently at an all time low, lessons need to be learnt from the previous recessions. One of the biggest risks to the recovery of the construction industry, according to the ConstructionSkills (2009) is a shortage of skills as people made redundant seek new careers outside the industry and new entrants unable to get jobs, look elsewhere. With a proportionally larger proportion of the population with a younger profile compared with an insignificant fraction engaged in construction as indicated in table 2, there is

the need for lessons to be learnt if the industry is to avoid a catastrophic future in meeting it recruitment requirements

Table 2: Employees and self-employed in the construction industry by ethnic origin in UK
Source: Labour Force Survey, Office for National Statistics (2012)

	Breakdown of Ethnic Minority[1]							
Four quarter average: Quarter 2 2010 to Quarter 1 2011	**All**	**White**	**Ethnic minority**	**Asian/ Asian British**	**Black/ Black British**	**Chinese**	**Mixed**	**Other**
(Thousands)	2,155	2,056	99	51	22	1	5	13
Percent	100%	95.4%	4.6%	2.4%	1.0%	0.0%	0.2%	0.6%

Notes: 1. The sum of ethnic minority breakdown does not equal the total due to insufficient data.

.

As can be seen in table 2, only 4.6% of BMEs compare with 95.4% of Whites are employed in construction. It is therefore evident that little improvement, with respect to drives to improve the representation of ethnic minorities, has been achieved.

2.2 Employment and Engagement

The first two definitions of employment by the Oxford dictionary online given as '*the state of having paid work*' as in '*a fall in the numbers in full-time employment*' and the action of giving work to someone as '*in the employment of an engineer'* directly fit the description of this study. Again, the Cambridge business dictionary online defines employment as '*work that you are paid to do for a particular company or organization'*. The free dictionary online also gives *engagement* as a direct synonym of '*employment'*. Although employment is much broader, and engagement entails a level of commitment, it denotes the full commitment of an employee when the two terms are used together. In fact for the employee to be motivated to contribute their best to an organization they must be well engaged in consideration to the full ramifications of the term. In human resource management this is a very important phenomenon as it defines the success or failure of a business. Research by the Institute of Employment Studies (IES) has shown that when employees feel engaged, they feel more positive about their organisation which feeling leads to enhanced motivation, performance, job satisfaction and quality of working life. There is an increasing body of evidence that employee wellbeing and engagement has a direct relationship with positive business outcomes (Shutler-Jones, 2011).

Robinson et al, (2004) again delineate issues that help a clear view of the behaviours demonstrated by the engaged employee and are seen to have clear overlaps with the concepts of commitment and organisational citizenship behaviour. According to them, engagement is big in the HR consultancy market, yet there is a dearth of academic research in this area. In their study, engagement is more than a passing fad as it brings clear business benefits. Demonstrably, there is an equally strong relationship between engagement and the drive in most organisations (Macleod and Clarke, 2009) to ensure their workforce reflects the diversity of the UK's population as ensuring fairness and equal opportunities at work for all employees lies at the heart of engagement. The focus should, as a result be on trying to keep the widest possible pool of talent available which requires that all types of employees are considered (Stern, 2008).

In a bid to measuring engagement, attitude surveys of employees based on data from the Institute of Employment Studies yielded positive responses which identified issues that drive the willingness to go beyond the requirements of the job. These underpin the determination of the level of engagement sustainable in particular instances. It had been further revealed that engagement levels can vary, in association with a variety of personal and job characteristics and with experiences at work. Some key indicators of this fact included the finding that minority ethnic respondents have higher engagement levels than their white colleagues (Robinson et al, 2004). This fact is affirmed by the argument of the industry's unwillingness to adapt its current norms to diversity which is at the root of its persistent failure to reflect diversity in the society it serves. It is further noted that the industry is "vertically divided into distinct socio-economic groups raising a difficulty in knowing how to get more women and other minorities into the industry. Consequently, construction is compared to the army; with strong officer, supervisor, and cannon fodder classes where every man knows his place and *who* is above and below him (Johnson, 2003). With these characteristics, 'fitting in' is central if one is to be retained (CCI, 2010, Ahmed et al, 2008). Another important barrier besides having to fit a mould (Ahmed et al, 2008) is the observation that getting ahead in construction is often characterised by the importance of personal relationships where '*men tended to have chosen a construction career in response to a family member'* (Dainty and Bagilhole 2006) while *younger women tended to have embarked on a construction career as a result of targeted recruitment campaigns*" (ibid).

As a result, organisations need to work harder to minimize, or better, prevent, the impact of bad experiences. They also need to ensure that employees' development needs (including the special needs of professionals) are taken seriously; pay attention to, and value the roles of, support staff; and to maintain the interest of longer-serving employees. The relatively high levels of engagement of the oldest employees, and of minority ethnic staff, suggest sources of untapped potential within some organizations (Macleod and Clarke, 2009).

3 The Study

Therefore, in order to further investigate the underrepresentation of this *sustainable* source of labour to construction beyond literature, empirical data was collected from stakeholders in the industry. This entailed the collection of qualitative data using semi-structured interviews from construction employers (managers, supervisors etc.) in both large companies and Micro to SMEs through the use of snowball sampling. This was necessary due to the difficulty in recruiting respondents. Of the 22 interviews (referred to as RP1 –RP22), 8 were conducted in the North West of England while the remaining 14 were conducted in London and the South East. Additionally, 75 questionnaires were received back from respondents for a quantitative study alongside, which entailed a further 28 and 47 questionnaires from the North West Region and London and the South East Region respectively. In all 200 questionnaires had been distributed equally in both locations in this *pragmatism* oriented study. These were analyzed using Nvivo8 in the first case and SPSS in the second instance. Hence the mixed methods approach characteristic of the pragmatic paradigm (Creswell 2003) using strategies for data collection in a parallel/ simultaneous manner (WBI, 2007) was adopted through the use of techniques drawn

from both the quantitative and qualitative traditions. In the study, themes were identified and the discussion in this paper will be based on the single main theme outlined in section 4 below.

4 BME Employment and engagement barriers

For the purpose of this article the salient references as captured in Nvivo 8 relating to the theme 'BME employment barriers in construction' are capture and emphasised in order to drive home the issue at stake. It has been noted that England has become so diverse ethnically but the question still remains whether this diversity is reflected in the various institutions or there exist clusters of ethnicities visibly identifiable in sectors peculiarly identified as such. This theme was exhaustively reviewed by the respondents with all 22 of them contributing 46 references to the issue implying an average of two references each and in some cases three. The content and the context of such references will form the subject of discussion in this section.

Here, the educational level, the knowledge and expertise as well as the experience base of BMEs was called to question and is put in doubt. RP1 contends that some of 'them'- (BMEs), may suffer from lack of knowledge, education and familiarity with local issues implying the lack of knowledge of the local culture and goes on to say that if one has work experience in the appropriate field, it does not matter what race, being Asian, Black or White, a job could be obtained in construction; a point also confirmed by RP4, RP8, RP10, RP14 as signified by this quote: *"Lazy people always point accusing fingers. As they say, the bad workman … They don't want to train and so … blame their tools. Indians are everywhere. What about that. They are BMEs as well, aren't they?"(RP22)* But then the issue of the '*Indians are everywhere*' is rebutted by the argument that the industry is dominated by the white majority and if Indians happen to be the majority among the minority as indicated in table 2 where they constitute more that halve (2.4% out of the 4.6%) of the total BME employees in the industry and as noted by literature then their success reflects the character of the industry reminiscent of the White male dominance. Also where clusters are formed with dominance in some parts for particular minorities such practices could prevail. The remedy, as a result lies in something else and citing the incidence of over-education as noted in literature and elsewhere in this study point in a different direction.

Also, related to the issue of the lack of adequate training is that of language which was seen to be a problem but then again a rebuttal by RP18 had this effect: *"I not think so … people difficult to speak English but work is not speak ... know language too much plenty talk. A little English ... that's enough."(RP18*). It is evident that the language of the respondent has a lot of room for improvement and as an employer leaves much to be desired. Therefore the issue of language is given varying dimensions based on what is being considered. Alluding to scanty English as a means of getting employee to stay focused on their duties is how RP18 believes limited language skills can be an advantage believing that '*work is not speaking*" however noting the significance of explicit instructions.

The issue of racial and other forms of discrimination on ethnic lines have also been outlined in literature as a subject of much scrutiny. Being quite controversial an issue which a lot of people would avoid, it is quite sensitive to be discussed. However, it

featured a lot in the responses and it is believed that a little elaboration will do. Confirming the literature, the respondents made references to discrimination as not only meted out to minorities by the majority but the reverse is also the case and also, even amongst the minorities, there is a lot of discrimination. Therefore, it is common for companies, especially micro and SMEs to be characteristically dominated by clusters of particular ethnic groups.

Final to be discussed here is the major and dominant barrier raised which is the lack of network for the BME community in the construction industry as noted by Dainty and Bagilhole (2006) and Ahmed et al, (2008). Several respondents referred to the fact that recruitment is through informal referrals by staff and other known people who bring in relations and friends as confirmed by: *"I think in construction, it is best if you know somebody ... I remember ... a friend brought me to my first job" (RP 10).* This factor happened to be the most prevalent among the respondents and has been captured along with others into the model adapted from the Commission for Architecture and the Built Environment (CABE, 2005) on what it describes as *helping* and *hindering factors* on either side. The effects of these factors during the employment process are graphically demonstrated depicting a reduction in numbers from education and training through job seeking to senior management respectively (Figure 1). The model shows this effect as the involvement of BMEs narrows down along this process.

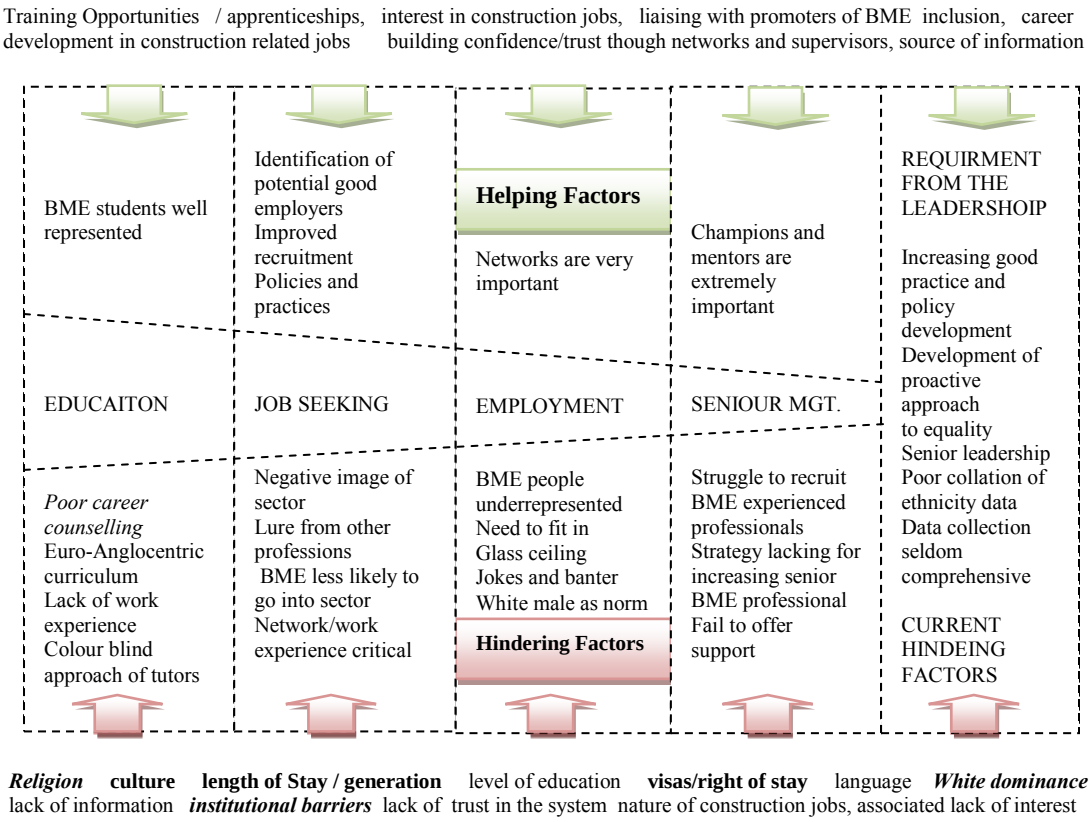

Figure 1: Model of helping and hindering factors excerpted and adapted from CABE (2005)

The factors as noted in the two instances of helping and hindering factors in figure 1 stress the importance of networks as noted earlier thus confirming the tendency of *like*

attracting *like* and rather contradicting the law of magnetism. The adage '*birds of a feather flock together'* therefore becomes the norm and hence the formation of clusters of ethnicities in particular job locations. The issue of trust and commitment which hints levels of engagement as discussed in section 3 is seen to be pivotal here.

Additionally, as a corroborative study, the quantitative analyses concentrated on the importance of networks in gaining access to the industry as confirmed in literature and in the qualitative part of the study. This point was arrived at by the correlation between two variables '*Relation in industry'* and '*mode of entry'* in both regions, as indicated in figures 2a and 2b. In the figures, it is evident that strong networks in the industry are a determinant of the opportunities open to potential employees.

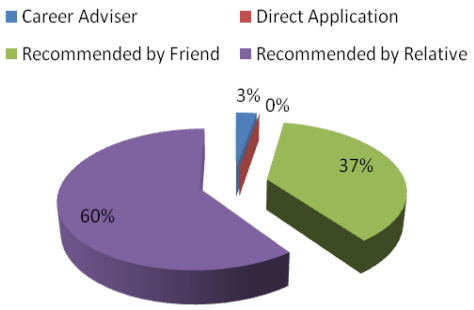

Figure 2a: Relation and mode of entry (SE)

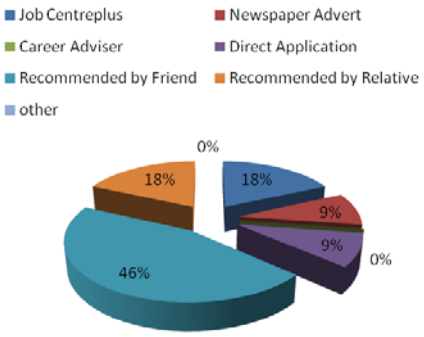

Figure 2b: Relation and mode of entry (NW)

The percentage of the respondents in both regions who gained accessed is evident and indicative of the evidence tended by Dainty and Bagilhole (2006) that '*Men tended to have chosen a construction career in response to a family member ...* implying that they were attracted by relations in the industry. In the case of the South East (SE) in figure 2a a whopping 60% of the respondents were attracted by relative with a corresponding 18 in the North West, while 37% and 46% respectively gained access through friends. Going by these figures, it is confirmed that networks are a crucial means of entry into construction.

4 CONCLUSION

In effect, it has been noted that the foregoing points to the variety of sources of the barriers facing prospective entrants into construction in the United Kingdom. Ethnic minority workers may be disadvantaged by their own characteristics in what might be regarded as internal barriers, yet other distinct factors and external barriers are at play. The Labour Force Surveys (LFS) data indicate that 16% of those whose first language is not English claimed that language difficulties caused them to have problems in finding or keeping a job. Also, data from the Fourth National Survey of Ethnic Minorities report that lack of English language fluency reduces average predicted employment probabilities by 20-25 percentage points. In most dimensions of economic and social well being (such as income, employment, education, social class, health, housing etc.) there is a clear ethnic hierarchy with Indians and Chinese at the top, Black Africans and Caribbeans somewhat lower down and Pakistanis and Bangladeshis at the bottom. This stratification is not by accident and points to some of the evidence discussed in preceding sections.

This study, therefore, has stressed the importance of networks in the process of employment through retention and progression which has received confirmation in literature and in the empirical study. This mode of entry has tended to favour the White majority and as has emerged above the clustered majority amongst the minorities who have already been able to make their mark like the Asian or Asian British, particularly the Indians as indicated by some respondents. Such processes may derive from sources including public perception which has been thought to be prejudiced against people of other races other than the white majority yet it had also been noted that reverse discrimination is also possible. Cognisant of this fact, therefore, the formation of clusters and discrimination along such lines have not been ruled out hence the minority being disadvantaged in all respects.

In all this however, the United Kingdom policy interventions and existing national legislation need to be focused on stemming the tide by removing racial barriers to labour market integration. While it is clear that the weak labour market outcomes for ethnic minorities are due to a number of other causes as well that are beyond legislative control, it is also evident that a lot remains desirable in that respect. In particular, in the United Kingdom, policy is driven by the Race Relations Act (2000) that focuses on extending the duties required in the public sector to the private sector and as construction is mainly in the latter but heavily controlled and financed by the former, a lot of improvement of policy initiatives in place when properly implemented and monitored, (and the stress is on monitoring) may help stem the tide as recent positive stance on ethnic minority issues is encouraging.

These developments make further study on interethnic relations at work all the more warranted and targeting construction as the driver of most economies will go a long way to achieve the desired effect. In the workplace, people may have to interact with members of ethnic out-groups who they would perhaps avoid in their private lives. This may result in tensions, however if the workplace is oriented to a context in which people inculcate tolerance it may help to develop more positive attitudes toward each other as well as the common objective of fulfilling assigned tasks. There is also the need to consider whether the conditions of minorities are hyped and if some members of the native majority do not suffer similar fate yet shy at reporting it.

CONSTRUCTION DELAY EFFECTS AND MINIMIZATION IN INDIGENOUS AND MULTINATIONAL FIRMS

Abisuga Olatunji[1], Oyekanmi Olugbenga[2] and Egbera Tricia[3]

[1, 2, 3] *Department of Building Technology, Lagos State Polytechnic, Nigeria*

ABSTRACT

The issue of delay in construction industry is a global phenomenon and the construction industry in Nigeria is no exception. The study is to assess the effects of construction project delay and suggests methods to minimize them. A questionnaire survey was conducted to solicit the effects of construction delay and methods to minimize them from the indigenous and multinational construction firms. A total of fifty-eight (58) questionnaires were used for the analysis. The study revealed that time overrun; diputes, cost overrun, litigation/arbitration and project abandonment were the major effects of delay of construction projects. The five most effective methods of minimizing delay were frequent progress meeting, proper site management and supervision, proper coordination between the parties involved, proper material procurement and commitment to projects by all parties concerned.The study also established an empirical relationship between the methods employed in minimizing construction delay by both indigenous and multinational construction firms.

Keywords: construction project, delay, indigenous, minimizing, multinational.

INTRODUCTION

The Construction industry produces various resources, infrastructure, and facilities that aid the day to day human activities. Then the construction industry is vital to growth and development; its activities also forecast the general direction of an economy and for this reason, the industry is often described as a leading economic sector. Though, government spending is a major contributor to the industry, especially the infrastructure sub-segment, other sectors also contributed positively on the industry's growth.According to Aibinu and Jagboro (2002) a major criticism facing the Nigerian construction industry is the growing rate of delays in project delivery. Assaf and Al- Hejji (2006), define delay as the time overrun either beyond completion date specified in a contract, or beyond the date that the parties agreed upon for delivery of a project.A successful project is that, which accomplished its technical performance (in terms of quality and safety), maintained its schedule, and remained within budgetary cost (Frimpong Y.,et al 2003).The studies carried out in Nigeria by

[1] abisuga_olatunji@yahoo.com

[2] boyeksassociates@yahoo.com

[3] kemitricia@yahoo.com

Odeyinka and Yusuf (1997) showed that seven out of ten project suffered delays in their execution. It was also observed that construction projects overrun their duration by 40 – 50% (Aibinu and Jagboro 2002).Ajanlekoko (1987) observed that the performance of the construction industry is poor in terms of time. Actually the problem of delays in the construction industry is a universal issue. In Saudi Arabia, Assaf and Al-Hejji (2006) found that only 30% of construction projects were completed within the scheduled completion dates and that the average time overrun was between 10% and 30%.

Construction contractors (firms) are usually categorised by several criteria.In Nigeria, the scope of operation is a common criterion.Researchers use this criterion to categorise contractors into either national (indigenous) or multinational (Samuel 1999, and Olateju 1991).National (indigenous) firms are those firms whose scope of operation is limited to Nigeria while multinational firms are those who operate in foreign countries as well as Nigeria.By virtue of their scope of operation, the former operates within existing regulations and standards in Nigeria which can be described as local regulations while the latter operates within local and foreign regulations and standards. Some multinational even pefer to adopt international regulations and standards such as Bristish Standard (BS), US Standards and International Standard Organisation (ISO) and so on.The indigenous construction firms are majorly one man business, but some are into partnership.Their organisation size vary between 1-3 staffs count,with an organisational structure comprising of the managing directors, a site personnel and a secretary.The size of their firm is determined by the ongoing projects so that cost of overhead for staffing is reduced, they rely more on casual staffs. In terms of equipments, finance, human resources, and so on the indigeneous firms were lacking behind compared to the multinational firms. The multinational firm comprise of mixed management of foreign expertriate and indigenous staffs. Their organisation capacity covers human resources, technical and managerial know-how, equipments, finance, technology, and information.Their organisation size vary between 4≥30 staffs count, with an organisational structure comprising the directors, management teams, operational teams, technical teams, support staffs and so on. Basically; those factors give the multinational firms a better performance than the indigenous firms.Ogbebor 2002, noted that 96% of the Nigeria construction industry is dominated by foreign contractors. On the grounds that indigenous contractors cannot be entrusted with complex project because they are incompetent.The issues of construction delays is particular to both the two firms' types, but the indigenous firms are most criticize for it than the multinational firms.

Different academic researchers have studied the causes of construction delays, its effects on project delivery in terms of time, cost and quality and methods of minimizing construction delays.Majorly, their comparism lies between professional respondents, contractors and the clients. The differential pattern between the activities and performance of the two types of construction firms in Nigeria in relation to construction delays has to be examined. The objectives of the study are to examine the effects of construction delays and the methods to minimizies it from the preception of both the indigenous and multinational construction firms. The paper also seeks to establish whether there is a statistical relationship between the preception of the firms' types.

Studies on effects of delays on construction projects

Delays in construction have so many effects which have been studied by few academic researchers. Li et al (2000) showed the effects as additional costs, decline in quality and rework, loss of productivity, late completion of project, increased time related costs, third party claims, and termination of contract. Aibinu and Jagboro (2002) studied and evaluated the effects of construction delays on project delivery in Nigerian construction industry. They discovered that the six effects of construction delay were: time overrun, cost overrun, dispute, arbitration, litigation, and total abandonment. Abdul-Rahman H. et al (2006) in their study found that delays effects were the disruption of work, loss of productivity, late completion of project, increased time related costs, third party claims and termination of contract.

Claims reinburstment issues between owner and contractor are always tense due to extra cost and time enlongation associated with delays.Thus, delay could generate distrust and create tension between the contractor, owner, and the owner's project management team according to Aibinu (2009). Ahmed et al (2002), stated that delay have a debiltating effect on clients, contractors, and consultants in terms of growth in adversarial relationships, mistrust, arbitration, cash flow problems, and a general feeling of trepidation towards each other.Aibinu and Odeyinka (2006) revealed that processing time and cost related claims associated with delays always generate dispute and further delays.

Studies on methods of minimizing construction delays

For a project to be successful; delays must be minimized or reduced.Aibinu and Jagboro (2002) identified two methods of minimizing delays which are: acceleration of site activities and contingency allowances. Odeh and Battaineh (2002) recommmend that reinforcement of liquidated damages clauses and offering incentives for early completion, developing human resources, adopting new contract award approach such as design-build and construction management contract type can minimize construction delays. A study carried out in Kuwait by Koushki et al (2005) identified methods of minimizing delays which include: ensuring an adequate source of finance, performance of pre-construction planning, allocation of sufficient time and money during the design phase, hiring of independent supervising engineer to monitor progress of work and ensuring timely delivery of materials and selection of competent and reliable consultants to carry out the work.Dayang (2009), identified proper project planning and scheduling, developing appropriate communication system linked to all functional groups, ensure the availability of resources, hiring a competent project manager and utilization of appropriate construction methods, incentive offer for early project completion and emphasizing on the availability of resources.Abudul-Rahman et al (2006) identified the procedures taken by contractor as to recovery of delays. From their survey, recommended procedures were increasing the productivity by working overtime hours or working by shifts, followed by asking for extension of time.

METHODOLOGY

A questionnaire was developed to assess the perception of the indigenous and multinational construction firms on the effects of construction delays and various methods that can be employed to minimize delays in construction projects in Lagos, Nigeria. The questionnaire was divided into three parts. The first part requested background information about the respondents.

The second part of the questionnaire focused on effects of construction delay among stakeholders. The eight effects of construction delay identified were: time overruns; cost overrun, dispute, arbitration, litigation, inability of client to get quick returns on investment, shortage of housing and project abandonment. Similar to the second part, in the third part of the questionnaire, the respondents were asked to highlight their preception on how to minimize the effectsof construction delay based on fifteen (15) factors identified. A five point likert-scale ranging from 1 (Not affect) to 5 (very great affect) was adopted to capture the effects of construction delay. Similarly, a likert-scale ranging from1 (Not effective) to 5(Very high effective) was used to measure the effectiveness of the methods employed to minimize construction delay.The sampling method used for the study was random sample techniques.The total of seventy (70) sets of survey questionnaire was distributed covering both indigenous firms (40nos) and multinational construction firms (30nos).Of the 70 questionnaires, Fifty-eight (58) sets (82.9%) were returned and there were 32 sets (55.2%) from indigenous firms and 26 sets (44.8%) from the multinational firms. The likert- scale adopted was transformed into mean score for each factors and ranked. Spearman Rank Correlation (Rs) was used to establish whether there is any form of significant relationship between the indigenous and multinational construction firms in relation to the effects of construction delays and the methods employed to minimize delay during construction project execution in the organisations.The hypotheses stated, were (a) H1: There is no statistical significant relationship between the effects of construction delays as perceived by the indigenous and the multinational firms. (b) H2: There is no statistical significant relationship between the methods of minimizing construction delays as precieved by the firm's types.

Spearman Rank Correlation (Rs)

$$Rs = 1 - \frac{6\sum d}{n(n^2-1)}$$

Test for significant (t)

$$t = rs\sqrt{\frac{n-2}{1-rs^2}}$$

ANALYSIS OF DATA

Demographic characteristic of respondents are given in Table1, according to the table, 32 questionnaires were received from the indigenous construction firms and 26 from the multinational firms. The designation of the respondents from the two types of firms differs; where majority were builder (36.2%). The work experience of the respondents lies more within 0-5 years for the indigenous firm's and 6-10 years for the multinational.The staff strenght of the multinational firms are more than the indigenous firms. Most of the firms specialize in building and civil engineering works.

Effects of construction delay

The primary data collected from the second part of the questionnaire was analyzed from the perspective of the indigenous and multinational construction firms. The mean score was computed for each effect of construction delays to identify the most critical effects. The effects were ranked based on mean score values. From the ranking assigned to each effect of delays, the most critical effect as it concerns the two firms was identified. Based on the ranking in table 2, the five most critical effects of construction delays as preceived by the indigenous construction firms were: time overrun (4.06), dispute (4.00), cost overrun (3.91), project abandonment (3.72), and arbitration (3.51). The five most critical effects of construction delay as perceived by the multinational firms were: dispute (3.81), litigation (3.81), arbitration (3.80), time overrun (3.77), and project abandonment (3.58).From the above list, it is shown that the effects of construction delays on the two firms' types have a differential pattern. Thus, the effects were same but their critical level from the preception of the two firms differs. Based on the overall weight ranking for both the indigenous and multinational firms the five most critical effects were: time overrun (3.92), dispute (3.91), cost overrun (3.73), litigation/arbitration (3.66), and project abandonment (3.65).

Table 2: Effects of delay

Effects of delay	**indigenous Mean (x)**	**Rank**	**Multinatioal Mean (y)**	**Rank**	**overall weight(z)**	**Rank**
Time overrun	4.06	1	3.77	4	3.92	1
Dispute among construction parties	4.00	2	3.81	1	3.91	2
Cost overrun	3.91	3	3.54	6	3.73	3
Litigation	3.50	6	3.81	1	3.66	4
Arbitration	3.51	5	3.80	3	3.66	4
Project abandonment	3.72	4	3.58	5	3.65	6

Shortage of housing for people	3.19	8	2.92	8	3.10	8

Source: field survey 2011

From table 3, the spearman rank correlation coefficient calculated was 0.464 shows a weak positive correlation between the preception of the firms types on construction delay effects.The calculated value (t_{cal}) is 1.45 and the critical value (t_{tab}) is 1.895. Ho was accepted. This shows that the observation is not statistically significant.The differential pattern of the effects of construction delay on the indigenous firms and the multinational firms is below average.Hence, there is no statistical significant relationship between the effects of construction delay percieved by the indigenous firms and the multination firms.

Table 3: Spearman rank correlation of effects of construction delays

Variables	**Rs**	**df**	**t_{cal}**	**t_{tab}**	**decision**
effectsof delay	0.464	7	1.45	1.895	Accept H1

Methods of minimization of construction delay

The primary data collected from the third part of the questionnaire was analysed from the perspective of the indigenous and multinational construction firms. The mean score was computed for each method employed by the firms to minimize construction delays. The most effective methods of construction delay minimization were identified.Based on the ranking in (table 4), the five most effective methods of minimizing construction delays as perceived by the multinational construction firms were: proper site management and supervision (4.34), appointment of a competent project manager (4.34), commitment to projects by all parties concerned (4.34), frequent progress meetings (4.25), and proper material procurement (4.03). The five most effective methods of minimization of construction delay as percieved by the indigenous construction firms were: frequent progress meetings (4.27), proper coordination between parties involved (4.27), proper material procurement (4.23), proper information and communication flow (4.23), and proper site management and supervision (4.04).

Table: 4 Methods of minimization of construction delays

Methods of minimizing delay	**indigenous Mean (x)**	**Rank**	**Multinational Mean (y)**	**Rank**	**overall weight(z)**	**Rank**
frequent progress meetings	4.27	1	4.25	4	4.26	1

Source: field survey 2011

The spearman rank analysis was used to study the relationship between the perception of the indigenous and the multinational firms on the methods employed to minimize delay in construction projects. The calculated value (tcal) is 4.07 and the critical value (ttab) is 1.76. $H_1$was accepted. There exists a statistical significant relationship in the preception of the indigenous and multinational construction firms on methods of minization of delay. The value of Rs is 0.652 which shows a strong positive relationship within the differential pattern of the preception of the two firm types (see table 5).

Table 5: Spearman rank correlation of methods of delay minimization

Variables	**Rs**	**df**	**tcal**	**ttab**	**Decision**
methods of minimizing delay	0.652	14	4.07	1.761	Reject H2

Discussion of results

The results obtained in the earlier section shows that the five most critical effects of construction delay (based on both firms types) as shown in table 2 were: time overrun (3.92) dispute among construction parties (3.91), cost overrun (3.73), litigation/arbitration (3.66), and project abandonment (3.65). The results confirm the study of Aibinu and Jagboro (2002).

According to Murali and Yau (2007) the causes of time overrun can be due to inadequate planning by the contractors, improper site management by the contractors, inadequate project handling experience of contractors, and delay in the payments for the work completed.

Cost overrun in construction project execution can be caused by change orders, mistakes, and discrepancies in the contract document. Disputes among construction parties can arise due to such factors as delay in the payments for completed work, frequent owner interference, changing requirements, lack of communication between the various parties, unforeseen site conditions, and problems with neighbors.Project abandonment can be caused by either, client-related, consultant-related, labor-related, contract-related and external factors (Murali and Yau 2007).In terms of disputes, dispute resolution is vital, and if not managed properly, can lead to abritration and litigation.

In Lagos, Nigeria, most project abandonment experienced were basically due to financial issues from client (individual, corporate and Government), death of the owner, change of government or policy and administrative-related issuses (corporate and government).

The five most effective methods of minimization of construction delays for the two firm's types were: frequent progress meeting, proper site management, and supervision, proper coordination between the parties involved, proper material procurement, and commitment to projects by all parties concerned. These factors, if well implemented by both the indigenous and multinational construction firms will reduce issues of delays in construction project execution.

CONCLUSIONS

The study focused on the effects of construction delays and methods employed to minimize the occurence of delays during construction project execution as percieved by both indigenous and multinational construction firms in Nigerian construction industry. The study revealed that the five critical effects of construction delays were time overrun, dispute, cost overrun, and litigation/arbitration and project abandonment. The effects of construction delays affect the performance of the industry and customer's satisfaction have not been met. Basic causes of delays in the construction industry should be addressed and the strategies highlighted by the stakeholders for this were frequent progress meetings, proper site management, and supervision, proper coordination between the parties involved, proper material procurement, and commitment to project by all parties concerned. The study revealed that there is a significant relationship between the strategies employed by the indigenous and the multinational construction firms in reducing or eliminating construction delays and delay effects on the two firms types differ slightly due to the nature of the organisation setup.

CONSTRUCTION TIME: A PREDICTION MODEL WITH REFERENCE TO INDIAN CONSTRUCTION INDUSTRY

Ifte Choudhury[1]

[1]*Department of Construction Science, Texas A&M University, College Station, TX 77843, USA*

ABSTRACT

Studies indicate that there is a relationship between project cost and construction time for different construction markets. The purpose of this study was to validate the time-cost relationship model developed by Bromilow et al. (1980) in context with commercial, residential, and industrial construction projects in India. The model was extended to include the magnitude of the projects in terms of gross floor area and project delivery methods to determine whether these variables also have an effect on project duration. Data related to 99 construction projects from all over India was obtained for the study. SPSS® program was used for analysis of the data. The statistical technique used for the analysis was stepwise linear regression. The results show a statistically significant relationship between construction time and magnitude of the project, measured by gross floor area, at the level of significance (*p*-value) of < 0.0001. This variable, when introduced in the model, presumably acts as a proxy for actual construction cost. A prediction model of construction time has been developed based on the results of the study. This model will be useful to students, both at graduate and undergraduate levels, who taking courses related to construction project scheduling and international construction.

Key words: Construction Time, Construction Cost, Gross Floor Area, Indian Construction Industry

INTRODUCTION

Construction Time and Construction Cost

Time and cost have been typically used as important criteria for determining project performance globally. Project cost has been identified as a correlate of construction time in many regions of the world (Bromilow et al., 1980; Choudhury & Rajan, 2008). In the construction industry, contractors usually use previous experiences to estimate the project duration and cost of a new project. In general, the more time it takes to complete an activity, the more human resources have to be engaged for the task, resulting in a higher project cost.

[1] i-choudhury@tamu...edu

A relationship between completed construction cost and the time taken to complete a construction project was first mathematically established by Bromilow et al. (1980). For the updated model, the authors analyzed the time-cost data for a total of 419 building projects in Australia. The equation describing the mean construction time as a function of project cost was found to be:

$$T = K*C^B \quad (1)$$

Where

T = duration of construction period from the date of possession of site to substantial completion, in working days
C = completed cost of project in millions of Australian dollars, adjusted to constant labor and material prices
K = a constant indicating the general level of time performance per million Australian dollar
B = a constant describing how the time performance is affected by the size of the construction project measured by its cost.

The model indicates that the duration of project time of a construction project is basically a function of its total cost. It provided a basis for all parties concerned with the construction process to establish a fairly accurate probable duration of a project in days, given the estimated cost of the project. The authors also analyzed the overruns on cost and time that provided a measure on the accuracy of the industry's time and cost prediction.

The model also indicates that relationship between duration of a construction project and time required to complete it is non-linear. In order to perform data analysis using a linear model, the variables need to be transformed into their natural logarithms.

Several other studies have been performed around the world to make similar predictions for either a specific sector of construction or construction industries, in general. Ireland (1985) replicated the study to predict construction time for high-rise buildings in Australia; Kaka & Price (1991) conducted a similar survey both for buildings and road works in the United Kingdom; Chan (1999) investigated the effect of construction cost on time with particular reference to Hong Kong; and Choudhury & Rajan (2008) conducted a study on residential construction projects in Texas. Hoffman et al. (2007) used Bromilow et al.'s (1980) time-cost model to analyze data collected for 856 facility projects. They, however, included certain other variables such as project location, building type, and delivery method in the model. All these studies found that the mathematical model developed by Bromilow et al. (1980) holds good for prediction of construction time when the cost of construction is known.

Construction Time and Gross Floor Area

Some studies suggest that building size is a better predictor of construction time performance than project cost. One of the first proponents of using building size as a predictor of construction time is Walker (1995). He suggests including gross floor area

 ISBN: 978-1-84219-840-7 .

(which is measure of building size or magnitude) as an independent variable in the model to predict construction time performance.

Love et al.'s (2005) study takes a similar view. They argue that construction cost, when decomposed, consists primarily of labor and material costs. They argue that while labor cost is a function of time, material cost of a building is a function of gross floor area. The speed of construction, they argue, increases with an increase in the overall quantity of materials used. Therefore, the authors conclude that construction cost is not a "good" predictor of construction time performance. Instead, they advocate an importance on floor area as a viable alternative.

Given these considerations, gross floor area seems to be a promising factor for forecasting construction time of building projects. It may be worthwhile to find out whether this particular variable is a more reliable predictor of project completion time than cost.

Hypothesis

From a review of literature, it is hypothesized that

1. The actual construction time of building projects in India is affected by actual construction cost.
2. The actual construction time of building projects in India is affected by gross floor area of construction.

METHODOLOGY

Data Collection Procedure and Sample Size

Data for 99 construction projects were obtained from a database of construction projects maintained by the Indian Construction Industry. It was collected in Spring 2010. The projects consisted of residential apartment complexes and commercial buildings. All the projects were completed within last five years.

Variables and their Operationalization

Actual Construction Time (TIME): It is the actual time measured for the completion of a construction project. It was measured in months. This variable was labeled as LNTIME after being transformed into its natural logarithm.

Actual Project Cost (COST): It is the total cost of construction works of a construction project. It was measured in US Dollars. This variable was labeled as LNCOST after being transformed into its natural logarithm.

Gross Floor Area (GFA): It is the gross constructed area of a construction project. It was measured in square feet. This variable was labeled as LNGFA after being transformed into its natural logarithm.

RESULTS

Analysis

The time-cost relationship model developed by Bromilow et al. (1980) defines only the relationship between construction time and cost. Since the present study hypothesizes a

 ISBN: 978-1-84219-840-7 .

relationship to exist also between (1) construction time and gross floor area and (2) construction time and construction cost, the model had to be modified. Following model encompasses both the variables that may have an effect on construction time performance:

$$TIME = K*COST^{B1}*GFA^{B2} \quad (2)$$

A stepwise linear regression analysis was used to perform the first step of analysis (see eqn. 3). It is a semi-automated process of building a model by successively adding or removing variables based on the *t*-statistics of their estimated coefficients. Therefore, the variables had to be transformed into their natural logarithms.

$$LNTIME = LNK + \beta_1\ LNCOST + \beta_2\ LNGFA + \varepsilon \quad (3)$$

Where

LNK = natural logarithm of K,
β_1, β_2 = regression coefficients, and
ε = error term.

The results of the analysis are shown in Table 1.

Table 1. Stepwise Linear Regression Analysis for LNTIME

Variable Retained	**Intercept (LNK)**	**Regression Coefficient**	***t***	***p*<|*t*|**	**Critical Value of |*t*|**
Intercept	-1.203		-4.378	<0.0001	1.96
LNGFA		0.367	15.568	<0.0001	
F-value of the Model = 242.354	*p*>Model *F*=< 0.0001	Model R^2 = 0.714 Adjusted model R^2 = 0.711			

Interpretations

The *F*-value of the model used for multiple regression analysis was found to be statistically significant at less than the 0.0001 level. This provides evidence that a relationship exists between construction time and at least one of the independent variables used in the model. The results, however, indicate only gross floor area is correlated to construction time at a very high level of significance with a *p*-value of less than 0.0001. None of the other variables, including construction cost, were found to be significant at level of significance of 0.05; hence, they were automatically excluded by the statistical package from the model.

An important aspect of a statistical procedure that derives model from empirical data is to indicate how well the model predicts results. A widely used measure the predictive efficacy of a model is its coefficient of determination, or R^2 value. If there is a perfect relation between the dependent and independent variables, R^2 is 1. In case of no relationship between the dependent and independent variables, R^2 is 0. Predictive efficacy of this particular model was found to be moderately high with an R^2 of 0.714, and an

 ISBN: 978-1-84219-840-7 .

adjusted R^2 of 0.711. It means that at least 71 percent of the variances in construction time of educational projects are explained by gross floor area alone.

In order to have a visual understanding of the relationship between construction time and gross floor area, a scatter plot diagram was produced (Figure 1). The diagram confirmed the results obtained by stepwise linear regression analysis. A residual plot indicated a good fit of the sample data (Figure 2).

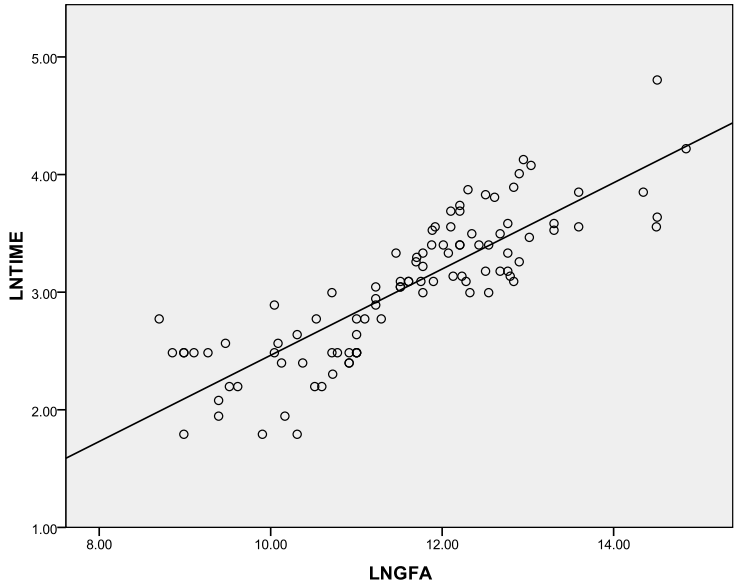

Figure 1. Relationship between LNTIME and LNGFA

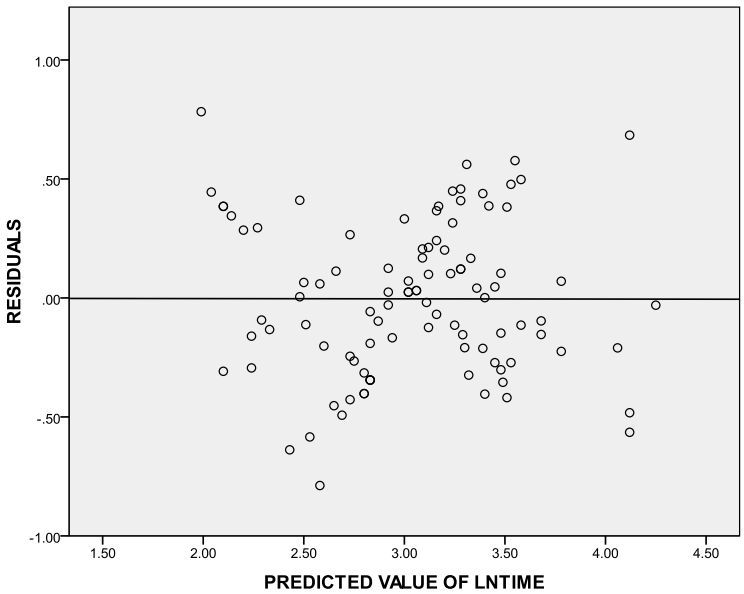

Figure 2. Residual plot

 ISBN: 978-1-84219-840-7 .

Based on the findings, research hypothesis indicating a relationship between actual construction time and construction cost of building projects in India had to be rejected. However, the other hypothesis indicating a relationship between actual construction time and gross floor area of building projects in India could not to be rejected.

The prediction model for construction time of buildings in India was developed using results of the analysis. Bromilow et al.'s (1980) model was modified by replacing construction cost by gross floor area. The value of LNK was required to be transformed to K, using an exponential function [exp(LNK)], for expressing the model in its original form (Equation 4). The value was found to be 0.3. The model may be expressed as follows:

$$TIME = 0.3*GFA^{0.367} \quad (4)$$

This model can be used to predict the construction time for a building project in India when the gross floor area in known. For example, if the gross area of a construction project is, say 50,000 sft., the predicted construction time for the project would be about 16 months.

CONCLUSIONS

The results of the statistical analysis indicate that for a construction project in India, an increase in gross floor area results in an increase in total construction time. They also indicate that construction cost does not have to be included in the prediction model when gross floor area is available. In other words, this variable also acts as a proxy for construction cost. It can, thus, be assumed that gross floor area is a better predictor of construction time for construction projects in India.

The model will be useful for students of construction science, taking courses in construction project scheduling. It will also be useful for all parties associated with the construction industry to predict the mean time required for the delivery of an educational project. It provides an alternative and logical method for estimating construction time, both by bidders and clients, to supplement the prevailing practice of estimation predominantly on individual experience. The predict construction time for projects in other sectors.

This study has been conducted using data for construction of building projects in India. The construction industry can benefit from the results of the study by applying the model in predicting construction time for similar projects. Such models may be developed by collecting historical data either from the owners or the constructors. However, the model documented in this study applies only for construction projects in India and cannot be generalized beyond the sample size.

ENABLING IMPLEMENTATION OF EARNED VALUE MANAGEMENT IN THE SPANISH CONSTRUCTION INDUSTRY

Monty Sutrisna[1,2], Eugenio Pellicer[1], Cristina Torres[1] and Miguel Picornell[1]

[1]*School of Civil Engineering, Universitat Politécnica de Valencia, 46022, Valencia, Spain*

[2]*School of the Built Environment, University of Salford, Salford, M5 4WT, United Kingdom*

ABSTRACT

The management of construction projects in Spain has been considered traditional and therefore need to integrate more contemporary project management techniques into its practices. The Earned Value Management (EVM) can be viewed as one of the project management techniques that represents the most fundamental principles of project management. Thus, promoting EVM as a common practice in the Spanish construction industry can be regarded an important step for the construction project management practices in Spain to increase its global competitiveness. Aiming to do so, this research project has been set to study the most appropriate way to promote the use of EVM in the Spanish construction industry. Initial findings from a questionnaire survey distributed to a sample population consisting construction practitioners in Spain are presented here. The preliminary outcomes of data analysis are discussed revealing the perception and practice of project management as well as the readiness of construction firms in potentially adopting EVM as the 'new' way of working in the Spanish construction industry. Subsequently, the most effective ways for implementing EVM in Spain can be formulated and this will support further research to recommend a set of guidelines to improve project management practices in the Spanish construction industry.

Keywords: Construction, Earned Value Management, Project Management, Spanish Construction Industry.

INTRODUCTION

Project management has continued to grow and develop into a multi-disciplined profession with its distinctive tools and techniques and has been gaining momentum in dealing with management of projects (Winch 2002). Its well established tools and techniques have assisted project managers in monitoring the current status measurements against the intended values at any point in time during the course of the project. However, in dealing with construction projects, many variables contribute to the projects' status. Most construction projects involve high degree of complexity, uncertainty and dynamics that may result in increased difficulties in managing these projects (Nguyen et al. 2004). These are usually exacerbated by continuous demands

[2] m.sutrisna@salford.ac.uk

for various requirements including in speed, cost and quality control, health and safety, and so on, that further contributes to a vast increase in their complexity (Gidado 1996). Work progressing on a number of activities simultaneously has made them more difficult to monitor and review due to its multidimensional nature (Burke 2006). Thus many project managers may find it increasingly difficult to monitor and measure the true interpretation of the current status of their projects. Actual status can be measured, but not without potential inaccuracy and time delays. The desired status is also a subject to continuous changes as the project progresses and plans continuously evolving as a part of the dynamics. Regarded as a project management technique that embodies the most fundamental principles of project management in practice, the Earned Value Management (EVM) method has been considered a robust tool to help project managers in dealing with such complexity and dynamics.

In Spain, the concept of project management has been reported as slowly accepted and implemented (Pellicer and Victory 2006). Project management has been considered practically non-existence in the public sector (mainly in its construction) and slowly introduced into the private sector. Taking into account the importance of the construction industry to the Spanish economy and the pace of convergence of practice in Europe and the world, there is a major need for Spanish construction industry to further incorporate project management to improve its practices. Thus, adapting EVM in the Spanish construction industry can be perceived as an important milestone to bring the industry up to speed in the context of project management which will increase its competitiveness in the world. In an attempt of doing so, a research project has been set and hosted by the Department of Construction Engineering, Universitat Politécnica de Valencia in Spain. The aim of the research project is to investigate the potential introduction of EVM in the Spanish construction industry. The research project intends to study the contractors in the Spanish construction industry with the view to introduce EVM to the industry. In order to satisfy the aim, the following objectives have been set:

- to explore the appropriateness of adapting EVM in the Spanish construction industry,
- to analyse the readiness of the firms, human resources and infrastructure (including legislation).
- to recommend the most optimum but realistic way to adapt EVM in the contracting firms operating in the Spanish construction industry

EVM AND THE SPANISH CONSTRUCTION INDUSTRY

Earned Value Management (EVM) was originally developed in the United States during 1960s and has becoming one of the standard tools in the project management field. The Project Management Institute defines Earned Value Management (EVM) as “a management methodology for integrating scope, schedule, and resources, and for objectively measuring project performance and progress”. Performance is measured by determining the budgeted cost of the work performed (i.e. earned value) and comparing it to the actual cost of the work performed (i.e. actual cost). Progress is measured by comparing the earned value to the planned value (PMI, 2004, p. 359). EVM is implemented by establishing the budget, progress to be achieved in relation to the budget and the actual cost incurred in the project. By a constant comparison of these variables, cost and schedule variances can be monitored as well as the schedule performance index and cost performance index. Subsequently, the estimation

completion date, estimation completion cost and cost to complete can be calculated. Further details on the mechanics of EVM, its calculation further development can be found in various relevant textbooks and articles (e.g. Vanhoucke 2012, Anbari 2003, Brandon 1998).

By 1990s, EVM has been widely adopted in the United States, particularly in the defence and aerospace industries. The Department of Defence in the United States for instance, has been active in both promoting and requiring the use of EVM on its projects (Fleming and Koppelman, 2005). However, it became evident that the capabilities of EVM in managing and controlling projects has also been realised in other parts of the world. A survey (NAO, 2005) reported that EVM is mandatory for large projects not only in the USA, but also in Australia and Europe (particularly in Sweden and the UK). As a part of European Union, Spain and its construction industry is tightly linked with the rest of the Europe. Prior to the global financial crisis, the construction industry has been considered one of the most dynamic sectors of the Spanish economy. In 2007, the value of construction domestic output in nominal terms reached € 199,300 M and provided work for approximately 2.6 million workers (about 14% of the country's work force). The importance of the construction industry in Spain relative to the European Union zone can be illustrated by the significant proportion of Spanish construction industry as a percentage of GDP in comparison to other EU countries as follows (SEOPAN, 2007): Ireland (19.2%), Spain, (17.9%), Portugal 15.6%, Finland (14.6%), Netherlands (12.9%), Italy (12.7%), France (10.9%), Germany (10.2%), or the UK (10.5%). This shows that Spain is one of the largest European construction markets. Therefore, improvement in its construction industry will benefit the country in a large scale.

In Spain, the concept of project management has been reported as practically non-existence in the public sector (mainly construction) and slowly but painfully, trying to introduce itself into the private sector (Pellicer and Victory, 2006). The main issues in the Spanish construction industry include inadequate prequalification system, insufficient training, political considerations prevailing over real needs and an insufficient PM maturity (de la Cruz et al. 2006). This is made worse by the more 'traditional' management styles of Spanish managers that count on ad-hoc approaches and generally discard planning (Aram and Walochik 1997). In terms of the lower level of project management maturity in the Spanish construction industry for example, EVM can be seen as a potential way of improvement. Development of an integrated performance management baseline, such as EVM, will require a cultural change (Christensen 1998) to upgrade the project management maturity level in any organisations. This upgrade has been claimed as a way of achieving further competitive advantage (Jugdev and Thomas 2002). As EVM embodies the most fundamental principles of project management in practice, adapting EVM in the Spanish Construction Industry can be regarded as taking an important milestone to upgrade the industry in the context of project management which should increase its competitiveness in the world.

RESEARCH METHODOLOGY

In achieving the research aim and objectives, the overall research methodology in this research has been designed based on mixed methods approach with only the quantitative part (questionnaire) reported in this paper. Following a strong suggestion

within the research community that research, both quantitative and qualitative, is best thought of as complementary (Onwuegbuzie and Leech 2005), this mixed approach is adapted here with the view to explain a phenomenon from different angles. Informed by the literature review, questionnaire survey and follow up interviews involving construction project management practitioners in the Spanish construction industry have been selected to facilitate data collection in this research. In line with the aim and objectives of this research, the questions in the questionnaire were designed to capture the state of art of project management implementation in the Spanish construction industry as well as to investigate the readiness of the Spanish construction companies to implement EVM based on their current practices and capabilities. Follow up semi-structured interviews with senior project managers in the Spanish construction industry were planned to further explore the readiness of the firms, human resources and infrastructure aiming to explore potential scenarios of the most optimum but realistic way to adapt EVM in the Spanish construction industry. As earlier mentioned, the questionnaire survey and its initial findings are the focus of this paper and are discussed in the subsequent sections.

THE QUESTIONNAIRE SURVEY

The questionnaire technique can be defined as a general term including all techniques of data collection in which each respondent is asked to respond to the same set of questions in a predetermined order (deVaus 1996). A semi structured questionnaire combining Likert scale and ranking order with additional feedback spaces was designed for this research. Due to the exploratory nature of the investigation (not yet to generalise), the respondents were targeted with purposive sampling method implementing snowballing technique as described in Robson (2003). The targeted respondents are practitioners involved with managing construction projects in Spain for at least 5 years and involved in previous research conducted by the university. They have been involved with various construction projects in different regions of Spain with a majority of them are working for national and multinational construction companies in Spain. The number of the targeted respondents was sixty project managers. The questionnaire were originally designed in English but translated into Spanish language for clarity and practical reasons. 56 completed questionnaires were received. The characteristics of the respondents are provided in Table 1.

Table 1. Characteristics of the respondents

Number of responses analysed		56
Respondents' work position	Chief Executive Officer	5.35%
	Head of Department	39.28%
	Construction Site Manager	57.14%
	N/A	7.14%
Respondents' experience in construction (in years)	Min	5
	Max	31
	Median	14
	Mean	13

FINDINGS SO FAR

The findings from initial screening of the questionnaire survey can be generally grouped into two different categories, namely project management implementation in

the Spanish construction industry and readiness of construction firms in Spain to adopt EVM. Each of them is discussed in the subsequent subsections.

Project Management Implementation in the Spanish Construction Industry
Majority of the respondents (65.45%) did not consider project management concepts as novelties and, in fact, it is considered as a widely accepted concept in the Spanish construction industry. However, they also indicated that project management tools and techniques are only popular or used in certain construction companies. This is a classical symptom that has been found in other construction industries. Bennet (1983) when studying project management in the UK construction industry reported that although the essential requirements of managing tasks in construction projects were reasonably well understood, they were not widely applied in the UK construction industry or elsewhere. The formalisation of project management as a discipline with its particular techniques and tools was originally initiated and developed in the United States. Thus, their adoption in other countries may not be straightforward due to the potential differences in the industry's infrastructure, regulations or culture. In the case of Spanish construction industry, Pellicer and Victory (2006) even described project management as practically non existence in the industry. The awareness identified here, however, potentially provides a useful platform for any attempts to widening the implementation of project management in the future.

The focus of project management in the Spanish construction industry was found to be the cost which was ranked the 1st by majority of respondents and far outranked other areas including time, quality, health and safety, sustainability, client satisfaction and personal/public relations. Thus, most efforts in managing construction projects in Spain appeared to be dominated by cost controlling and, as indicated by Aram and Walochik (1997), it was typically done in a more reactive and ad-hoc manner. Potential dangers of this approach involve inefficiency, false economy and loss of opportunity to take meaningful actions in later stages of construction projects. Contemporary project management practices witnessed various attempts that have been made in overcoming the perceived inadequacies of classical dimensions such as cost, time and quality (Yu et al. 2005). For instance, other dimensions may have impact on long term reputation of the contracting firm and their chance for repeat businesses. Projects are no longer seen as one-off ventures but also as building blocks in the formulation and execution of corporate strategy which contribute to organisational success in terms of competitive positioning in the global marketplace (Dinsmore 1998). Accordingly, majority of the respondents (63.63%) concurred that there is a need for further use and application of project management tools and techniques in the Spanish construction industry. Considering the converging tendencies to use of EVM in the world, this has opened up the potential for EVM to be introduced and implemented in the Spanish construction industry as an important milestone to upgrade the project management practices in the industry with the view to increase its competitiveness in the world.

Readiness of Construction Firms in Spain to Adopt EVM
This part of the questionnaire explores the existing practices relevant to the collection of information required to implement EVM. Majority of respondents (80%) confirmed the use of a certain levels of Work Breakdown Structure (WBS) in the construction programme (schedule) in Spain during earlier phases of the project, i.e. pre-tender in estimating the project cost. However, they also informed that the

estimation of the project cost is mainly based on the quantity estimated which may not necessarily linked to the activities in the WBS or to the programme (schedule). WBS has been regarded a crucial tool in integrating schedule and cost information (Jong and Woo 2004). Thus, there appears to be a gradually looser relationship between the schedule and cost information as construction projects progress in Spain. 'New' construction schedules were developed based on the actual works requirement just before and during the construction phases using the quantity and amounts of money specified in the granted tenders as guidelines. This looser relationship between the schedule and cost information may pose a potential difficulties in implementing EVM into their practices as EVM requires exactly that for the determination of the planned values to be used as the baseline. Consequently, a 'success' in implementing EVM in the Spanish construction industry would also mean an improvement to their project management practices by further integrating the schedule and cost information.

Majority of the respondents (65.45%) informed that the tracking of projects' progress in the Spanish construction industry is typically done using the record of project expenditure (actual cost/expenses) so far. This can be considered a more 'traditional' project management practice that embodies what exactly EVM is moving away from. By segregating the earned value (progress to be achieved in relation to the budget) from the actual cost (actual expenditure to date), EVM provides a more accurate representation of the progress achieved in the project as measuring progress using expenditure can be misleading in many cases. Thus, this separation can be considered one of the fundamental advancements in the way of thinking in project management offered by EVM. Implementing EVM in such an environment will require shifting the mind set of the practitioners in the industry to appreciate the benefits and not perceiving EVM simply as additional tasks to them and a further monitoring/scrutiny from top management of individual performances. This internal resistance have been well documented and reported in literature as one of the main challenges in implementing EVM in an organisation (e.g. Bower 2007, Antvik 1998, Thamhain, 1998).

From the initial analysis, it became evident that the readiness in the Spanish construction industry to implement EVM is not very high, mainly due to the lower project management maturity level of many construction companies in Spain. The different levels of project management maturity portray a firm's evolution from immature project management practices to solid practices and the related infrastructure necessary to support projects at an organisational level. Following the definition of various project maturity levels described in Ibbs and Kwak (2000), this can be indicated as level 1 (ad-hoc) for small and medium construction companies and level 2 (planned) for large construction companies. However, more in-depth investigation is needed to draw a more accurate picture of the project management maturity level and readiness to implement EVM in the Spanish construction industry.

CONCLUSIONS AND FURTHER RESEARCH

Whilst becoming one of the 'standard' tools in the project management field, EVM has been adopted in many countries beyond its birth place in the United States. Meanwhile, the Spanish construction industry has been considered slow in utilising project management. Taking into account the convergence of practices and standarization in the world, there is a need for the Spanish construction industry to

accelerate the absorption process of project management concept, tools and techniques in its practices to improve its competitiveness. EVM has been considered the most suitable project management tool to achieve that. From the initial analysis of a survey involving practitioners in the Spanish construction industry, various potential barriers and enablers of implementing EVM in the industry have been identified and reported here paving path for the next stages of the investigation to take place. More in-depth analysis of the dataset as well as the outcome of follow-up interviews with practitioners will be reported in subsequent dissemination of this research project.

ACKNOWLEDGMENTS

This research was partially supported by the Universitat Politècnica de València that funded a two-month visitorship for Professor Sutrisna. The authors are also indebted to all the participants in the survey and in the interviews.

EXPLORING MULTI-PROJECT MANAGEMENT IN CONSTRUCTION CONTRACTOR ORGANISATIONS

George Hagan[1] Denise Bower[2] and Nigel Smith[3]

[1,2,3]*Institute of Resilient Infrastructure, School of Civil Engineering, University of Leeds, Leeds, LS2 9JT, UK*

ABSTRACT

Contractor organizations find themselves grappling with increasing complex projects and programmes, in the face of more demanding customer requirements, rapid technological advances, confusing stakeholder relationships, challenging and acute supply situations and an unending quest for improved performance. Parallel to this, there is increasing acceptance that programme management is the vehicle for achieving both organisational strategic objectives and aligning projects to overall strategy of the organization. Based on an empirical study and literature on programme management, the current reality of construction contractors' multi-project management is explored. The study reveals that contrary to the view that multi-project management must be applied in multi-project environments, Construction Contractors' in the main still apply single project management approach in delivering multi-projects. The paper identifies the barriers to contractor programme management and proposes that a framework for multi-project management in contractor outfit should include context. It concludes that understanding the environment Contractors' operate in will provide the first step to developing an approach that can deliver in a multi-project environment rather than utilising the single project paradigm. This will shift the focus from how best to deliver every single project as if they stand alone, to how effectively and efficiently multiple projects can be managed.

Keywords: contractor, framework, multi-project management, programme.

INTRODUCTION

Construction contractors usually have a number of projects going on simultaneously and therefore operate in a multi-project environment. Increasingly, projects are also procured through integrated routes which are complex and place greater responsibilities on contractors. Such responsibilities include dealing with unending client requirements, rapid technological advances, confusing stakeholder relationships, challenging and acute supply chain situations and unending quest for improved performance. The multi-project environment is also characterized by dependencies and interrelationships among projects being delivered simultaneously and within elements of any particular project system. There is however very little research on multi-project settings especially in construction, even though multi-

[1] g.n.hagan01@leeds.ac.uk
[2] D.A.Bower@leeds.ac.uk
[3]N.J.Smith@leeds.ac.uk

project context and temporary systems are extensively common in contemporary business (Engwall and Jerbrant, 2003, Artto et al., 2009, Aritua et al., 2009). Notwithstanding the lack of multi-project context in research, programme management is increasingly accepted as the vehicle for effective delivery of multi-projects in achieving both organisational strategic objectives and aligning projects to overall strategy of the organization. This paper is a study of the actual management practices of construction contractors operating in such multi-project environment. The study reviews programme management literature to identify the key themes expounded as essential in multi-project management. Based on the empirical study and the key themes in literature, an analysis is carried out to identify the barriers to contractor programme management and a proposed solution to manage multi-projects.

The data for the study was gathered from five major construction companies in the UK. Data information was collected using semi-structured interviews of management level practitioners of these organisations. The research reveals that contrary to the view that multi-project management must be applied in multi-project environments, Construction Contractors' in the main still apply single project management approach in delivering projects. It concludes that understanding the environment Contractors' operate in, will provide the first step to developing an approach that can deliver in a multi-project environment rather than utilising the single project paradigm.

PROGRAMME MANAGEMENT

Managing single projects is fundamentally different to that of multiple projects. Mainstream literature in project management has been dominated by single project management approach as if organisations execute one or more projects independently or as loosely interdependent projects (Sacks, 2004). Managing projects in a multi-project environment is concerned with dealing with issues wider than in a single project environment. The generic principles within project management as applied across different disciplines as if "one size fits all" has therefore been identified as one reason for project failures (Maylor et al., 2006, Winter et al., 2006). To address the problem of using project management approach to manage multiple projects, programme management has increasingly been accepted as the preferred approach for providing a structured means of aligning, coordinating and managing a portfolio of construction projects to deliver benefits that would not have been achievable if the projects were managed independently (Lycett et al., 2004, Pellegrinelli et al., 2007, Reiss, 2003).

Approaches to programme management have been presented in variety of ways in literature by different authors (OGC, 2011, PMI, 2006, Reiss, 2003). According to Gray (1997) it is the integrated approach capable of streamlining the effective delivery of projects. In the UK, the publications by Office of Government Commerce (OGC) of *Managing Successful Programmes* (MSP) in 1999 and regular revised editions since then, has promoted programme management as the preferred approach for managing multi-projects in the public sector (OGC, 2011). Whilst there has not yet emerged an approach which is universally acceptable for programme management, there seems to be agreement that its use provides benefits which will not be if project management approach is adopted (OGC, 2011, Pellegrinelli, 2011, PMI, 2006). According to PMI (2006), managing multi-projects by means of programme management allows for integrated deliverables across the programme. MSP attributes to programme management, a framework that integrates and reconciles competing resource demands for the projects of the programme (OGC, 2011). The adoption of

programme management approach has also been proposed as that which allows for the application of broad management themes to help ensure the successful delivery of the programme. These themes are widely agreed by writers to be benefits management, stakeholder management and programme governance (OGC, 2011, Pellegrinelli et al., 2007, PMI, 2006).

The adoption of programme management approach for the delivery of multi-projects has been argued to provide the following advantages:

- Bringing about planned change, implementation of strategy and management of complex information systems (Pellegrinelli et al., 2007, Ribbers and Schoo, 2002)
- Aligning, coordinating and managing portfolio of projects to deliver value which would have been impossible had the projects been managed independently (Maylor et al., 2006, Partington et al., 2005)
- Improves the management of projects in isolation, especially in multi-project environment and where projects integration in terms of both development and deliverables is a critical success factor (Pellegrinelli, 1997)
- Provides the approach for dealing with issues such as lack of coordination and control which affect effective and efficient delivery of multiple projects (Lycett et al., 2004).

In summary, research and literature present programme management as the preferred approach when managing multi-projects. There is no universally acceptable framework for programme management but there is agreement in the benefits to be derived if programme management approach is adopted appropriately and not as a scaled-up project management. Furthermore, there is agreement that programme management approach allows for application of key themes such as benefits management; stakeholder management and programme governance to ensure effective multi-project delivery.

The research objective

The research from which this paper emanates investigates how construction contractors manage complex projects in multi-project environments. This paper is based on part of the investigation that sought to explore the management of multi-projects in construction contractor organisations. The aim is to study actual multi-project management from the perspective of the construction industry contractors with a view to grounding and enriching existing theoretical and conceptual frameworks. To be able to carry out the research, an appropriate methodology is essential. In order to fulfil the aim of the study, a multiple case study approach was adopted for the investigation. This methodology is preferred because: it allows the research investigation to be carried out in context; allows an in-depth understanding of project complexity in a real-life setting; and also allows empirical and in-depth use of different combinations of data collection which were not identified in literature (Yin, 2009). Five organisations with long term experience in managing complex multi-projects were involved in the study which provided access to the projects they were undertaking.

Research design

In order to explore the management of multi-projects in the organisations participating in the research, the questions asked were:

- *How do you manage multi-projects in your organisation?*

- *What management approaches, arrangements, framework and/or practices are employed in managing multiple projects?*

The aim was to obtain data from multiple sources on actual practices on the five construction contractor organisations and create succinct case summaries using a common format to facilitate both in-case and comparative analysis across the five cases. The organisations were private firms based in the UK and providing construction services both on national and international fronts across Europe and Asia. The multi-projects investigated included hospitals, schools, roads, hotels and a wind farm.

The empirical data was collected using semi-structured interviews. An outline interview and data collection protocol was developed summarising key questions and areas of interest for observation or investigation. The intention was to build as comprehensive as possible a picture of the functioning of the participating organisations. In particular, the protocol was designed to find out how those involved in multi-project delivery used multi-project (including programme) management principles and whether they were aware of such principles. The research entailed semi-structured interviews with multiple participants in relation to each multi-project, spanning a period of three to six months.

The participants were practitioners with long experience in managing multi-projects within the construction industry and included chief executives, managing directors, programme directors, project directors and managers, planners, design director, commercial director and human resource manager. In addition, documentary information on specific practices adopted for the projects was analysed. The information gathered included organisational charts, annual reports stating organisations objectives, press releases concerning the projects or an influential area, general public literature describing the organisation and its business, statements of strategy, selected presentations, process descriptions, performance related and monthly reports, schedules, plans and drawings.

The interview sessions were recorded with the permission of the interviewees, transcribed and coded. Interviews were usually between an hour and two. The coding was formed into clusters of contextual areas so that relationships that otherwise would not have been clear was brought out. Actual practices and approaches were identified from the interview transcripts and observation notes and subsequently mapped out against multi-project themes for review. The data was continually linked to existing theory and body of knowledge of programme management, as well as the wider theoretical context of the management of project-based within an organisation as a whole. The initial findings are presented below.

Research findings

This section presents the key research findings of actual practices of construction contractor organisations in relation to existing theoretical literature and body of knowledge on programme management.

Table 1 gives a summary of the findings in relation to benefits management which is considered a key theme essential to programme management. According to literature benefits management is central to programme management in the delivery of benefits. Benefits are achieved through project outputs which builds capabilities and translates into outcomes for the benefit of the organisation (OGC, 2011). Managing benefits includes identifying likely benefits through engagement with stakeholders and establishment of supporting structures and processes to help with the assessment, quantification, impact analysis and assignment of responsibility and accountability.

The table reveals that these critical benefits management determinants are not vigorously pursued by the organisations. The data analysis shows that construction contractors in the main consider managing multi-projects as business-as-usual and therefore do not consider the use of programme or portfolio management to be of any particular benefit to them.

Organisation	Main themes
	Benefits management
Contractor A	• No individual with sole responsibility for benefits management. Benefits measured in terms of profitability.
Contractor B	• Benefits only considered from individual projects perspective and no formal linkages among projects.
Contractor C	• Benefits management not a recognisable theme pursued within organisation, although individual projects are expected to deliver financial benefits.
Contractor D	• No standardized approach to benefits management. Each project is considered on its own merit to deliver best value.
Contractor E	• Expected benefits set out at tender stage and evaluated monthly, comparing forecast values against actual values realised. Benefits are calculated in monetary terms only.

Table 1 – Benefits management in Contractor organisation

Projects are managed as if they stand alone purely for delivery purposes to derive maximum benefits from each and every project, even if the projects are procured as a bundle. According to one case organisation, *"we are much better off actually having our teams focusing on delivering on the one job, than worrying about the complexity of the programme or portfolio".* Another said *"Well to be quiet honest, I think in construction, if people and companies were more focused on individual stand alone projects rather than what the integration brings, they will be more successful".* Stakeholder management requires considering the interest and concerns of stakeholders to ensure successful programme delivery. It involves identifying and assessing stakeholder needs in order to meet their requirements and improve relations (PMI, 2006).

Organisation	Main themes
	Stakeholder and leadership
Contractor A	• Identification of stakeholders carried out and analysed. Structures put in place for dealing with stakeholder issues.
Contractor B	• Formal identification and analysis carried out and responsibility for dealing with stakeholders assigned to programme leader.
Contractor C	• Stakeholders are analysed to understand what they want and approach tailored to meet their needs. Recognition of interdependence of meeting stakeholder requirements and organizational goals are drawn.
Contractor D	• Formal approach for identification, analysis and managing stakeholders' non existent.
Contractor E	• Regular meetings with stakeholders to address concerns and improve relationships. Formal communication lines exist for addressing issues.

Table 2 - Stakeholder management in contractor organisations

The research revealed that the organisations investigated embraced stakeholder management fully and had structures and processes in place for identification and analysis of stakeholders (Table 2). The importance of stakeholder management is understood by these organisations by recognising their interdependence and the need to address their interest and concerns.
The organisational structures, processes and governance are set up for delivering individual projects or programmes in the organisations studied. Moreover, in the case organisations, it was considered essential to organize for projects specific responsibilities and roles for effective management delivery. Organisational structures, procedures and policies (Table 3) were both generic in terms of core processes and procedures and specific structures for meeting varying demands and services.

Organisation	Main themes
Contractor A Contractor B Contractor C Contractor D Contractor E	Programme Governance • Cross project issues are managed at programme level and solutions found to benefit programme rather than any particular project. • Same tools and control are used for individual projects and programme. • Strategic alignment of programme evident. • Organisational processes and procedures for managing programme are the same for all other projects too. No distinction made. • Programme has an executive board that meets monthly to evaluate progress and agree plans for the future.

Table 3 - Programme governance in contractor organisations

The analysis also highlighted the following general observation as important for construction contractor organisations engaged in multi-project management:

- The organisations business strategy must be aligned to the projects they tender and subsequently deliver. This alignment is best achieved at the very early phases
- Organisations investigated considered benefits in terms of their functional effectiveness which can be translated or evaluated in financial terms, although intangible benefits such as stakeholder satisfaction were also essential
- In all organisations, risk management tend to be most essential and central to their businesses.

The study further revealed the following barriers to contractor programme management approach:

- Construction contractors consider project management as business-as-usual. Adopting approaches such as programme or portfolio management are viewed as unnecessary since there are no proven results to back their benefits
- Unlike clients who intentionally package projects in order to derive benefits that would not have been if they had been procured individually, the construction contractors studied believe that they derive better value when projects are delivered individually than when multi-project approach is adopted
- Construction organisations mostly have core processes, procedures and tools for managing all their projects. Such processes also indicate “how we work” and cannot easily be adapted to suit changing environment within the industry.

Finally, it was found that construction contractors only apply selected elements of the key programme management themes when delivering multi-projects. Project management tools and processes were applied in managing multi-projects. The reason for this can be attributed to the fact that single project management philosophy is ingrained in such organisations applied and only scaled-up when managing multi-projects. To overcome these barriers, construction organisations need to accept that there are differences between projects and programmes and applying the same delivery approach will not yield effective results. Programme management standards tend to focus mainly on processes and underplay the context in which construction contractors undertake their business. Incorporating the contractor's environment to demonstrate how benefits will be derived not only for stakeholders but also the contractor organisation will be the right approach to gain acceptance.

CONCLUSIONS

The paper explores the management of multi-projects in construction contractor organisations. It describes the essential themes of programme management as benefits management, stakeholder management and programme governance. By employing case study approach, the study uses empirical data from five construction contractor organisations to demonstrate that contrary to the view that multi-project management should be applied in a multi-project environment, construction contractors still apply single project management approach to deliver multi-projects. The study found that contractors only apply certain elements of the key themes for programme management in delivering multi-projects.

It also found that including context in multi-project management which recognises the construction contractor's environment will help its acceptance and use. It will also be possible to demonstrate the benefits to be derived in applying programme management approach to managing multi-projects. This in turn will shift the focus from how best to deliver single projects as if they stand alone to how effectively and efficiently multi-projects can be managed to derive benefits.

FACTORS INFLUENCING ENTREPRENEURIAL INTENTIONS OF BUILT ENVIRONMENT STUDENTS IN SOUTH-WEST NIGERIA.

Patience Fikiemo Tunji – Olayeni [1] and Philip Olayemi Lawal[2]

[1]*Department of Building Technology, Covenant University, P.M.B 1023 Ota – Ogun State*

[2]*Department of Quantity Surveying, Caleb University, P.M.B 21238 Ikeja - Lagos*

ABSTRACT

Entrepreneurs from any field of endeavour are boosters of a nation's economy. Built environment professionals play a vital role in the socio-economic development of a country. This study seeks to identify the major factor influencing the entrepreneurial intention of built environment students in south-west, Nigeria. Random sampling technique was adopted to select 210 built environment students from two universities in south-west, Nigeria. The students were of the building, quantity surveying, architecture and estate management programmes. The students responded to a 15-item questionnaire. Descriptive and inferential statistics were used to analyse the data collected. The findings revealed that perceived behavioural control has the greatest influence on entrepreneurial intention of built environment students. The study concludes that more skill and knowledge of entrepreneurship would boost perceived behavioural control of students towards entrepreneurial activities. Therefore, institutions of higher learning should incorporate more entrepreneurship studies in their curriculum so that most students can have a positive perception and intention towards entrepreneurship. Also the government should provide counselling services and financial incentives to graduates who are interested in entrepreneurship.

Keywords: built environment, entrepreneurial intent, entrepreneurs, nigeria, students.

INTRODUCTION

Construction activities are an index of the economic and social progress of a country (Ogunlana, et al. 2003). In order to achieve economic and social progress Nigeria will require more houses for living; hospitals and health centers for health care services; schools, colleges, polytechnics and universities for education; banks, shopping malls, factories, civil buildings; clubs, theatres and cinemas for recreation; churches and mosques for worship (Bala 2011). The design and construction of these facilities is the responsibility of built environment professionals (consultants and builders).

[1] Pat.tunji-olayeni@covenantuniversity.edu.ng
[2] lawal@calebuniversity.edu.ng

Entrepreneurs from any field of endeavour are boosters of the economy. They play a more vital role in developing countries because they create jobs, increase productivity, spur innovation and grow the economy (Ogundele 2007; Omeje 2008).

The Nigerian government has among other mandates to create five million jobs annually within the next three years, establish more skills acquisition centers and implement the local content policy in all sectors, in order to boost job creation in the country. The existing educational system in Nigeria can influence the development of entrepreneurial skills. This is because the academic context is an important environment that impact's on an individual's entrepreneurial tendencies (Franke and Luthje 2004).

However, in times past entrepreneurship was considered a subject for students with a predominantly business background more than any other. Nowadays, the subject of entrepreneurship is gaining much ground even among other disciplines with non-business background (Edwards, et al. 2009). This is because all students have and can develop a set of skills that can make them suitable for creating jobs for themselves and others.

Given the vital role of built environment professionals in the socio-economic development of a country and the benefits of entrepreneurs to nation building, this study seeks to identify the major factor influencing the entrepreneurial intention of built environment students in south-west, Nigeria. It also seeks to determine if there are any significant differences between the entrepreneurial intention of built environment students and their demographic statistics namely: gender, programme type and institution type.

THEORETICAL FRAMEWORK

Theories of Entrepreneurship

Cunningham and Lischeron (1991) identified six major schools of thought on entrepreneurship namely: the great person school, the psychological characteristics school, the classical school, the management school, the leadership school and the intrapreneurship school. Proponents of the great person school (Schumpeter 1934; Schultz 1975) are of the opinion that entrepreneurs are born and not made. They believe that entrepreneurs possess certain characteristics such as energy and persistence that differentiate them from non-entrepreneurs. In the psychological characteristics school, proponents like (Gartner 1989) view entrepreneurs as individuals who possess unique values, attitudes and needs, which drive them. This thought also encompasses the theories of entrepreneurial events (Shapero and Sokol 1982) and planned behavior (Ajzen 1991). The entrepreneurial events theory is based on the fact that entrepreneurial intention is influenced by certain situational context like personal characteristics, perceptions, beliefs, values, background and environment. While the theory of planned behavior is based on the belief that actions are preceded by conscious decisions to act in a certain way (Ajzen 1991). Proponents of the classical school such as (Drucker 1985) believe that innovation is the central theme of entrepreneurship. The management school opines that entrepreneurs are persons who organize, own, manage and assume the risk of an economic venture (Cunningham and Lischeron 1991). The leadership school posits that entrepreneurs are leaders who are able to adapt their style to the needs of people (Cunningham and Lischeron 1991). Proponents of the intrapreneurship school (Timmons 1999; Carrier

1996) believe that entrepreneurial skills can be useful in various organizations through the development of independent units to create market and expand services.

Entrepreneurial Intention

Entrepreneurial intention is the state of mind directing a person's attention towards self- employment as opposed to organizational employment (Bird, 1998). It can be used to predict students' involvement in entrepreneurship and why they decide to venture into business (Ariff, et al. 2010). Shapero and Sokol (1982) and Ajzen (1991) both viewed entrepreneurship from a psychological point of view. Shapero and Sokol (1982) advanced the entrepreneurial events theory. They opined that entrepreneurial intention is influenced by certain situational context like personal characteristics, perceptions, beliefs, values, background and environment. While (Ajzen 1991) belief that actions are preceded by conscious decisions to act in a certain way. He advanced the theory of planned behaviour.

This study would be based on the theory of planned behaviour to explain why built environment students intend to venture into business. This is because the theory of planned behaviour is an intention based model (Ajzen 1991) and is used to explain an individual's intention to perform a given behavior (. Arif, et al. 2010). This theory has been used severally in explaining entrepreneurial intention in a number of studies (Kolvereid 1996; Gird and Bagraim 2008 and Arif, et al. 2010).

Ajzen (1991) explained that intentions were a function of attitudes, social pressures and perceived ease or difficulty of performing the behaviour. He proposed three determinants of intention namely: attitude, subjective norms and perceived behavioural control.

Attitude

According to Ajzen (1987) attitude refers to personal desirability to perform a behavior. It is the degree to which a person has a favourable or unfavourable evaluation or appraisal of the behavior in question (Maalu, et al. 2010). Kolvereid (1996) defines attitude towards entrepreneurship as the personal desirability in becoming an entrepreneurs. This means that high expectations and beliefs towards self-employment reflect a favorable attitude towards entrepreneurship (Arif, et al. 2010).

Subjective Norms

Subjective norm refers to a person's perception of the social pressure endearing one to perform or not to perform a particular behaviour (Ajzen 1987). This determinant of intention is influenced not only by broad cultural attitudes toward entrepreneurship, but also the attitudes of particular individuals, groups and networks the person is most influenced by such as family, friends, peers and significant others (Maalu, et al. 2010).

Perceived Behavioral Control

Perceived behavioural control is the perceived ability to execute target behaviour (Ajzen 1987). It is the ease or difficulty of performing the behaviour and it is assumed to reflect past experience, as well as anticipated impediments and obstacles (Maalu, et al. 2010).

 ISBN: 978-1-84219-840-7 .

METHODOLOGY

The descriptive survey research design was adopted for this study. The target population for this study consisted of all final year students in higher institutions in south-west Nigeria. There are four states in south-west Nigeria. Two of the states were randomly selected namely: Lagos and Ogun state. From the two states, two higher institutions were also selected randomly; a university in Ogun state and a polytechnic in Lagos state. Two hundred and ten questionnaires were distributed to built environment students of the two institutions. 132 questionnaires were returned; 68 from Covenant University, Ogun state and 64 from Yaba College of technology, Lagos state. The questionnaire which was distributed in January 2012 was divided into two sections. The first section measured factors influencing entrepreneurial intention of students. A likert scale ranging from 1 (strongly disagree) to 5 (strongly disagree) was used to measure attitude towards entrepreneurship, subjective norms and perceived behavioural control. Demographic information of the students was gathered in the second section of the questionnaire. The constructs for attitude, subjective norms and perceived behavioural control were adapted from (Ariff, et al, 2010).

Data Analyses

Both descriptive and inferential statistics were used to analyze the data obtained for this study. Chi-Square independence test was employed to measure significant difference in the entrepreneurial intention of built environment students based on their demographic statistics of (gender, institution type and programme).

Table 1 Response Rate of respondents

Covenant University	Building	Architecture	Estate Management	Quantity Surveying	Total
No. Distributed	30	30	30	-	90
No. Received	21	25	22	-	68
Yaba College of Tech					
No. Distributed	30	30	30	30	120
No. Received	12	22	15	15	64

Two hundred and ten questionnaires were distributed to Building, Architecture, Estate Management and Quantity Surveying students of Covenant University and Yaba College of Technology. Covenant University does not offer Quantity Surveying programme. Of the all the questionnaires distributed sixty – eight students from Covenant University filled and returned the questionnaire and sixty – four students from Yaba College of Technology also filled and returned the questionnaire.

Table 2 Demographic profile of respondents

Variable	Frequency	Percentage
Gender		
Male	76	57.60
Female	56	42.40
Total	132	100
Institution		
University	68	51.50
Polytechnic	64	48.50
Total	132	100

Programme		
Building	33	25.0
Quantity Surveying	15	11.40
Architecture	47	35.60
Estate Management	37	28.00
Total	132	100

Of all the students that participated in the study 76 (57.60%) were male, 56 (42.40%) were female; 68 (51.5%) were from the University, 64 (48.5%) were from the Polytechnic; 33 (25%) were from Building, 15 (11.40%) were from Quantity Surveying, 47 (35.60%) were from Architecture and 37 (28%) were from Estate Management.

Results

Table 3 Entrepreneurial Intention of Built Environment Students

Entrepreneurial intention	Frequency	Percentage
Yes	124	93.90
No	8	6.10
Total	132	100

Table 3 reveals that 93.90% of built environment students have a positive intention towards entrepreneurship while only 6.10% have a negative intention towards entrepreneurship.

Table 4 Timing for Entrepreneurship

Timing for entrepreneurship	Frequency	Percentage
Immediately after graduation	19	15.32
3 years after graduation	39	31.45
5 years after graduation	66	53.23
Total	124	100

From table 4 it can be seen that 53.23% of the students who have positive intention towards entrepreneurship intend to start their own businesses five years after graduation. While 31.45% intend to go into entrepreneurship 3 years after graduation. Only 15.32 % of students with positive intention towards entrepreneurship intend to start their businesses immediately after graduation.

Table 5 Factors affecting entrepreneurial intention of built environment students

Factors	N	Mean	Rank
ATTITUDE			
Compensation	132	3.80	10
Self-realisation	132	4.21	3
Independence	132	4.20	4
Power	132	4.11	6
Challenge	132	4.12	5
SUBJECTIVE NORMS			
Family	132	3.89	9
Friends	132	2.16	14
Colleagues	132	1.89	15
Lecturers	132	3.39	11
Important people	132	2.17	13
PERCEIVED BEHAVIORAL CONTROL			

Confidence	132	3.97	7
Ease	132	4.45	1
Education	132	3.95	8
In control	132	2.44	12
Skills and capabilities	132	4.36	2
Valid N (listwise)	132		

Table 5 reveals the factors influencing students' intention towards entrepreneurship. From the table, perceived ease of carrying out entrepreneurial activities has the greatest influence on students' entrepreneurship intention. Perceived skill and capabilities for entrepreneurship has the 2nd influence on students' entrepreneurship intention. These two factors belong to the perceived behavioural control category indicating that perceived behavioural control has the greatest influence on students' entrepreneurial intention. The table also reveals self-realization, independence and power as the 3rd, 4th and 5th factors respectively influencing students' entrepreneurial intention. These three factors belong to the attitude category. This indicates that attitude towards entrepreneurship intention has the next influence on students' entrepreneurial intention. The last three factors; important people, friends and colleagues belong to the subjective norms category indicating that it (subjective norms) has the least influence on built environment students' entrepreneurship intention.

Table 6 Test for significant difference

Chi-Square test

Variable	Pearson chi-square	df	assymp. Sig
Gender	11.558	1	0.001
Programme	8.142	3	0.043
Institution	0.411	1	0.521

The results in table 6 indicate that there is a significant difference in the entrepreneurial intention of built environment students based on their demographic characteristics of gender ($p=0.001<0.05$) and programme ($p=0.044<0.05$). However, there is no significant difference in the entrepreneurial intention of built environment students based on institution type because $p = 0.523>0.05$. This could imply that the entrepreneurial intention of built environment students is similar irrespective of differences in their institution type.

Discussions

The findings of the study reveal that built environment students in south-west Nigeria have positive entrepreneurial intention. This finding is consistent with the findings of Kiadese (2008) and Ariyibi (2006) who found out that tertiary students in Ogun and Lagos states respectively have high inclination towards entrepreneurship. This may be because venturing into a business sometime after graduation is normal for most fresh graduates because they lack experience (Ariff, et al.2010). Moreover, it was discovered from the study that of all the categories of factors influencing entrepreneurial intentions of built environment students in South-West Nigeria, perceived behavioural control has the greatest influence on students' entrepreneurial intention. This finding is similar to the findings of (Ariff, et al. 2010) who discovered that perceived behavioural control had the strongest influence on entrepreneurial intention of Malay students. The study also revealed that there is no significant difference between students' entrepreneurial intention and institution type. This

finding is congruent with the findings of Chenube, Saidu, Omumu and Omomoyesan (2011) who found out that entrepreneurial inclination of university students in Delta state, Nigeria is similar irrespective of the institution type. The study however, discovered a significant difference in the entrepreneurial intention of built environment students based on gender and programme type.

Conclusion

Considering the role of built environment professionals in the economic and social development of a nation and the benefits entrepreneurship can bring to an economy, the study investigated the factors influencing entrepreneurial intention of built environment students in South- West Nigeria. It was found that built environment students in south-west Nigeria generally have a positive intention towards entrepreneurship and most of them believe that perceived behavioural control has the greatest influence on their entrepreneurial intention. Therefore, institutions of higher learning should incorporate more entrepreneurship studies in their curriculum so that most students can have a positive perception and intention towards entrepreneurship. Also the government should provide counselling services and financial incentives to graduates who are interested in entrepreneurship.

KNOWLEDGE MANAGEMENT PRACTICES IN CANADIAN HABITAT FOR HUMANITY AFFILIATES

Anna Perreira[1] and Jeff H. Rankin[2]

[1]*PhD Candidate, Civil Engineering, University of New Brunswick, Canada*

[2]*Professor and M. Patrick Gillin Chair in Construction Engineering and Management, Civil Engineering, University of New Brunswick, Canada*

ABSTRACT

The majority of knowledge management (KM) research in the construction industry has focused efforts on the for-profit sector. This gap is addressed by assessing knowledge management practices (KMPs) in construction non-profit volunteer organisations (CONVOs), specifically investigating Canadian Habitat for Humanity (HFH) affiliates. Preliminary survey results of 27 Canadian HFH CONVOs are presented based on data collected using self-administered questionnaires. Specific objectives of the survey focus on identifying the key performance indicators and critical success factors for KM; identifying various KM tools (IT technologies and non-IT techniques) utilised; and assessing affiliates' knowledge management maturity. A modified general knowledge management maturity model *(G-KMMM)* is used to investigate how these CONVOs manage the knowledge of its essential temporary labour force. Respondents exhibit varying degrees of knowledge management maturity influenced by their organisational size and operational outputs. Survey results are used to identify a focus group for the adoption of KM tools. Through action research principles we aim to determine whether HFH affiliates adopting both IT technologies and non-IT techniques illustrate higher knowledge management maturity compared to non-adopters.

Keywords: habitat for humanity, knowledge management practices, KM tools maturity, survey

INTRODUCTION

The majority of knowledge management (KM) research in the construction industry has focused efforts on the for-profit sector. However, global natural and anthropogenic (human-induced) disasters increasingly affect the built environment in both developed and developing nations and the role of non-profits has never been more vital (Perreira 2011). The provision of shelter solutions by construction non-profit volunteer organisations (CONVOs) has led to hundreds of these unique organisations collaborating with major international alliances such as the United Nations for example. Construction organisations undertake dynamic projects that generate new knowledge for sharing and reuse which is lost as teams disband upon completion of the project (Ribeiro and Ferreira 2010). Volunteers comprise the majority and, in some instances, entire human resources of CONVOs. Therefore the

[1] anna.perreira@unb.ca
[2] rankin@unb.ca

experiences and knowledge created by these volunteers (both internal and external to the CONVO) may be lost as high turnover rates contribute to loss of valuable tacit knowledge. Consequently, opportunities to document lessons learned or best practices and improve future processes to enhance performance are jeopardised (Perreira and Rankin 2011). CONVOs lack the requisite processes and practices essential to knowledge management (KM) since they are also compounded by combinations of fragmented collaboration practice; non-standardise; and poor long term strategising. In addition, Robinson *et al.* (2001) lament that those in the construction industry who have a KM strategy are immature and must secure adequate budgets, time, staff and an IT infrastructure to ensure successful implementation (Al-Ghassani *et al.* 2002).

This research focuses on assessing knowledge management practices (KMPs) in Canadian Habitat for Humanity (HFH) affiliates. Action reaserch (Azhar *et al.* 2010) provides the methodological framework to logically investiage KMPs. The paper reports preliminary results of an *on-going* data collection phase. Currently, sixty nine (69) Canadian HFH CONVOs provide shelter solutions to improverished families through partnerships and demand no down payments or mortage interests, only the total cost of construction. Building operations are dependent on funding from generous sponsors; cooperate donors and volunteer labour from thousands of volunteers, both skilled and unskilled. A pilot test of the survey was conducted using four (4) HFH CONVOs in Atlantic Canada before administering a simple random sample survey to collect data from the remaining population of 65 HFH CONVOs. The survey focused on *identifying the key performance indicators (KPIs)* and *critical success factors (CSFs) for KM*; *identifying various KM tools (IT technologies and non-IT techniques) utilised*; and *assessing affiliates' knowledge management maturity*. A modified general knowledge management maturity model (G-KMMM) (Pee and Kankanhalli 2009) is used to assess each HFH CONVO's KM maturity. The results of the survey are particularly relevant not only to management officials in Canadian HFH CONVOs, but also those in academia and industry practitioners interested in the area of KM.

SURVEY METHODOLOGY

Prior to data collection, a CONVO KM assessment framework was established following gaps' identification in previous research literature (Perreira and Rankin 2011). This framework, a combination of the *construction assessment model (Fayek et al. 2008); principles of total quality management (Deming 1998)* and *construction project phases*, identified the critical success factors (CSFs) for KM in CONVOs and also forms the basis for the development of the research survey instruments. Self-administered questionnaires and interview schedules were developed and pilot tested with six Eastern Canadian HFH CONVOs. Four out of the six CONVOs participated and provided insight on their KM practices which aided the revision of the instruments before administering the survey to the remaining CONVOs. *Figure 1* illustrates a survey design flowchart, where action research (Azhar *et al.* 2010) dictates the workflow highlighting the current diagnosing phase of the research.

A combination of qualitative and quantitative methods was used to collect data from 65 Canadian Habitat for Humanity CONVOs, with a response rate of 46% (27) based on the representative sample size of 59. Data presented in this paper was collected during April 2nd to July 25th from three (3) online self-administer questionnaires using Zoomerang (www.zoomerang.com). Questionnaire 1 collects general respondent and company details, while 2 and 3 collect information on CSFs and KM maturity.

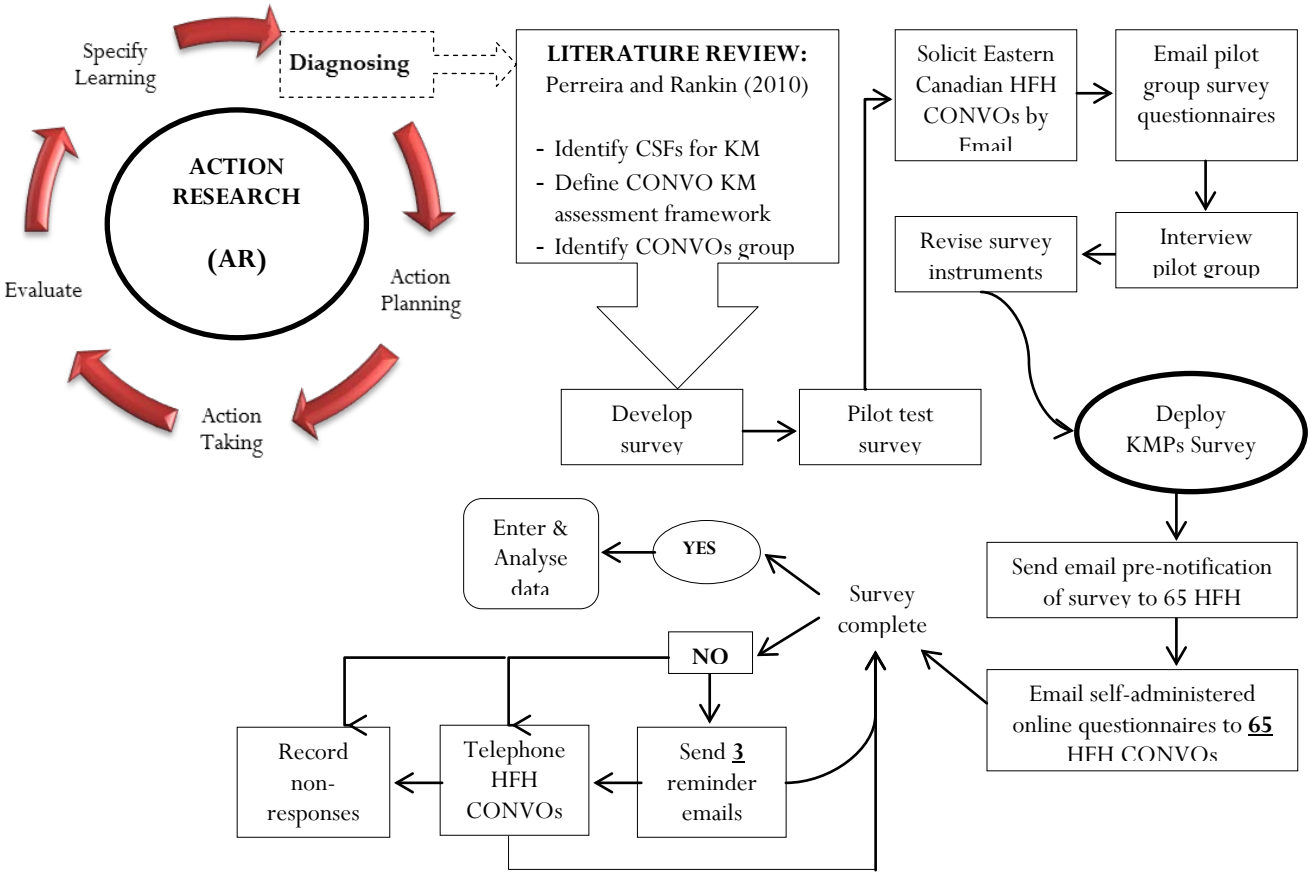

Figure 1: Research survey design flowchart

KMPS IN CANADIAN HFH CONVOS

Table 1, illustrates the company profiles of survey respondents to date classified as large, medium and small urban and regional/rural based on the population centers they serve (HFHC, 2012); average staff and volunteer sizes, age and data on yearly builds. The majority of respondents are company directors. While KM in the construction industry have gained popularity in the United States, Asia, the United Kingdom and other parts of the world, only 42% of Canadian HFH CONVOs survey respondents have heard the term. However 90% agree that both tacit and explicit knowledge are strategic assets to an organisation. Unfortunately, only 19% admit to managing knowledge. In addition, only 74% of respondents have an organisational flowchart yet 48% agree on its effectiveness. Seventy one percent of respondents have no designated knowledge management officer. However, 87% mentioned they have reviewed existing operational manuals to assist their duties but 35% strongly disagreed that dedicated people exist to revise those manuals. Further, only 19% of respondents admit that they regularly compile manuals in the event that they leave the organisation. Figure 2 illustrates how critical the documenting of tacit knowledge is, especially since the level of familiarity of construction aspects varies for project phases. Only 29%, 23% and 32% of respondents are familiar with all aspects pre, during and post construction respectively.

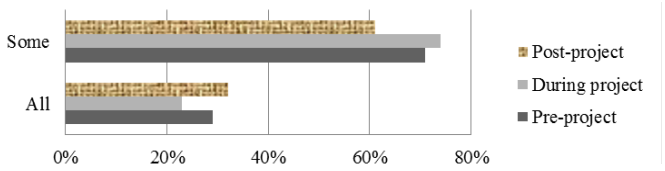

Figure 2: Level of familiarity with construction aspects for each project phase

Table 1: Company profile of survey respondents

Classification	No.	Age (yrs.)	Build Yearly	Position	Staff/yr.	Volunteers/yr.
Large Urban *(541K)*	1	21	Yes	Const. Manager	15-20	> 400
	2	7	Yes	Director	0-5	0-100
	3	9	Sometimes	Director	0-5	> 400
	4	21*	Yes	Director	> 20	> 400
Medium Urban (161–540 K)	5	18	Yes	Director	0-5	200-300
	6	20	Yes	Director	15-20	> 400
	7	19	Yes	Director	5-10	100-200
	8	17	No	Director	0-5	Unsure
	9	12*	Yes	Director	5-10	300-400
	10	24*	Yes	Director	15-20	100-200
	11	18	Sometimes	Director	5-10	0-100
	12	22	Sometimes	Director	5-10	100-200
	13	11*	Sometimes	Director	15-20	> 400
	14	19*	Yes	Director	10-15	> 400
Small Urban *(121-160 K)*	15	25*	Sometimes	Director	10-15	300-400
	16	19	Yes	Director	0-5	0-100

	27	9*	Yes	Director	0-5	100-200

'' connotes companies whose year of establishment and attainment of non-profit status differ*

Critical Success Factors for KM in Canadian HFH CONVOs

Perreira and Rankin (2011) identified four major critical success factors for KM in CONVOs: (i) *knowledge processes (e.g. creation/collection, conversions/analysis, transfer/us and revision/store)*; (ii) *KM systems* (e.g. KM tools); (iii) *KM practices (e.g. communities of practices (COPs))*; and (iv) *KM approaches* (e.g. quantitative vs. qualitative) (see Figure 3).

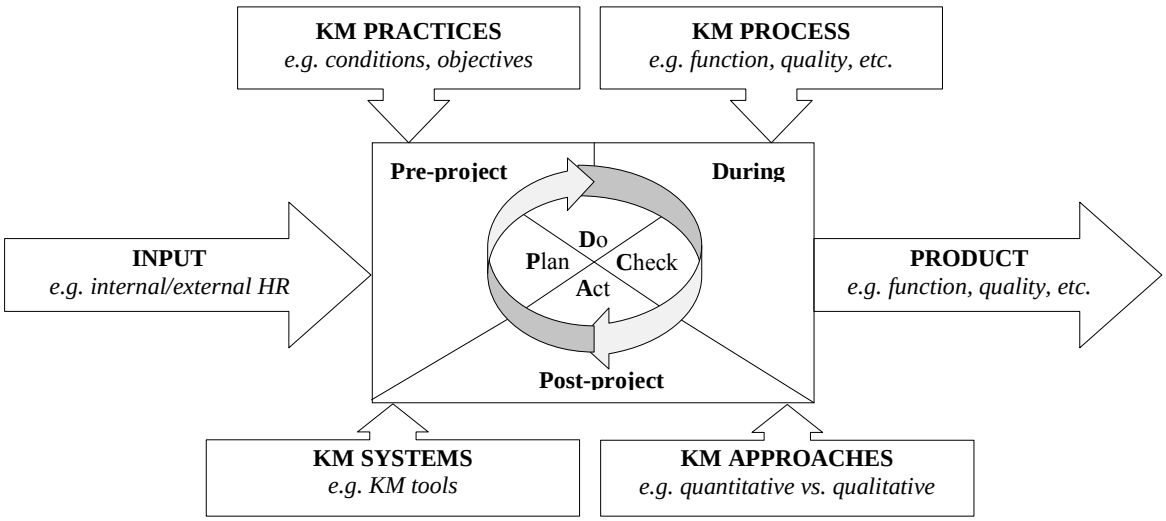

Figure 3: CONVO KM Assessment Framework (adopted from Perreira and Rankin 2011)

Key performance indicators (KPI) were weighted and ranked according to importance. The '*score*' column represents aggregate scores of respondents based on their agreement with KPI statements: *(i.e. strongly agree (5), agree (4), neutral (3), disagree (2) and strongly disagree (1) points).*While the '*impact'* column ranks each KPI based on aggregate perceptions of importance by the respondents. Figure 4 is an example KPI statement:

Please indicate your opinion on the following statements related to PRODUCT TYPE:					
	Strongly Agree	**Agree**	**Neutral**	**Disagree**	**Strongly Disagree**
It is important that I am familiar with all aspects of HFH house designs					

Figure 4: Example of KPI question for CSF Product

Table 2 illustrates a comparison between the aggregate weighted scores *(score*) and ranked perceptions *(impact)* of importance of each KPI for practices and product. Comparison in 'practices' for example, suggests the KPI lesson learn programs (LLPs) as the most important. However, the CSF 'product' has some variation amongst its KPIs. For example, quality is perceived as most important when in actuality function/use is weighted as most critical. This validates not only the internal reliability of the survey but may also suggest a dichotomy between what KPIs and CSFs HFH CONVOs perceive as important verses in actuality those which are most critical.

Table 2: Partial comparison of KPIs for CSFs for KM in Canadian HFH CONVOs

RANK	**PRODUCT**		**PRACTICES**	
	Score	***Impact***	***Score***	***Impact***
1	Function/Use	Quality	LLPs	LLPs
2	Quality	Function/Use	COPs	KM Practices
3	Production	Type	KM Practices	COPs
4	Quantity	Production	Blitz	Blitz
5	Type	Quantity		

KM Tools: Usage and effectiveness

A combination of the first author's work experience with HFHs; a pilot test with four Canadian HFH CONVOs; and Egbu and Botterill's (2002) work influenced the creation of a list of KM tools comprising: *IT (information technology) technologies (both hardware and software)* and *non-IT based techniques*. Respondents were asked to indicate the frequency of usage *(i.e. always =5, often =4, sometimes =3, rarely =2, and never = 1)* and for which knowledge process (i.e. knowledge creation, conversion, transfer and storage) each tool was utilised. In addition to usage, respondents were asked to rank the effectiveness *(i.e. highly effective = 5), effective = 4, neutral= 3, some effect =2 and no effect =1)* of the KM tools in all three project phases *(i.e. pre, during and post construction)*. Table 3 presents the mean scores for each KM technology and technique. The most prominent IT tool is Microsoft Office (mostly MS Word, MS Excel and/or MS project) and face-to-face meetings are the preferred choice of the non-IT techniques. Although face-to-face meetings rank second for usage, it is considered most effective compared to emails, smartphones and laptops which are fall close behind. Interestingly, only 32% of respondents report their staff as having excellent computer skills compared to only 6% for external volunteers. HFH Canada uses an extranet called ShareNet to collect and share

information and facilitates monthly meetings inter-organisationally. However many HFH CONVOs express frustration with its interface which may explain the usage and effectiveness of databases in 6th place. In addition, while 61% of all staff has access to computers, daily usage pre, during and post project phases account for 68%, 61% and 61% respectively. Alarmingly, the use and effectiveness of LLPs are ranked 14th for respondents, but 42% said they participate in COPs which ranked 11th. Interestingly, 58%, 68% and 35% of HFH CONVOs said they always collaborate with 'for-profit' organisations pre, during and post project phases respectively, compared to only 19%, 10%, and 13% collaboration with fellow Canadian HFH CONVOs. Therefore, there are potential opportunities to improve Canadian HFH inter-organisational collaboration.

Table 3: Comparison of KM tools usage and effectiveness in Canadian HFH CONVOs

Canadian HFH CONVOs KMPs maturity

Maturity modelling is adopted to describe the development of any entity over time and can be used as a basis for comparison (Kuriakose *et al.* 2010). These models are necessary to assist organisations embarking on KM which require clear roadmaps or long-term visioning. Maturity models are characterised by various levels which certain key performance indicators must be fulfilled before progression to the next (higher) level is achieved. Kuriakose *et al.* (2010) conducted a morphological analysis of fifteen KM maturity models using dimensions and options comprising: context and applicability (i.e. general, organisational, industry, sector); stages (i.e. 4, 5, 6, 8); assessment (i.e. subjective, objective, unknown); validation methods (i.e. case study, empirical, unknown) and key areas (i.e. general or specific). The general knowledge management maturity model (GKMMM) was selected for this research due to its generic applicability at an organisational context, its 5 stages (i.e. initial, aware, defined, managed and optimised), and its empirical validation of specific KM areas (i.e. people, process and technology). However, a fourth KM area was added to the GKMMM to account for the environmental context which facilitates KM in HFH

CONVOs. The radar chart (figure 5) shows the overall KMP maturity where the highest average maturity level reached is level 3 (defined) by 66% of respondents. Figure 6 illustrates the maturity levels of the HFH CONVOs in each KM area. Knowledge process is the least mature area followed by environment, technology and people with standard deviations of 0.81, 0.75, 0.64 and 0.42 respectively.

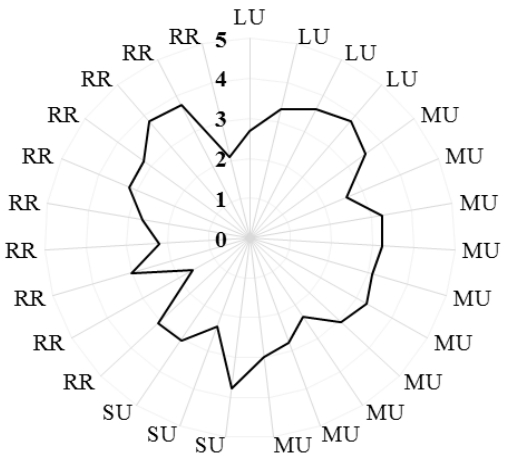

Figure 5: Knowledge Management Maturity of Respondents

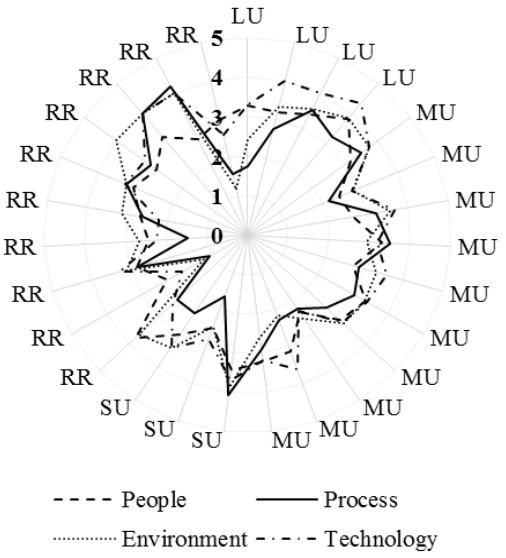

Figure 6: Knowledge Areas Maturity of Respondents

CONCLUSIONS

It is evident from the preliminary results of this *on-going* survey that the CSFs and KPIs Canadian HFH CONVOs perceive as important compared to what in actuality is critical, differ. Although the top five ranked KM tools are *Microsoft office, face-to-face meetings, emails, desktops* and *laptops*, the most effective tools were *face-to-face meetings, emails, telephones/smartphones, laptops* and *desktops*. There is certainly an opportunity to experiment with the use of Interactive communication technologies (ICTs) which can offer virtual face-to-face meetings supported with applications for real time exchange of information. Given the low response rate to date, the empirical results of KM tools usage and effectiveness motivates the researchers to apply supplementary qualitative study to identify barriers and opportunities for KM investment. The maturity analysis illustrates opportunities for improvement since level 3 *(defined)* is the highest level reached by 66% of respondents. This suggests that senior management provides a basic infrastructure for KM through strategies to formally facilitate knowledge processes by experimenting with pilot projects and providing incentives to manage knowledge. Despite this, CONVOs are challenged by limited temporary labour forces and budgets, and the learning curves of staff exposed to new technologies are also barriers to IT adoption. However, inter-organisational as well as 'for-profit' communities of practices collaborations' may offer an opportunity for Canadian HFH CONVOs to invest in KM tools which support improved organisational development.

FUTURE WORK

Subject to completion of the survey by September 2012, future work proceeds to the Action Planning phase of the AR cycle where HFH CONVOs will be contracted for collaboration with the researchers to brainstorm the adoption of KM tools. The objective is to compare the effectiveness of CONVOs who adopt both IT tools and non-IT techniques with ones who adopt only one kind of tool. A small number of HFH CONVOs who have not yet achieved a build may serve as prime candidates as a control group. The researchers intend on action planning by late 2012.

ON THE ROAD TO IMPROVED SCHEDULING – FITTING ACTIVITIES TO CAPACITY

Søren Lindhard[1] and Søren Wandahl[2]

[1] *Department of Mecanical and Manufacturing Engeneering, Aalborg University, Fibigerstræde 16, 9220 Aalborg, Denmark*

[2] *School of Engineering, Aarhus University, Dalgas Avenue 2, 8000 Aarhus, Denmark*

ABSTRACT

Last Planner System has through the sounding process increased the reliability of the schedule. The sound activities are moved to a buffer and afterwards selected to the Weekly Work Plans to match capacity. Therefore, in order to maximise productivity it is essential to ensure that the sounding process proceeds in a pace which ensures that enough activities are made ready to the Weekly Work Plans. Experiences from case studies are included. It is observed that site-mangers tend to either include at risk activities or to adjust the manning in order to mach work with capacity. Several different solutions to the problem are suggested and discussed. It is proposed to simplify the production by decreasing the number of trades and tasks completed at site. This can be achieved by increasing prefabrication, preassembly and modularization. If congestions in the making ready process occur buffers should be introduced to absorb the effect. This is achieved by introducing slack at the critical path and supplementing it with buffers of "time" flexible activities.

Keywords: Buffering, Flexibility, Last Planner System, Lean Construction, Scheduling.

INTRODUCTION

Improvement of production processes is often measured through productivity increase. Such statistical measures enable comparative analysis of different production conditions. Construction is often compared to traditional manufacturing, and several studies have provided statistical evidence for construction lacking behind the productivity development of traditional manufacturing (Bertelsen 2004; Winch 1998). This despite recently enhanced focus on improving the productivity of onsite production in construction. Efforts range widely, but this research follows the tail of Ballard (1999) who found that the amount of non-productive time in onsite production amounts to 50% of the total construction time. Thus Ballard's study only addressed non-productive time related to rework and delays. The indication is clear there is a large potential for productivity improvement in onsite construction.

[1] lindhard@m-tech.aau.dk
[2] swa@iha.dk

The Lean Construction philosophy originated in a quest to increase productivity in the construction industry (Liu *et al.* 2011). The first step into developing the lean tool Last Planner System (LPS) was taken when Howell and Ballard through a field study found that only half of the assignments in onsite construction were conducted as scheduled (Ballard 1999; Howell and Ballard 1995).

LPS consists of four main schedules (Cho and Ballard 2011; Salem *et al.* 2005). 1) The Master schedule which cover the entire construction process and establishes overview by including important milestones. 2) The Phase schedule which, between milestones, optimize the sequence of the different phases of the construction project. 3) The Look-ahead plan contains a making ready window from the Master schedule. In the Look-ahead window future activities are made ready for conduction. When ready, the activities are afterwards moved to a buffer of sound activities. Having a buffer of ready work improves the ability to respond to unforeseen events without affecting productivity (Ballard and Howell 1995; Koskela 1992). To ensure that ready work match capacity there should be at least a 14 day buffer of sound activities (Ballard 2000). 4) The Weekly Work plan is a one week plan of containing the activities which will be conducted. The plan is based on mutual commitments between the subcontractors. In the Weekly Work plan, activities are matched to capacity, and only sound activities from the buffer can be signed to the weekly Work plan (Ballard 2000). Securing that only sound activities end up in the Weekly Work plans increases the success rate of completed tasks and stabilizes the workflow (Ballard and Howell 1995). Finally, the quality of the schedule is measured through the PPC measurement. The PPC measurement serves as a feedback- and learning system. If low PPC is measured root causes are investigated and eliminated in order to increase productivity (Lindhard and Wandahl 2012b).

Making activities ready for conduction

Look-ahead planning is the backbone in LPS and it is the key element to ensure reliability in the schedule. Increased reliability is achieved through the making ready process where uncertainties in upcoming activities are sought reduced (Ballard 1999).

Activities are made ready by removing constraints. Traditionally the Lean Construction theory divides the constraints into seven main categories, known as ‘the seven preconditions of construction’. An activity can only be conducted if these seven preconditions are fulfilled (Koskela 1999). Hence, if one of the seven preconditions is not fulfilled the activity cannot be conducted and productivity will decrease. The seven categories of preconditions are:

1. Construction design; correct plans, drafts and specifications are present
2. Components and materials are present
3. Workers are present
4. Equipment and machinery are present
5. Sufficient space so that the task can be executed.
6. Connecting works, previous activities must be completed
7. External conditions must be in order.

Recently research has proposed to split “external conditions” into 3 categories (Lindhard and Wandahl 2012a). Currently the “external conditions” category covers several fundamentally different subcategories. Putting a name on the specific subcategories brings increased awareness and attention to the preconditions. This

helps the site-manager not to overlook any remaining constraints. The "external conditions" category was divided into the following:

7a. Climate conditions must be acceptable. The preconditions focus on external environmental effects such as rain, snow, wind, heat, cold etc.
7b. Safe working conditions must be present. The national "Health and Safety at Work Act" has to be obeyed to keep the employees safe.
7c. The surrounding conditions must be known. The precondition focus on securing that existing conditions, if necessary, are examined. Problems often arise during excavations or refurbishment assignments.

The making ready process is a continuous endeavour. To avoid congestions and to secure a constant flow there is a constant need for ready activities to feed the Weekly Work Plan. If the making ready process is progressing to slow in relation to the schedule the capacity will exceed the ready work resulting in delays and decreased productivity. Construction production is often organized in multiple trades with interacting and overlapping activities which have to be completed in the right sequence (Bertelsen 2003; Salem *et al.* 2006). Therefore, in order to provide the individual trade with sound work the scheduled activities needs to be ready. This makes the making ready process both complex and vulnerable. The complexity in fitting activities to capacity is examined through the following research question:

How can the complexity of the making ready process be decreased in order to fit activities to capacity to create a (continuous and) resistant workflow?

The research aim is to minimize and optimize the handling of misfits between the input from the making ready process and the capacity. The output will be a better workflow which results in increased productivity at site.

RESEARCH METHODOLOGY

Three construction cases were followed in order to observe the making ready process in onsite construction. Here, the focus was to observe arisen problems, their effect on production, and how they were handled.

Some selection criteria were applied in the selection of cases. Firstly, LPS should be used on the case. Phone conversations and mail correspondences with company consultants and site managers were used to ensure this. Secondly, it was a criterion that the contractor, as minimum, was a prime contractor with associating subcontractors. This secured a certain influence to and complexity of the making ready process. These selection criteria were added to increase the validity of the research.

The research was conducted as a qualitative research, where archives, observations, and unstructured interviews were used to collect data from the cases. By using a qualitative approach the making ready process is viewed in its context. The context is important because it affects the process and behavior at the construction site (Hartley 2004). This is supported by Yin (2003) who states that qualitative research is the only approach to answer how and why questions. Data collection from the three cases is listed in Table 1.

 ISBN: 978-1-84219-840-7 .

Table 1 Data collection at the three case-studies

	Case 1	**Case 2**	**Case 3**
Contract form	Turnkey contractor	Turnkey contractor	Prime contractor
Site observations	Once every forthnight in total 5 observations.	1-2 times every forthnight in total 8 observations.	1-3 times every forthnight in total 8 observations
Meetings partispated in	Subcontractor, foremen and safety meetings	Subcontractor and LPS meetings	Subcontractor, foremen, emergency and construction meetings
Observation length	10 weeks	10 weeks	10 weeks

EMPERICAL EVIDENCE

First of all it was observed that LPS was implemented differently in all three cases. This in terms of the theoretical correctness and completeness of the scheduling system. In all cases only part of the LPS system were applied. The main observations regarding the application of LPS are summarized in Table 2.

Tabel 2 Application of the making ready mechanisms in LPS.

	General observations
Look-ahead planning	Applied in all three construction cases, but in one case the making ready process had no attention. In one case constraints were dicussed in plenum. Finally, in one case soundness was tracked and constraints were removed using the 7 preconditions as a guideline.
Partisipation in the scheduling process	In two cases subcontractors and formens were directly included in the scheduling process, while in one case the schedule was conducted by management whereafter the subcontractors and formen could make comments.
Making activities ready	Responsibility was delegated to the responsible subcontractor.
The role of Site managment	Site management did not support or guide in the application of the making ready process. Furthermore, the progress and buffer status was not followed
Status of the making ready process	Random problems with the making ready process were observed. Here, scheduled activities could not be conducted because they were not, in time, made ready for conduction.
Responce to variation in the making ready process	A) Adding constraint activities to the Weekly Work Plan to match capacity. This was done with the hope that the constraints would be removed before the conduction started. B) Adjusting the manning of the individual subcontractor to fit capacity to ready work. Changing the manning is expensive it changes the sequence and slows down the production and is therefore a source to delay.

Delegating the making ready progress to the subcontractors entail that the efficiency of the process is left in the hands of the subcontractors. Since site management does not guide or support the subcontractors in the making ready process the likelihood for misusage is increased. If the making ready process is not applied correctly there is no guarantee that only sound activities end up in the Weekly Work plans. Thereby, unreliability has entered the schedule and productivity will decrease.

In all three construction cases congestions emerged between the making ready process and the Weekly Work Plans. The making ready process could not keep pace with the schedule and therefore could not feed the Weekly Work Plans. Even though the making ready process was applied differently there was no noticeable difference in the number of congestions. Moreover, because the making ready was not followed non-completions were difficult to predict and the effect was often unnecessary transmitted to interacting work activities.

Finally, the making ready process is tormented by changing soundness in the ready work activities, due to variation in the fulfilment of the preconditions. Hence it is important to notice that soundness is not a static condition. Varying soundness in ready work can occur in the workable backlog and in activities moved to the Weekly Work Plans. This introduces the risk that an activity in the Weekly Work Plans not is sound on the scheduled time for conduction.

DISCUSSION

From the three case studies it can be concluded that onsite production experience problems with feeding the Weekly Work Plans with ready work. The observations did reveal a tendency only to react after the problem occurs focusing on minimizing the effect. In order to improve the making ready process, root causes needs to be addressed in an attempt to prevent reoccurrences. In the following will different approaches to improve the making ready process will be discussed.

One approach to avoid congestions in the making ready process would be by reducing the number of task conducted at site. Prefabrication, preassembly and modularization are all concepts with that in mind. Simplifying the process is another method to reduce waste (Hopp *et al.* 1990; Koskela 1992). According to Koskela (1992) *"the very complexity of a product or process increases the costs beyond the sum of the costs of individual parts or steps."* By reducing the number of tasks and keeping the production simple the interactions and interdependencies between the subcontractors are decreased. This provides overview and increases the transparency of the process and makes the project easier to schedule.

Simplification can also be achieved by reducing the number of trades working at site. Again the number of interactions and interdependencies between the subcontractors will be reduced. Reducing the number of trades could be achieved by increased prefabrication, preassembly and modularization. Since it is the subcontractors' responsibility to make work ready, the process will now be affected by fewer variables and dependencies reducing the risk and effect of non-ready activities. Ideologically modularization will simplify the assembly process at site leading to less specialized craftsmen. Less specialization equals more flexibility and adaptability in the assembly process. Moreover, less specialization could reduce the number of trades resulting in more work to the remaining subcontractors. The subcontractors are able to faster react on changes and make adjustments, to fit the ready work activities, without just changing the manning. If to specialized the subcontractors are depending on the soundness of a specific activity. Thus with more work on site not ready activities can more easily be replaced by ready work from buffers.

Another approach to avoid congestions in the making ready process is by increasing flexibility of the tasks in the schedule. An increased flexibility loosens the linkages and interdependencies between the subcontractors. Moreover it gives an increased

 ISBN: 978-1-84219-840-7 .

productivity, reliability, and it improves the ability to respond on unforeseen events (Ballard and Howell 1995; Koskela 1992).

In general activities in the sequence can be divided into flexible and inflexible work tasks. The free and flexible activities can be used as buffer activities to handle variation without affecting the production. While constraints from the physical relationship between construction components, trade interactions, path interference, and code regulations hinder movement in the inflexible task and tie them to the sequence (Echeverry *et al.* 1991). But even on the critical path slack between activities can be used to absorb small variations. If these variations is not absorbed the productivity will decrease (Tommelein *et al.* 1999).

Another way to increase the flexibility of the production is to increase the flexibility of the workforce. This could be by using multi-skilled crews to make the crews cover a larger variety of work tasks. This way interactions and interdependencies, between crews, could be removed. Furthermore, overtime could be used as a last resort to absorb unexpected delays in activities on the critical path.

Finally, flexibility can be achieved by applying buffers. Since traditional buffering is expensive it is important not to over-buffer but to keep the buffer size adequate and fitting to current uncertainty. If enough work not is made ready the buffered activities will fill up the empty space and keep the production running. This way buffering absorbs variation in the production as well as in the making ready process and increases the robustness of the schedule. If uncertainty and variability is decreased so is the need of buffering. Thus a simplified and more flexible production will reduce the need of buffering.

In addition to traditional buffers where the backlog consists of the following work activities the backlog should be supplemented with flexible activities. These activities can be conducted without regarding the sequencing. Therefore, they have no bindings and can be “stored” until needed. Since preconditions can vary it is important to check-up on the soundness of buffered activities. A weekly “health check” of all activities could be implemented in order to prevent not-sound activities to emerge in the buffer as well as in the Weekly Work Plans.

The ability to convert the production from one task to another is called adaptability. When applying buffers it is important that the switch from the scheduled to the buffered activity is as fast and smooth as possible. By minimizing the time to adapt waste surfacing as non-productive time is removed. In a changing environment such as onsite production where changes is an everyday experience the ability to adapt is crucial. An increased adaptability improves the ability to respond on unforeseen events. This way adaptability is strongly connected to flexibility.

The key rule when avoiding congestions in the making ready process is that activities should always be fit to capacity and not capacity to activities. Therefore, lowing the manning will slow down the production and should therefore only be used as a resort if capacity decreases. To achieve the synergy all the proposed approaches should be used in a combination and fit to the individual construction project.

CONCLUSION

Today changing manning seems to be the solution to handle congestions in the making ready process. Varying the manning is not ideal since it slowdowns the production which result in delays. Ideally problems should be caught at the root. Therefore, in order to avoid congestions in the making ready process it is recommended to focus on simplifying the production by minimizing both tasks and trades at the construction site. Keeping the production simple reduces the number of interactions and interdependencies between the different subcontractors which makes the construction project easier to schedule.

In spite of all precaution error will occur. Therefore, in order to minimize the effect on productivity of such occurrences actions must be taken. Two different approaches are suggested to absorb the variation: increased flexibility and buffering. An increased flexibility loosens the linkages and interdependencies between the subcontractors and improves the ability to respond on unforeseen events. It is suggested to increase flexibility by introducing slack between activities on the critical path. Slack is used to absorb critical variations in productivity.

Moreover it is suggested to use buffers to achieve flexibility in the production. Here traditional inflexible buffer activities in the workable backlog should be supplemented with flexible buffer activities. Flexible buffer activities are activities which not are tied to the schedule. Finally, it is stated that in order to minimize waste more focus is needed on the adaptability to makes this process as efficient and smooth as possible.

PROJECT MANAGEMENT SERVICE CHALLENGES

Benita Zulch[1]

[1]*Department of Quantity surveying and Construction management, University of the Free State, Bloemfontein, South Africa*

ABSTRACT

The research endeavors to prove that quality services in the construction industry, as opposed to physical products, pose some unique challenges. Services have unique characteristics, such as intangibility, perishability, simultaneity and variability, and these require a specialized approach. The contractor, as service provider, should develop a mind shift not only from profit orientation, but also service orientation. The service provider should place more emphasis on those elements that contribute to the successful completion of a service. The method of research included sending a questionnaire to a group of construction managers and project managers to determine opinions on a quality service and whether services were at an acceptable level of quality. The results showed that the fluctuations in quality of services delivered, difficulty in assessing quality, absence of advice and comparing services and service providers were mentioned as issues between parties involved in a quality-service construction project. These issues can improve service delivery between service providers/contractors and clients. The practical implication is that construction managers should place more emphasis on the quality of strategic elements, such as total customer satisfaction and a high quality-service standard in order to ensure the successful completion of projects in a competitive market environment.

Keywords: construction management, project management, quality, services, strategies.

INTRODUCTION

The purpose of this paper is to illustrate that a project manager has to apply a quality-services approach and need to be more service orientated in order to be able to complete a project successfully within the time and budget available for the project. Profitability as the main aim to ensure a satisfied client is a short-term approach. To ensure long-term profitability, project managers and other professionals should be pro-actively service orientated. This can be achieved by creating long-term relationships, by ensuring expert inputs and dynamic service to clients through communication. Contractor/client satisfaction may result from building good relationships. PMBOK (2008) states quality as the degree to which a set of inherent characteristics fulfills requirements. This implies that the service provided must be of such a standard or quality that it fulfills the client's needs. According to Kotler and Amstrong (1997), a service is an intangible activity or benefit offered by one party to another. Thus, quality service is an intangible activity or a specific standard that fulfills a client's needs and expectations. Managing quality services, project managers need to use strategies to make it possible to complete the project successfully.

[1] zulchbg@ufs.ac.za

CHARACTERISTICS OF SERVICES

Clients are the reason that the building industry exists. The industry is a service provider. The following are unique characteristics of services implying problems not experienced by physical products. The characteristics are as follows:

Intangible services cannot be seen, tasted, felt, heard or smelled. To reduce uncertainty, a buyer looks for signals of service quality and draws conclusions on the quality of the equipment and communication that they have experienced. Moeller (2010) states that a service is a deed, performance or effort. A project manager therefore has to make the service tangible in one way or another (Kotler and Armstrong 1997; Du Plessis and Rousseau 2003). The project manager will order material and equipment for the project without seeing it and believe the supplier that it will be of a standard that is acceptable for the project.

Perishability indicates that services cannot be stored for later use (Kotler and Armstrong 1997; Du Plessis and Rousseau 2003). Perishability is not a problem when demand is steady, but when demand increases, construction companies need more equipment to handle the demand and try to satisfy clients. Construction companies should design strategies to handle economic fluctuations.

Simultaneity or inseparability indicates that a service cannot be separated from the providers, whether the providers are people or machines. This implies that the services are produced and consumed at the same time (Kotler and Armstrong 1997; Du Plessis and Rousseau 2003). Service providers are often physically present when consumption takes place, while services are first sold, then produced and consumed (Moeller 2010). During the execution phase of the project, the project manager will work with contactors who provide the necessary services without which the project cannot be undertaken. Therefore, the project manager needs so understand how to handle different situations.

Variability or heterogeneity implies that the quality of the service depends on who provides it, as well as when, where and how it is provided (Kotler and Armstrong 1997; Du Plessis and Rousseau 2003). A client will decide on a project manager who consistently provides the best service with every project. The project will depend on a group of stakeholders who all deliver a service and it is the responsibility of the project manager to select a group of people who have the skills, knowledge and personality whom he can rely on to deliver those necessary services when, where and at the standard stipulated by the contract.

The project manager needs to understand the *characteristics* of a service to make it possible to manage a project successfully and of the standard expected by the customer. A client has to be satisfied in three areas, namely the building, the organization or service and the people. Clients are groups of individual people with needs to be satisfied and emotions to be expressed. Buildings are the normal achievement of the industry. Organisations require buildings or services and have an organizational means of financing these requirements (Boyd and Chinyio 2006).

The project manager undertakes the responsibility of understanding the clients and their needs, and how to satisfy these needs, and what influences their decisions, and how they make decisions.

Furthermore, it is important that the project manager knows the difference between the needs and wants of clients. Wants are things that clients can live without, but would like to have. Needs, according to Maslow (in Strydom, Jooste and Cant 2000), seem to be fairly universal for each individual and is something clients cannot live without. Contractors must therefore know what is essential and what the clients' desires are.

SERVICE-ORIENTATED VS A PROFIT-ORIENTATED APPROACH

Meeting customers' needs and wants economically is vital to the survival of any organization or project. This traditional profit-orientated approach has changed over the last few years to a service-orientated approach (Steyn 2003). The primary focus of quality management is total satisfaction of customers within a management environment that seeks continuous improvement of all systems and processes (Pun and Nurse 2010). However, the relationship between clients and the industry is not one of mutual enjoyment. In many cases there is a mutual dislike and distrust. Clients see the industry as a problem and often express this feeling in public. The industry sees the clients as a problem and although the industry may to work for clients, behind closed doors they complain about the clients. Clients need better value from their project and construction companies need reasonable profits in order to assure their long-term future (Boyd and Chinyoi 2006). This implies that construction companies need to shift their focus towards the clients. A customer-orientated approach will ensure their future.

Berry (in Du Plessis and Rousseau 2003) suggests the following quality-service methods for cementing a long-term relationship between contractors and customers/clients:

The design of a core service. A core service typically attempts to satisfy central rather than peripheral market needs and provides the basis on which customer relationships can be established.

Customizing the relationship. Tailor services to meet the specific needs of individual customers. By doing so, there will be no incentive for a customer to start afresh with a new service provider.

Service augmentation. Service augmentation refers to efforts to differentiate the service offering by providing additional benefits, valued by customers and not offered by competitors.. The objective is to encourage customer loyalty.

Relationship pricing. Relationship pricing also attempts, by fostering customer loyalty through incentives, to encourage customers to make use of the full range of services offered by the project manager.

The above quality-service methods help to create loyalty and may be used as elements of strategy to build long-term relationships between the contractor and the client (Congram, in Du Plessis and Rousseau 2003). A relationship is initiated and developed through communication (Boyd and Chinyio 2006).

To become more service orientated, contractors need to understand how clients make decisions. It is suggested that clients make decisions according to their beliefs, norms and values that were formed by influences. These influences are based on their individuality and the environment they grew up and find themselves in.

The influences of a clients' individuality are (Du Plessis and Rousseau 2003):

Needs. Such as physical or emotional requirements.

Motives. Inner states that activates, motivate and direct behavior towards goals. Motives make a person aware of their needs and give them a reason for acting on these needs.

Personality. The combination of unique individual characteristics, which reflects consistent and enduring patterns of behavior. Personality makes an individual act in a specific manner in a specific situation.

Perception. A process by which people select, organize and interpret sensory stimuli into a meaningful and coherent picture.

Learning. Learning reflects changes in the probability of behavior as a result of previous experiences.

Attitudes. This refers enduring systems of positive or negative evaluations, feelings and actions.

The environmental influences that have an impact on clients' service choice may be (Du Plessis and Rousseau 2003):

Cultural influences. These refer to beliefs, norms, values and customs that are learned from the society and lead to common patterns of behavior.

Social influences. These influences refer to communication.

Reference group. A group with whom one identifies in such a way that one tends to use the group as a standard for self-evaluation and as a source of values and goals.

Family influences. These are influences of family members who may in some instances assist with decision-making choices.

Economic demand. These influences refer to potential purchasing power, based on the availability of money, or due to the lack of money or creditworthiness. Price, financial risk and investment opportunities are closely associated with income.

Business and marketing influences. These influences refer to direct contact with clients. These influences can also stem from good or bad experiences in the past.

The influences illustrates that every client should be seen as an individual, knowledge of an individual is important and the understanding of the environment where these individuals live may be a viable approach. Communication can be used in the process to convince clients to make use of a specific quality service.

QUALITY

Quality management refers to the activities that determine quality policies, objectives, and responsibilities. The processes of a quality management system include quality planning, quality assurance and quality control (PMBOK 2008). According to Knipe (2002), quality relates to the characteristics by which an output is assessed by clients or stakeholders. A quality plan describes in detail the quality standards for the project and the quality criteria that are used to determine whether the project is correct (Heldman 2011). Clients evaluate quality on the fact that a service meets their needs at the right time at the right price. The process of quality or the quality management plan is as follows:

Quality planning

Quality planning is the process of identifying the quality of standards to be achieved and the test required to confirm the service of a project is on standard. Quality is planned and built into the project from the conceptual stage and is part of the contract agreement. The quality policy indicates the quality of services that should be rendered and the procedures state how to achieving the quality of services delivery (Steyn 2012; Burke 2010). Project managers need to discuss the level of quality with stakeholders early to ensure that everyone maintains that level of quality for the duration of the project. If the quality level is changed or dropped, the project manager must implement the quality-control and quality-standard process to regain the quality level (Dow and Taylor 2008).

Quality assurance

Quality assurance of services is the process of defining, planning, implementing and reviewing the management process in order to predict with confidence that the required quality of service that will be delivered consistently (Burke 2010). This implies confidence that all the necessary plans, activities and effort will be undertaken to deliver the correct quality of service in order to achieve the successful completion of a project. Quality-assurance activities focus on the process for managing and delivering solutions. The project manager, team members and other stakeholders perform various quality-assurance processes throughout the project (Dow and Taylor 2008). Steyn (2012) states that the quality policy, audits, planning, procedures and work instructions,

and the selection and training of staff are some of the more commonly used tools in the quality-assurance field.

Quality control

Quality control is the process companies go through to confirm that the service has reached the required quality as determined by the specifications in the contract. The quality-control system also defines the methods of inspection and testing (Burke 2010). Steyn (2012) states that the more commonly used quality-control tools are inspection, testing, statistical methods and pareto diagrams which help the project manager to deliver a successful project.

QUALITY STANDARDS

The quality policy contains guidelines rules or characteristics that should be followed regarding quality standards for projects and the policy, (Heldman 2011). The quality standards certify processes and systems of a project, not the service itself. The ISO 9000-1987 is a series of quality standards based on categories, design, production and service delivery (Dow and Taylor 2008). Project managers must try to achieve the ISO 9000 quality standards on projects to improve the service they provide to the customer.

Project managers must determine where in the project quality testing should occur and how the team can improve the quality of the project. The project manager will then determine the focus area for quality testing. The quality management plan implies total satisfaction of the customer at the lowest cost. The success of total quality management mainly depends on the commitment of top management and their willingness to change the quality culture. Construction companies implement total quality management for improving customer satisfaction, obtaining a better quality of products and a higher market share (Isik, Arditi, Dikmen and Birgonul 2009).

MANAGING QUALITY-SERVICE STRATEGIES

Successful service depends on the management of strategies to achieve quality services. Strategies that companies can apply are differentiation and service profit. Service profit means the construction company is paying attention to both the customers and the employees. International service profit can be achieved by the training and motivation of the customer contact employees, external and traditional use of the 4Ps and interactive marketing, which means that service quality, depends on the quality of the interaction between the parties (Kotler and Armstrong 1997). Differentiation means customers want something different from the service than from that of the competitors, and it can be achieved by the design of a superior delivery process that contributes to performance improvement (Walker 2007). Bolton, Grewal and Levy (2007) state that strategies for competing through services are shareholder wealth with profits that flow to the company, managing customers' perceptions of service, customized pricing for quality services, service excellence in the implementation of services, and planning for service recovery by reducing variability in service quality.

Add-ons to these strategies can be commitment and the leadership (Best, Langston and De Valence 2003) of top management to quality services, high-quality standards and communication about concerns and providing feedback (Kotler and Armstrong 1997). Benchmarking may also be used as a strategic tool.

THE RESEARCH METHOD

A questionnaire designed by the University of the Free State consisting of two sections was distributed to thirty-two respondents. Section One consisted of project risk management-related questions and Section Two consisted of project quality management. For the purpose of this article, respondents were requested to indicate their opinions on the questions in Section Two which were analyzed. The response rate

was 100%. The profile of the response rate indicates a reasonable balance between professionals who responded to the questionnaire; architects (9,3%), quantity surveyors (12,5%), engineers (15,6%), construction managers (9,3%), project managers (22,1%) and (37,5%) indicate that they act as project managers and one of the other professions.

FINDINGS

The respondents indicated that a comparison of quality standards with those of the competitors' quality standards is important (81%), whilst benchmarking (41%) is the instrument that most companies use for comparisons. Project managers must make use of the ISO 9000 as a benchmark in comparing themselves with their competitors. Respondents indicated that a comparison between quality standards and the service itself is essential, for service providers, but it does not happen in reality. The respondents' results regarding their company's customer orientation were compared with the literature. Respondents rate customer orientation (87%) considerably higher than profit orientation (13%).

Respondents indicated that for projects they were involved in, they have a quality process in place for planning, audit and control. Quality training was rated fairly important and quality communication and communication about quality equally important. Fluctuations are experienced in the quality of service delivered, although it was difficult to assess quality.

Understanding quality and how the steps to quality may improve the communication network and process, and by doing so, improve communication itself. It is important to apply the steps to quality and value when drawing up a project's planning documentation and during construction.

CONCLUSIONS

The study clearly shows the importance of quality services in the construction industry. Currently a mind shift from profit orientation to service orientation has taking place in the construction industry. Needs are satisfied when a client is fully satisfied with a service and when there is a guarantee that the product or service is of such a quality that it delivers value for money.

The elements that contribute to the successful completion of projects are quality planning, quality assurance, quality control and communication about quality. Communication instruments related to the construction industry and the role construction professionals may play in improving the effectiveness of correct procedures and systems.

An effective tool to build a quality relationship with a client is communication, a strong link between the project manager, the client or professionals, and the construction project. Figure 1 shows the quality communication triangle.

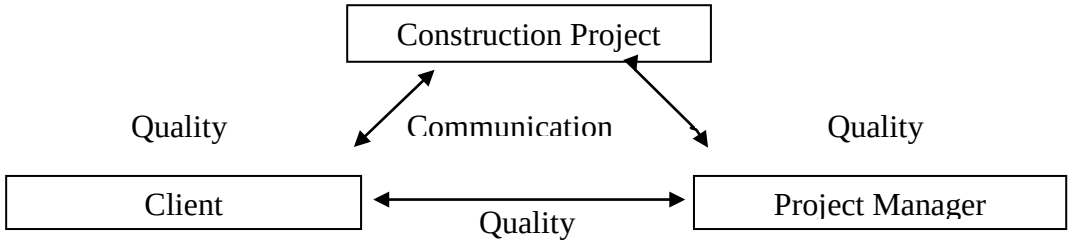

Figure 1: Quality communication triangle

Communication is the element which sells and resells ideas, explains the scope and methodologies of the project, bargains with providers and suppliers, or negotiates to settle disputes or conflict and build a relationship (Steyn 2003).

Clients and contractors should communicate effectively from the planning stage. They should also discuss all the concerns and issues of importance to the project to ensure a sound relationship that will focus on a long-term relationship. Communication, on a

more regular basis, will improve the quality of services and build relationships during the entire life of the project.

[2] *Head of Department, Quantity Surveying and Construction Management, University of the Free State, PO Box 399, Bloemfontein, South Africa.*

ABSTRACT

Some project managers within the South African construction industry seem to have a lack of sufficient and effective management skills. This study aims to suggest solutions and to propose a model with guidelines for creating a profile for effective construction project management, as well as to determine the characteristics and skills needed by such a professional. Basic management principles, tasks, responsibilities and the behavior of the project manager are studied and the results may form the basis for creating a probable profile for a construction project manager. The methodology used was to do a comprehensive literature study, followed by a structured questionnaire sent to professions involved with a construction project manager such as architects, quantity surveyors, engineers, etc. The findings showed that the areas of management and the functions and responsibilities of the project manager can be regarded as the task of the project manager, while certain skills and characteristics can assist the project manager to perform the necessary management tasks successfully. The profile for a construction project manager is proposed by identifying the task and the resources needed for the successful execution of the task. The practical implication is that project managers in the construction industry should identify and develop the necessary skills to comply with the suggested profile.

Keywords: Built environment, construction project management, competencies, maturity, profile requirements.

INTRODUCTION

Project managers within the construction industry possibly have a lack of sufficient and effective management skills. This study aims to find solutions, and to propose a model with guidelines for creating a profile for effective project management, as well as to determine the characteristics and skills needed by a project manager. Basic management principles, tasks, responsibilities and the behavior of the project manager are researched and these results may form the basis for creating a probable profile for a construction project manager.

[1] archerm@ufs.ac.za
[2] versterjjp@ufs.ac.za

If a profile can be created based on the research, this profile might be used to prepare the project manager for effective management and the successful completion of projects. Construction project managers can be measured by means of this profile and adapted where necessary to meet the requirements. Gaps that are thus identified can be rectified. This profile can form the basis of model proposing to measure the maturity of the profile for construction project managers in construction project management companies. Individuals will also be able to evaluate themselves and to make adjustments, where necessary.

The research shows regular cooperation between project managers in the construction industry and other stakeholders, as well as that poor management by the project manager contributes to project failure. Although management guidelines exist, it is evident that project managers do not implement them effectively. This might have a negative impact on projects. It is important that the project manager has some characteristics and skills to implement management functions successfully. When a construction project is undertaken, the timely identification of tasks, activities, areas of management, functions and responsibilities is important in order for the project manager to be knowledgeable about what is expected.

The areas of management, as well as the functions and responsibilities of the project manager can be regarded as the task of the project manager, while certain skills and characteristics can assist the project manager to perform the necessary management tasks successfully. The profile for a project manager is compiled by identifying the tasks (areas of management, functions and responsibilities) and the resources (skills and characteristics) needed for the successful execution of the task.

Project Management Areas

The areas of management of construction project management might be regarded as an important management guideline for the construction project manager and might therefore contribute to the identification and development of a profile for a construction project manager.

According to the PMBOK (2008), there are nine areas of management, which include: integration management, scope, time, cost, quality, human resource, communication, risk and procurement management. Zack (2004) adds another four areas of management specific to the construction industry, namely claims, financial, environmental, and health and safety management.

Each of these areas of management must be managed successfully by the construction project manager to ensure project success. These specific areas might be regarded as a very important management guideline. It might also be an indication of all the necessary knowledge, management skills and characteristics of the project manager. Skills such as leadership, communication and organizing, together with people skills, might contribute to the successful management of these areas.

Project Management Functions

The contribution of management functions by the construction project manager might be significant for the profile development, because of the relation between management functions and the necessary skills and characteristics of the construction project manager. To perform the management functions effectively and efficiently, the construction project manager must display certain management skills and characteristics. These must be developed and applied effectively. These construction

project management functions might be a clear indication of required characteristics and skills, as will the construction project management areas, functions and responsibilities be an indication of the important and necessary skills and characteristics.

For the purpose of this study the focus will be on the following management functions: planning, organizing, leading, coordinating, human resources, communication, control and decision making.

Responsibilities of the Project Manager

According to Heerkens (2002), the responsibilities of the construction project manager can be divided into four categories. The focus of each responsibility is different, which contributes to the diverse role of the construction project manager. The categories include: responsibilities towards the project, the project team, the organization and the construction project manager.

When these responsibilities are met, it should have a significant impact on project success. The responsibilities of the construction project manager contribute to the development of the profile because, together with the construction project management areas and functions, certain skills and characteristics can be identified, which then lead to the establishment of profile requirements for the construction project manager.

Characteristics such as leadership, people skills and technical skills support the execution of the responsibilities of the manager. It is very important that the project manager realizes and accepts responsibility for the project, the team, his organization and himself. Professional conduct and ethics are also very important.

Skills of the Construction Project Manager

Skills can be identified as the ability to translate knowledge into action that results in desired performance (Schermerhorn 2010). According to Best (2010), the competence and efficiency of the project manager should result in improved project results and limit project costs. Fox and Van der Waldt (2007) argue that the lack of skills on the part of the project manager, the project team and the contractors and/or stakeholders contributes to project failure.

Essential skills include: leadership skills, communication skills, and planning, negotiating, motivating and people skills. It is sometimes necessary that the project manager has a flexible personality in order to adapt to the ever-changing environment. It is also advised that the project manager continuously improves his abilities and skills (Andersen et al. 2004).

Ingason and Jonasson (2009) refer to the International Project Management Association's *The eye of competence*. This model illustrates three areas of competence of the project manager. It includes behavioral competencies, contextual competencies and technical competencies.

When certain management tasks and activities are identified, it is important for the construction project manager to have the necessary skills to execute and manage these tasks and activities successfully. Project management skills and functions go hand in hand, because a management functions cannot successfully be carried out without the necessary skills.

Characteristics of the Construction Project Manager

The investigation of certain characteristics of the project manager is needed for the development of a manager's profile. It will contribute to the identification of the necessary skills and characteristics to apply in certain management areas, functions and responsibilities. Certain characteristics are important to have; it will contribute to overall project success.

Burke and Barron (2007) imply that ethics, integrity and professional conduct are very important for the project manager.

Skills, together with characteristics, are needed to execute and manage areas, functions and responsibilities effectively and efficiently. Project success is dependent on the project manager's skills, characteristics and abilities.

RESEARCH METHODOLOGY

Both qualitative and quantitative research methods were used during this study. It includes a comprehensive literature study, followed by an investigation by means of a structured questionnaire to test the hypothesis. The questionnaire was constructed on the basis of the literature study. The literature review included various aspects of construction project management, but the focus of the research was to determine the profile requirements for the project manager to execute the task of management successfully. To determine these profile requirements the project management areas, project management functions and responsibilities of the project manager were investigated which then lead to the investigation of the contribution of the characteristics and skills of the construction project manager towards this profile.

Questionnaire Construction

The purpose of the questions included in the questionnaire is the following: to group the respondents in the following groups: clients, consultants, contractors and other relevant professions; to determine the qualifications of these respondents; to determine the frequency that these respondents are in a close working relationship with a construction project manager; and to determine the importance and successful application of certain skills.

The validity and reliability of answers are confirmed by the qualification and experience of the respondents. Consultants include architects, engineers and quantity surveyors. Contractors and subcontractors as well as clients who are involved in the construction industry contributed to the survey. Other relevant professions, which also form part of the respondent profile, include property developers, facility managers and academics in the built environment.

Sample

Fifty-five (55) questionnaires were distributed among consultants, contractors, clients and other relevant professions in the construction industry in South Africa. A success rate of 71% was achieved.

Data Analysis

The data were summarized descriptively, using Microsoft® Office Excel® 2007 to generate spreadsheets, tables and figures.

RESEARCH RESULTS AND DISCUSSION

Personal Data and Profile

Respondents include clients (5%), consultants (46%), contractors (21%), other relevant professions within the built environment (23%) and unanswered questions (5%). Eighty-seven percent (87%) of the respondents have a degree that is relevant to the built environment. Five percent (5%) have a diploma, five percent (5%) have alternative, yet relevant qualifications and three percent (3%) of the respondents have matric. Sixty-five percent (65%) of these respondents indicated that they were often or always involved in a close working relationship with a construction project manager on their projects. This is an indication of the necessity of the construction project management profession in the built environment.

Effectiveness of Management

The respondents (66%) indicated that they experience a lack of effective management by the project manager on a regular basis. The fact that the lack of effective management is experienced creates a problem regarding the successful management and completion of projects. This lack of effective management by the project manger might have different causes. Therefore it is important for the project manager to develop and apply the necessary skills and traits to ensure that it is not the cause of nor contribute to project failure. The respondents (84%) also indicated that the lack of effective management had a significant impact on project success. The impact on the project might have significant consequences, such as additional time and cost of the project, quality, and scope could also be affected by the lack of effective management.

Effectiveness of Applied Management Guidelines

The respondents were asked to indicate whether they experienced that construction project management guidelines were not effectively followed and applied by the manager. These guidelines include PMBOK (2000, 2008) and Construction Extension to the PMBOK (2007). These guidelines empower the manager to execute his tasks and activities more successfully. The respondents (72%) indicated that they experienced a lack of project management guidelines being applied by the manager on a regular basis. However, this is very alarming, due to the fact that project success is at stake.

Eighty-seven percent (87%) of the respondents also indicated that the lack of applied management guidelines had a huge negative impact on project success.

Project Management Elements: Importance versus Application

Various important construction project management elements were identified based on the literature study. The respondents were asked to indicate the importance of each, as well as the successful application of each of these important elements.

Through the identification of the various important management elements the profile requirements can be established. Elements such as organizing, planning, leading, coordinating, human resources, communication, control and decision making were identified as the most important management elements. These elements are derived from the thirteen construction project management areas, the project management functions and the responsibilities of the construction project manager. Skills and traits of the manager also contributed to the identification of these elements. The literature study was the basis for this identification.

 ISBN: 978-1-84219-840-7 .

From Table 1 it is clear that there are discrepancies between the importance and the successful application of these management elements. It is also clear that some of these management elements are not applied successfully or effectively. This might contribute to project failure. Skills and traits support the execution of these tasks and activities. The current application of construction project management elements is disappointing and clearly indicates areas of development.

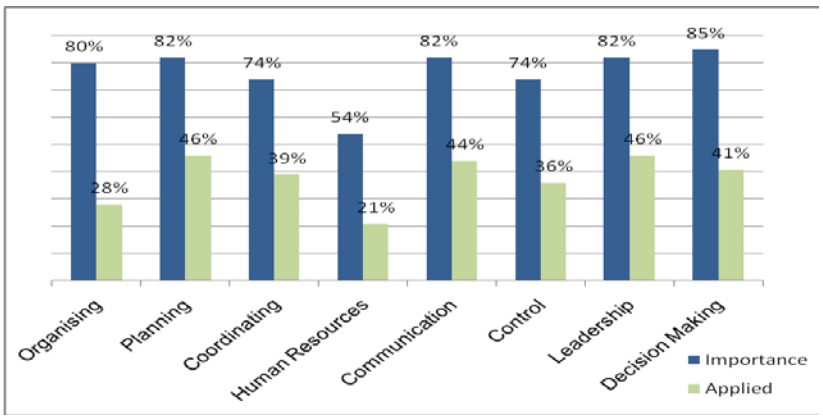

Figure 1: Importance and application of important management elements.

In Figure 1 it is clear that there is no definite correlation between the importance and the successful application of management elements by the project manager. The main focus of this paper is not to compare the importance to the application, but to establish certain development areas. A maturity model can be used to illustrate these areas of development of the identified construction project management elements as mentioned above.

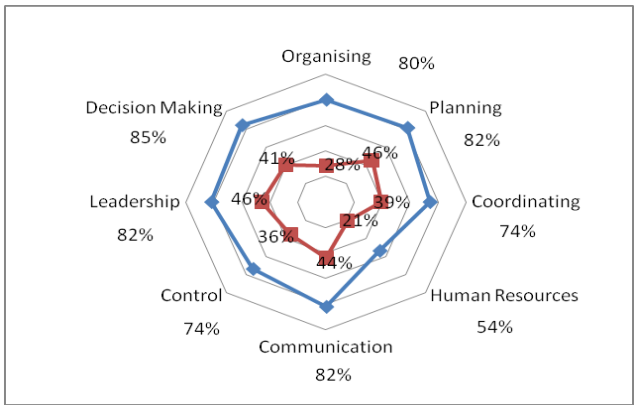

Figure 2: Profile model: Importance and current status

The eight fundamental construction project management elements, now known as profile requirements, are indicated in this maturity model. The importance of each, as well as the current status, is illustrated in this model; thus the areas of development are also clearly identifiable. By using this maturity model construction project, management companies and individuals can measure themselves against this model and make the necessary changes.

CONCLUSION AND RECOMMENDATION

In this study the thirteen areas of construction project management areas, various management functions and key responsibilities of the manager were investigated. These three aspects can be seen as the management task of the construction project manager. To execute this management task the manager needs certain skills and personality traits. This can be regarded as the resources. The investigation of these important construction project management aspects contributed to the identification of fundamental elements of management known as profile requirements.

Based on the data collected, a maturity model was established in terms of profile requirements. This proposed model can be used by construction companies and individuals to measure and determine certain areas of development (relation between importance and application) and make the necessary changes.

THE EFFECTIVENESS OF CONSTRUCTION CONTINGENCY IN CONTRACT DELIVERY IN NIGERIA

Wasiu Adeniran Bello[1] and Koleola Tunwase Odusami[2]

[1]*Department of Building, University of Lagos, Akoka, Yaba, Lagos, Nigeria*

[2]*Department of Building, University of Lagos, Akoka, Yaba, Lagos, Nigeria*

ABSTRACT

Cost and time overruns are attributable to unforeseen events for which risks and uncertainties were not appropriately estimated by adding an arbitrary percentage allowance for changes that experience shows will likely be required. Contingency is a predetermined amount or percentage of the contract held for unpredictable changes and used to cater for events that are unforeseen which threaten the achievement of objective within the defined project scope. The study determines the percentage contingency on the estimated cost of construction and compares contingency sum with the cost of total approved variation (and fluctuation). In order to achieve these objectives, the research sample selected for this study is quantity surveyors in client and consulting organisations. Data of past projects were received from 21 organisations which include information of 99 projects of varying sizes and contract types. Descriptive statistics was used to describe the characteristics of the sample. Standard deviation, coefficient of variation and analysis of variance (ANOVA) were used for exploring relationships among variables and compare groups. The study revealed that construction contingency averaged 5.53% of the estimated contract sum while variation averaged 11.62%, which means that contingency sum is less than the total approved variation by an average of 6.09%.

Keywords: budget, contingency, percentage, quantity surveyor, variation.

INTRODUCTION

In a construction project and from the client's point of view, contingency is the amount that is set aside to cope with uncertainties during construction. Contracts provide for contingencies to pay for unknown conditions such as price escalation of a product; design changes in scope or due to errors and omissions; or necessary construction changes that are realized on site during construction (Hart, 2007). Touran (2003) posited that it is common to assign contingency value to both cost and schedule because project uncertainties can affect project schedule as well as cost. The ambition of building clients and consultants is to keep the final construction cost within the initial budget estimate that includes a justified additional amount that caters for contingency. In construction and engineering projects plans and cost estimates are

[1] wasbel2001l@yahoo.co.uk
[2] ktodusami@yahoo.com

usually drawn to ensure that the work is carried out to the desired quality, within allowed time, and within budget. According to Baccarini (2004) Contingencies are often calculated as an across-the-board percentage addition on the base estimate, typically derived from intuition, past experience and historical data. Many authors have described this approach as arbitrary and or unscientific including Thompson and Perry (1992), Hartman (2000), Baccarini (2004), Kerlsen and Lereim (2005), (Bello and Odusami, 2008, 2009). Despite the efforts of researchers in developing scientific and statistical methods of estimating and management of contingency, cost experts and practitioners in the construction industry are still glued to the conventional method of lump sum or percentage addition (Bello and Odusami, 2008). Therefore, this study assessed the effectiveness of construction contingency by examining the percentage contingency allowed on the estimate and its comparison with the percentage variation on contract delivery in Nigeria. The findings of this study shall assist the construction practitioners to establish an effective contingency allowance that is applicable in the industry.

Research hypothesis
H1: Contingency sum is less than total approved variation and fluctuation

PREVIOUS WORKS

The major cause of disruption, delay and dispute on construction contracts are changes and risks which are inevitable in construction. According to Risner (2010) no matter how hard architects and engineers try to develop a set of construction drawings that are infallible there are almost always errors or omissions embedded in their drawings. Ashworth (1999) posited that risk can be mathematically predicted, whereas uncertainty cannot. Nworuh and Nwachukwu (2004) asserted that experience on many projects indicate poor performance in terms of achieving time and cost targets hence, many cost and time overruns are attributable to either unforeseen events for which uncertainties were not appropriately estimated. An amount of money used to provide for uncertainties associated with a construction project is referred to as contingency allowance (Mak and Picken, 2000). Patrascu (1988) observed that "contingency is probably the most misunderstood misinterpreted and misapplied word in project execution. Contingency can and does mean different things to different people. Contingencies are crucial to achieving project objectives. Contingency funds are included in development budgets to provide managers with flexibility required to address uncertainties and deviations that threaten achieving objectives. According to Yeo (1990) the objectives of the contingency allocation are to ensure that budget set aside for the project is realistic and sufficient to contain the risk of unforeseen cost increases. Therefore, any realistic contingency must serve as a basis for decision making concerning financial viability of the variations, and a baseline for their control (Akinsola, 1996). Hart, (2007) highly recommended that owners develop an internal process to evaluate project contingency with a process of checks and balances and Risner (2010) suggested a contingency usage form to be completed and signed by both owner and architect as a way to control contingency usage. According to HM Treasury (1993) two major categories of contingency can be identified for construction projects; these are Design and Construction Contingencies. Design Contingency is for changes during the design process for such factors as incomplete scope definition and inaccuracy of estimating methods and data (Clark and Lorenzoni, 1985) while construction contingency is for changes during the construction

(Akinsola, Potts, Ndekugri and Harris (1997); Mak et al (1998); Mak and Picken (2000) and Bacarini, 2005).

Accuracy of construction contingency

The quantity surveyor's or cost engineer's estimate for a construction contract is only intended to predict the bid price of the contract and this must include (an allowance) contingency to account for change order growth or variations. According to Baccarini (2005) a comparison of predicted final cost against actual final cost indicates the accuracy of contingency. Broadly, the smaller the difference between these two costs the more accurate the contingency value. The contingency accuracy is expressed as a percentage of Award Contract value thus,

$$CA = \Sigma V\% - \Sigma C\%$$

Where CA = contingency accuracy, V% = variation% and C = contingency%

$$C\% = \frac{\Sigma C}{\Sigma ACV} \times 100$$

where ACV = Award Contract Value.

Omoregie and Radford (2006) established a minimum percentage escalation cost of projects in Nigeria at about 14% and advocated for an increase in contingency allowance from the present practice to about 15-20%. This is in agreement with Aibinu and Jagboro (2002) and also a percentage allowance recommended by the United States Department of Energy. In Baccarini's (2005) analysis of 48 road projects; the construction contingency averaged 5.24% while the average variation for all projects was 9.92% of ACV respectively. He concluded that the estimation of contingency is not fully reflecting the variability of contract variations – as the contingency accuracy is just, on the average, 52.82% of its actual purpose to cater for variations.

Application of contingency allowance to total estimated cost

Contingency amount set aside varies from project to project (Risner, 2010). According to Rowe (2006) different types of contracts contain different levels of change order risk and initial contingency guidelines should take the contract type into account.

Table 1: Example guidelines for initial contingency assignment.

Contract type	**Initial change order contingency (as a Percentage of Contract Cost)**
Procurement Only	5 per cent
Typical Construction	10 per cent
Special Construction	
Tunnels	15 per cent
Very Small Contracts	20 per cent

Source: Rowe (2006: 32).

Moselhi (1997) posited that contingency estimated with intuition and percentage addition ranges from 1 to 5% and rarely exceeds 10%. Parsons (1999) stated the purpose of contingency allowance is to improve the accuracy of cost estimates by compensating for inherent inaccuracies. This is provided for in form of contingency allowance. This is expressed as:

Total Estimated Cost (TEC) = Estimated Cost + Contingency Allowance.

DATA COLLECTION

The primary data for this study were obtained through structured questionnaire administered to experienced professional and practising quantity surveyors in client and consulting organisations. Purposive sampling was used in selecting respondents. Most of these organisations have projects across the country hence; they are representative of what obtains in the entire population of the study. The secondary data for this study were obtained from records of past projects in the organisations to get cost data variables required for research analysis. A data collection schedule was also used for the generation of cost data of past projects from the organisations. The schedule contains 14 variables extracted from the records of completed projects or on-going projects at completion. Mean Score, Descriptive statistics, Correlation, Regression, and Analysis of Variance (ANOVA) were used for the analysis of data. Inferences drawn were used to make conclusion on the effectiveness of contingency application in construction industry in Nigeria.

RESULTS AND DISCUSSION

A total of 70 copies of the questionnaires were administered to quantity surveyors and or cost expert in three different organisations in the construction sector. Fifty-three of the administered questionnaires were returned, representing 76% percent response rates. Thirty-four percent were from client's organisation while 66% were from consulting firms. The highest academic qualification of respondent is MSc. which constitute 18% of the responses, 47% are BSc. degree holder while the remaining 35% were HND holders. Majority of the respondents are professionally qualified with 60% being corporate members and 8% being fellow members of the Nigerian Institute of Quantity Surveyors. The remaining 32% were probationer members of the institute. This indicates that a large percentage of the respondents have adequate understanding of professional practice.

Estimating percentage contingencies

The research findings revealed that 0-5 percent contingency is mostly applied followed by 5 to 10 percent and application of contingency above10 percent is rare. Table 2 shows the ranking of the means of the common percentage figures employed by the cost experts.

Table 2:T Estimating percentage contingencies

Percentage of Estimate	Mean	Ranking
5%	3.40	1
7.5%	2.92	2
Below 5%	2.79	3
10%	2.64	4
12.5%	1.81	5
15%	1.47	6
20%	1.26	7
Over 20%	1.09	8

The result revealed that 5% is the mostly applied percentage followed by 7.5% and application of percentages below 5%. This confirms that more often than not quantity surveyors applied percentages that are less than 5% of the estimate. The estimation of 10% addition is in the same category with 7.5% and below 5%. The allocation of 20%

and above as contingency is almost nonexistent as their mean scores values are closer to '1' which represent 'never'.

Presentation and Analysis of Project Cost Data

Data were received from 21 organisations and included information relating to 99 projects of varying sizes and contract types. The following information was obtained for each project in the sample: Type of Client (1. Private; 2. Public); Nature of Project (1. New; 2. Refurbishment); Type of Project (1.Residential; 2. Industrial; 3. Health; 4. Educational; 5. Recreational; 6. Religious; 7. Office; 8. Others); Location of the Project; Lowest Bid; Consultant/Client's Estimate; Initial Contract Sum; Amount allowed for Contingency; Final Contract Sum; Planned Project Duration; Final Project Duration; Total Approved Variation; Total Amount of Approved Fluctuation; Gross Floor Area. The first statistical analysis carried out was the use of scatter plot diagram to identify outliers in which four projects were removed from a total of 103 projects which put the total number of projects for analysis to 99. The next step was to check the variability between the projects using analysis of variance (ANOVA) to detect whether the 99 sample size would not violate the assumption of homogeneity of variance and if the 99 projects are statistically significantly different. The variables used were total variation (including fluctuations) on estimated contract value (i.e. less contingency sum) and the contingency sum. The same analysis was carried out on the percentage of the variation on estimate and percentage of contingency on estimated contract value.

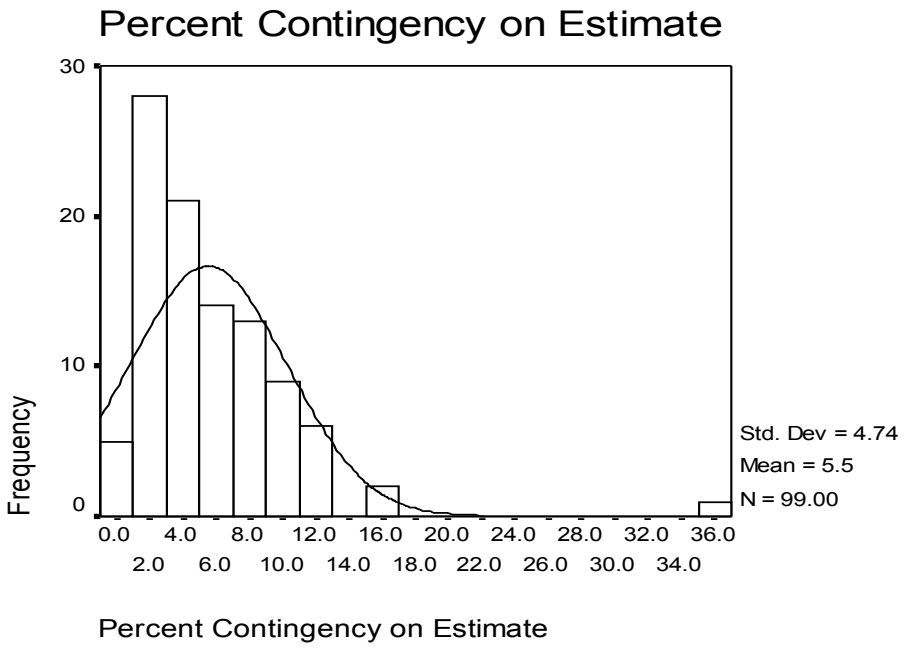

Figure 1: Histogram with Normal curve showing the distribution of Percentage Contingency on Estimate for the ninety-nine project data.

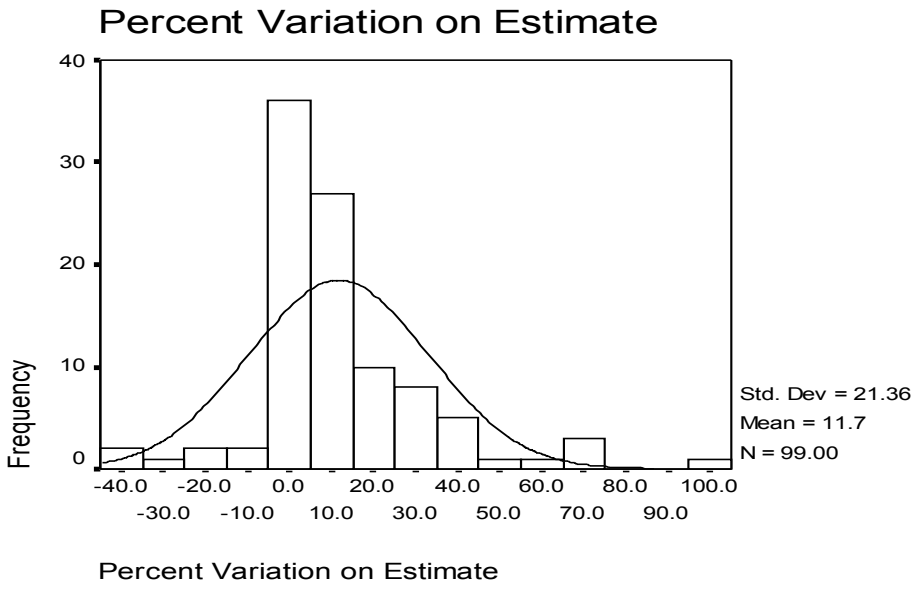

Figure 2: Histogram with Normal curve showing the distribution of Percentage Variation on Estimate for the ninety-nine project data.

The histogram of the line distribution of all the 99 project data of the two percentage variables is illustrated in Figures 1 and 2. A one-way between groups analysis of variance was conducted on the 99 sample projects in which the significant value (Sig.) for Levene's test indicated that the assumption of homogeneity of variance was not violated and the ANOVA table revealed that there is statistical significant difference between the projects.

Comparison of Contingency Sum to the Total Approved Variation

The variables C% for percentage of contingency on net estimated contract sum and V% which is percentage of variation on net estimated contract sum were calculated for each of the projects using Microsoft Excel to form two more variables for the SPSS analysis.

$$\text{Contingency C\%} = \frac{\text{contingency sum}}{\text{estimated contract sum}} \times 100$$

$$\text{Variation V\%} = \frac{\text{total variation}}{\text{estimated contract sum}} \times 100$$

Table 3: mean values of the percentage contingency (C%) and percentage variation (V%) on estimate

	N	Mean	Std. Deviation	Coefficient of Variation
			Statistic	
Percentage contingency on Estimate	99	5.53	4.788	86%
Percentage variation on Estimate	99	11.62	21.390	184%

The C% and V% were generated for the 99 variables and SPSS was used to analyse the descriptive statistics to generate the mean values of the percentage contingency

C% and percentage variation V%. The result of the descriptive statistics is as shown in Table 3.

The result reveals that construction contingency averaged 5.53% of the estimated contract sum and variation averaged 11.62%. To check for the effective accuracy of contingency in percentage: C%/V% x 100 = 47.59%. This indicates that contingency covered only 47.59 percent of approved contract variation and thus, did not cater for 52.41 percent of approved contract variation. The variability of variations (V%) of 184%, as measured by coefficient of variation (from standard deviation and mean), is much greater than the variability of construction contingency (C%) which is 86%. This is a significant difference which was earlier indicated by the ANOVA results. An important observation is that percentage contingency is less than the total variations on the project and it is estimated at about half of its expected value. This result validates the research hypothesis that Contingency sum is less than the total approved variation and fluctuation.

Figures 1and 2 indicated important information which is relevant to the research work. Having discovered the average percentage of contingency and variation on the projects, the range of percentage contingency and variation is analysed. Table 4 sets out the summary of the findings. The analysis revealed that 0-5% contingency is applied for about 58% of projects followed by 5.01% to 10% which covers another 32% of the projects. Contingency of 10.01% to 15% was applied to 7% of the projects.

Table 4: Percentage range of contingency on estimate

Contingency Percentage	No. of Projects	Percent
0 to 5%	57	58
5.01 to 10%	32	32
10.01 to 15%	7	7
15.01 to 20%	2	2
>20%	1	1
Total	99	100

About 15.01- 20% was applied to just 2% of the projects and only 1 (1%) out of 99 projects has a contingency allocation of over 20%.This analysis also strengthens the opinion of the respondents that the most applied percentage contingency ranges between 0 and 5 per cent. This suggests that there is an agreement between analysis of the project cost data and the opinion of the respondents on the range of percentage used in the estimation of contingency.

Table 5: Percentage range of variation on estimate

Variation Percentage	No. of Projects	Percent	Cumulative Percent
> -20%	5	5.1	5.1
-10 to -15%	1	1.0	6.1
-5 to -10%	3	3.0	9.1
-0 to -5%	9	9.1	18.2
0 to 5%	27	27.3	45.5
5 to 10%	19	19.2	64.6
10 to 15%	3	3.0	67.7
15 to 20%	8	8.1	75.8
>20%	24	24.2	100.0
Total	99	100.0	

Invariably, the revelation of the research is validated within the research by comparing respondents opinion and project cost data and, consistently reliable with other research findings. In comparison, the range of the percentage variation on these projects was also calculated so as to ascertain how well the contingency was able to predict the eventual variation on the projects. Table 5 sets out the results of variation (V%) of the 99 projects. It was revealed that in 18 of the 99 projects, the estimated contract sum was reduced by variations (negative variation) and, 36 (9+27) projects have their variations between 0 to ±5%. Thus, in aggregate contingency allowance has been effective in accounting for variation or in avoiding cost overrun in 36% of the projects. An important observation of concern is the number of projects that have variations greater than 20%, 24 projects (24.2%) were in this category.

From the foregoing the accuracy and or effectiveness of contingency can be stated as the difference between the percentage variations and percentage contingency on the projects. That is, 11.62% - 5.53% (from Table 3) which gives 6.09%, a result that is even higher than the percentage contingency. Hence, contingency sum is less than the total approved variation. The research also validates the general opinion that contingency is less than total approved variation in a contract as construction contingency averaged 5.53% of the estimated contract sum and variation averaged 11.62%. This indicates that contingency covered only 47.59 percent of approved contract variation and thus, did not cater for 52.41 percent of approved contract variation. Interestingly, the reverse seems to be the case for road projects as Baccarini (2004) reported that contingency covers 52.82% of approved contract variation but did not cater for 47.18%. He also reported that construction contingency averaged 5.24% while the average variation for the projects was 9.92% of actual contract value respectively. Omoregie and Radford (2006) established a minimum percentage escalation cost of projects in Nigeria at about 14 percent, a slightly higher figure than 11.62% average revealed by this study.

Test of hypothesis

H1: Contingency sum is less than the total approved variation and fluctuation.

The analysis in Table 3 and preceding discussions indicated difference in contingency sum and total approved variation. The stated hypothesis is confirmed and accepted that contingency sum is less than the total approved variation by 6.09% but how significant. A One-way ANOVA with post hoc test was carried out to establish if there is a significant difference between contingency and the variations (including fluctuations). By this the research establishes the effectiveness of contingency on project delivery, if the difference found is significant.

A one-way between group analysis of variance was conducted to explore the effectiveness of contingency on variation, as applied to all the 99 projects in the study. There was a statistically significant difference at the $p < 0.001$ in the two variables [F(42, 56)=6.02, p=0.01]. The effect size calculated using eta squared was 0.82 which indicated a very large effect. The summary of the results is displayed in Table 6.

ANOVA

Table 6: Statistical difference between total variation and contingency

	Sum of Squares	Df	Mean Square	F	Sig.
Between Groups	526208.063	42	12528.763	6.021	.000
Within Groups	116519.603	56	2080.707		

Total	642727.665	98

Significant at $p<0.001$

The result of the analysis indicates that contingency allocated is not producing the result that is intended on project delivery hence, contingency applied on projects is not effective.

CONCLUSIONS AND RECOMMENDATIONS

The study revealed that construction contingency averaged 5.53% of the estimated contract sum and variation averaged 11.62% which means that total approved variation is more than the contingency sum allowed by about 6.09%. Statistical result of the analysis indicated that contingency allocated is not producing the result that is intended on project delivery hence, contingency applied on projects is not effective. This is a problem to be solved in order to accurately forecast the final cost of any contract at any given time. The importance of forecasting an accurate and effective construction contingency is sine qua non to client's satisfaction on the estimated final construction cost and hence, the construction contract delivery. Contingency sum should be understood as the fund for the client or project manager's authority hence, quantity surveyors should not entertain any fear forecasting. This study recommends a percentage contingency allowance of about 12% to cater for variations on contract delivery. The notion that whether or not there is enough contingency, variation would arise should be discarded. A more proactive and scientific estimating and managing a defendable and reliable contingency that records a reasonable savings at completion of the project should be embraced.

THE NEED FOR PROFESSIONAL PROJECT MANAGERS IN THE CONSTRUCTION INDUSTRY IN SWAZILAND

Sidumo Dlamini[1] and Hendrik Prinsloo[2]

[1.2] *Faculty of Engineering, Built Environment and Information Technology, University of Pretoria, South Africa*

ABSTRACT

The construction industry is one of the most significant contributors to Swaziland's GDP. Traditionally civil engineers, architects and quantity surveyors have assumed leadership in the design and supervision of projects but with the advent of project management as a profession the shift to having a project manager as a specialist independent consultant has not been fully embraced nor appreciated in the construction industry. Most professionals still double as designer and project manager even though a majority of these professionals lack basic training in project management. This paper assesses if there is a need for project management to be formally established as a profession in the construction industry in Swaziland. The current performance levels of professionals working as project managers were investigated. Information was also gathered on the type of qualification of professionals involved in the project management of construction projects. The paper assessed stakeholders' perception in terms of the need for qualified project managers to be involved in major construction projects. Questionnaires were utilised to collect primary data from respondents (project management consultants, municipalities and the Ministry of Public Works and Transport and private sector stakeholders). The findings of the research showed that the current performance levels and qualifications of project managers are not satisfactory. It was found that a need exist to establish project management formally as a profession in the construction industry.

Keywords**:** Project management, professional registration, Swaziland.

INTRODUCTION

According to the Facilities Management Institute (2005) in the next ten years, the following factors will influence the construction market: customer sophistication, construction skills, construction services, globalisation, consolidation, construction diversity, capital supply, restoration, governance and technology. This demands highly efficient personnel to adequately address the needs and wants of the clients who too are expecting quality services at lower prices. Beard, Loulakis & Wundram (2001) and Konchar & Sanvido (1998) argue that architects and engineers within the construction industry are faced with newer management challenges in business. Many of these challenges are driven by technology associated with building materials, newer design methodologies, design economies and greater sophistication, along with clients' requirement to receive a low-cost, quickly constructed, high-quality and safe project. Traditionally engineers, quantity surveyors and architects have been expected to perform technical and project management roles during the construction phases. Currently the construction projects being undertaken in Swaziland are becoming bigger and more complex. The Kingdom of Swaziland is a small landlocked country of just over 17,000 square kilometres and is about the same size as Wales with a population of approximately 1.3 million people. This article aims to establish if there is need to formally establish project management as a profession in the construction industry in Swaziland. Due to the fact that no similar studies have been conducted the purpose of this study is to make a preliminary assessment that can be utilised for future studies.

Murphy, Bruce & Dalmar (1974) argues that project management and effective leadership continue to impact the success or failure of a project. As any project's success is generally defined on the basis of time, cost and quality performance we cannot diminish the impact of key individuals on the project's ultimate success.

THE CONSTRUCTION INDUSTRY IN SOUTHERN AFRICA

The Department of Public Works South Africa (2005) states that the majority of Southern African Development Community (SADC) countries, including Swaziland, were former colonies of the British Empire. Hence their construction industries are primarily modelled on the British Construction Industry (BCI). The BCI model is characterised by the so-called 'one-off' approach. This is the traditional approach, characterised by the maximised fragmentation of responsibilities between participants and by sequential intervention of the participants in the different phases of a construction project.

The primary professionals involved in this model:

- Engineers (civil, structural, building services and mechanical);
- Architects (principal and landscape);
- Quantity surveyors;
- Construction managers and
- Construction project managers.

According to Smallwood and Rwelamila (1996) the causes for poor performance in the Southern African construction industry are: inadequate training, lack of management expertise, little worker participation, absence of quality management systems and improvement processes. Consequently, not having project managers

during the construction process can result in the above mentioned problems and others. Angelides (1999) argued that like all other human activities project management has to take place within constraints such as scope, time and costs. These constraints have increased the need for an individual who can coordinate and help co-operate the efforts of all the parties involved in the construction process. Cicmil (1997) argued that success (of projects) requires more than just the proper scheduling and budgeting.

According to Department of Public Works South Africa (2005:33-34) there are many primary impediments, which are being experienced by all SADC construction industries. Some of these are:

- Lack of appropriate construction industry policy (only two countries have policies; these are South Africa and Tanzania).
- Artisan, supervisory and management capacity is diminishing.
- The public sector's inability to manage its procurement function has given rise to delivery bottlenecks, which escalate the cost of development to both industry and public.
- Poor quality of work and low level of productivity.
- Project managers do not have appropriate management structures to balance cost, quality, schedule and utility requirements.
- Costly projects delays due to division between design and construction
- Lack of coordination between built-environment professionals.
- Project documents are often late to arrive on site; they are incomplete and contain large sections of irrelevant material.
- A considerable amount of unacceptable quality work arises due to lack of organisation and coordination between trades, which affect location, accuracy, finish, sequence, damage, etc.
- The architect / engineer appointed by the client are inadequately experienced to cope with the coordination of the design team, to lead the design effort and to coordinate the interface between design and fabrication.

THE CONSTRUCTION INDUSTRY IN SWAZILAND

The construction industry in Swaziland falls under the Ministry of Public Works and Transport which is responsible for construction and maintenance of government buildings, construction and maintenance of public roads, administration of Road and outspan act, planning and regulation of road and transport services. The Ministry's mandate is to ensure the provision and maintenance of a sustainable public infrastructure and regulation of a vibrant construction industry and transport. (Ministry of Public Works and Transport, Swaziland, 2007). The construction industry in Swaziland is one of the vibrant and significant industries and many people are employed in this sector, which has contributed to 6.8% of GDP in 2004/5. (Swaziland year book, 2005)

CONSTRUCTION PROJECT MANAGEMENT

Definition of project management

In order to understand the state of construction project management in Swaziland, one has to first understand what project management is and why it is of importance in the built environment professions.

PMBOK (2004) defines Project Management as "the application of knowledge, skills, tools and techniques to project activities in order to meet or exceed stakeholders' needs and expectations."

Kerzner (2006:4) defined Project Management as the "planning, organising, directing and controlling company resources for a relatively short-term objective that has been established to achieve a specific set of goals and objectives."

From the above definitions it is clear that project management encompasses many variables and is complex in nature yet very essential for the timely completion of projects.

Benefits of Incorporating Project Managers in Projects

Burke (1999:8) states the benefits of a project management approach, obviously follows on from addressing the needs of the project. The project manager is responsible for developing a plan through which the project can be tracked and controlled to ensure the project meets the pre-set objectives. Mullaly (2002) states that the role of a project manager is not only managing, but more importantly managing the boundaries themselves. It is this shift in thinking that defines the project manager as an organisational leader. Even on the smallest project, the potential impact of a project manager is significant. Managed well, and the positive impact on the organisation can be exceptional, while the impact of failed project can be devastating.

RESEARCH METHODOLOGY

Questionnaires were mainly used to collect primary data from respondents (project management consultants, companies and the Ministry of Public Works and Transport). This study utilised both qualitative and quantitative methods. Secondary data sources such as books and journals were also utilised.

Research type

Leedy (1997) describes non-experimental quantitative research as "involving careful descriptions of observed phenomena and or exploring the relationships between different phenomena". Different types included in this broad heading are descriptive survey, longitudinal (developmental), correlational and ex post facto research designs. This study used a non-experimental quantitative research methodology.

Sample selection

The researcher distributed twenty questionnaires. The sample size was deemed sufficient taking into account the total population of Swaziland is approximately 1.3 million people and only a small percentage of people are involved in the construction industry as project managers. Questionnaires were distributed to most consulting firms involved in the construction industry in Swaziland. Eleven questionnaires were received back from the different respondents.

Research limitations, scopes and boundaries

The study only focussed on Swaziland and did not assess the need for professional project management in any of the other SADC countries

FINDINGS AND DISCUSSION

The main problem

The main objective of the study is to determine if there is a need for the establishment of project management as a profession in the construction industry in Swaziland.

 ISBN: 978-1-84219-840-7 .

The First Sub-problem & findings

The first sub problem investigated the current level of project management performance in the construction industry in Swaziland.

The findings showed that 86% of the projects exceeded the initial completion date by at least 3 months. A third of those (29%) shows that projects even exceeded initial completion date by a year.

30% of project managers interviewed had full control over the budget while 40% supplied estimates and participated in its distribution and 10% supplied the estimates but did not get involved in the distribution of the budget. 20% neither supplied the estimate nor participated in the distribution of the budget. However, the findings of the research showed that only 50% of the projects were completed within budget.

62.5% of the stakeholders that engaged the services of qualified project managers for their projects were satisfied with their performance and the end product. Given the fact that only 25% of project managers had a formal qualification in project management, one would argue that if stakeholders were to use more qualified project managers, more projects will be finished timeously, within budget and with satisfied stakeholders.

The very high number of cost and time overruns on projects recorded in the findings is a clear indication that serious problems exist in the management of construction projects in Swaziland. There is a dire need for intervention to improve the current situation.

The Second Sub-problem

The Second Sub-problem set out to determine the qualifications and background of the consultants acting as project manager in the construction industry in Swaziland.

75% of consultants that are involved in project management do not have a formal project management qualification. 64% of professionals in the construction industry are not affiliated with any professional regulatory body.

The third sub problem

The third sub-problem tested stakeholder perceptions in terms of the need for qualified project managers in Swaziland.

The response of the stakeholders depicts a mixed picture of their understanding of project management, a project manager and their use of project managers in running their projects. Figure 1 below indicates that 37.5% of stakeholders prefer to use qualified project managers, 37.5% of stakeholders do not insist to use qualified project managers and 25% sometimes use qualified project managers.

Figure 1: Use of Qualified Project Managers by clients

Considering the results it is evident that the use of qualified project managers is not an essential requirement for the success of projects in the mind of the client.

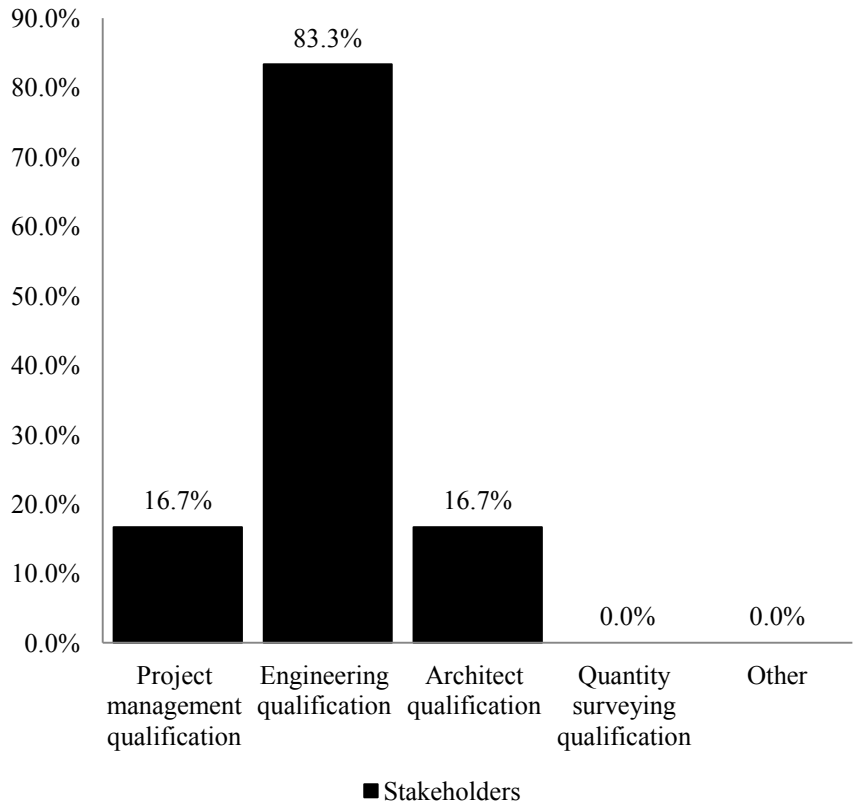

Figure 2: Criteria used in selecting Project Managers

Figure 2 show that most of the people get assigned project management duties by stakeholders by virtue of being professionals who were involved in the design stages of the project.

CONCLUSIONS

The research concluded that performance of project managers in Swaziland is very poor with 86% of projects being completed after the planned completion date and 50% of projects exceeding the original budget. 75% of project managers involved in these projects did not have a formal project management qualification and 64% of professionals involved were not affiliated with any professional regulatory body. The findings also showed that project management is not fully understood as a profession, separate from other fields in the construction industry in Swaziland. It is clear that the establishment of project management as a formal profession in the construction industry in Swaziland will have many benefits. At the very least it will ensure that properly qualified professional would be at the helm of projects resulting in the improvement of project performance.

The following recommendations can be made based on the findings of the research:

- The Ministry of Public Works and Transport should spearhead the establishment of project management formally as a profession.
- There is need for all stakeholders to be educated on the roles and uniqueness of project management and project managers.
- There is also a great need to assess qualifications of project managers and to ensure that the right certification is produced before someone can be declared a project manager.
- Every professional in the construction industry needs to be taught about the role of project managers especially how they are different from other professionals in the industry.

THE READINESS OF THE WELSH CONSTRUCTION SECTOR FOR MANDATORY BIM

Dr Emmajane Mantle[1] and Trefor Williams [2]

[1] *University of Glamorgan, Faculty of Advanced Technology*
[2] *University of Glamorgan, Faculty of Advanced Technology*

ABSTRACT

The Construction sector in England is having to come to terms with the requirements of Government legislation aimed at improving its efficiency by 20%. At the heart of this initiative is the requirement for all projects in England to utilise BIM by 2016. The Welsh Government has devolved powers and has a number of social policies which are aimed at developing SMEs and encouraging community gains from construction projects. A seminar for construction professionals was organized by Constructing Excellence Wales to elaborate on the English directive and to consider an example of BIM in use on a Welsh project. This seminar provided the authors with the opportunity to seek the attendees' opinions in relation to their current understanding and use of BIM, their attitude to the English targets and how they thought compulsory BIM might impact on the local supply chain. The results indicate that there is a readiness for implementation in Wales however there is also a concern that its mandatory implementation on public projects could have a negative impact on Welsh companies, in particular SMEs.

Keywords**:** BIM, Community Gains, SME, Wales.

INTRODUCTION TO BUILDING INFORMATION MODELLING (BIM)

BIM involves representing the entire building in the form of a comprehensive 3D model with all the building elements defined parametrically, together with its associated database information (Lo, 2009). (Cerovsek 2011) described BIM as a digital representation of an actual building for project communication over the whole building-project lifecycle. A physical, tangible appearance of a building from a time standpoint can be represented by three model categories: 'as-it-was', 'as-it-is', or 'as-to-be'.

The use of BIM allows for all information provided by other areas of the appointed Construction Team, such as the Electrical and Mechanical elements, Structural elements, the Costs and Management of Materials, and the Fittings and Fixtures used,

[1] ejmantl1@glam.ac.uk
[2] twilliam@glam.ac.uk

the BIM Model becomes an identical virtual model of what will be built. By making use of the same Model throughout the supply chain reduces the need for duplicating work. There is a large level of risk associated with the duplication of information for convenience sake, mostly because it creates difficulty for the user to discern whether that specific information is in fact the latest available. (Kymmel 2008) insists that information should exist only once rather than be duplicated unnecessarily for convenience of individual access.

The ability to keep information up to date and accessible in an integrated digital environment gives architects, engineers, Contractors, and owners a clear overall vision of their projects, as well as the ability to make better decisions faster (Anon, 2011). This in turn raises the quality and profitability of projects (Van Zyl, 2010). From this information it is possible to conduct a 2D and 3D analysis, allowing the Client and the Design/Construction Team to view the 3D model in its environment, and produce 2D Plans and Elevations to print, along with 3D Still Imagery and Animation. It is also possible to extract 4D Data (Time) from the Model to be analysed in a Software to generate accurate Schedules and Time Simulation of the proposed Building. It is also possible to extract 5D Data (Cost), by using the data within an Estimating Software Package to generate accurate Material Quantities and Costs. Furthermore it is possible to use the BIM model, and variations to the BIM model, to analyse the energy efficiency and sustainability issues of the designs, and through the BIMs abilities to link into Facilities Management software it will further be possible to continuingly use the BIM model Post Hand-over, to maintain the Asset and its Facilities, according to the Manufacturers details, as provided within the model.

Seeing the benefits of BIM, software developers have been producing software that can be 'plugged' into the BIM packages, therefore increasing performance and interoperability with other applications to allow for file transfer and collaboration within the Construction Team. These applications have helped to enhance the performance of the Modelling platform by incorporating functions such as Visual Estimating, Scheduling, Time Simulation and Clash Detection, Energy Analysis, Design and Design Change Analysis.

The capabilities of BIM have also been recognized, and discussed in the UK Government's 'Construction Strategy' Report. Its adoption therefore is being driven by Government departments and large development agencies, including General Services Administration (GSA) (Van Zyl, 2010).

UNITED KINGDOM (UK) GOVERNMENT STANCE ON BIM

The United Kingdom (UK) Government has recently published its Construction Strategy in which it states *There is widespread acknowledgement across Government and within industry – backed by recent studies – that the UK does not get full value from public sector construction; and that it has failed to exploit the potential for public procurement of construction and infrastructure projects to drive growth.*
(Cabinet Office 2011 p3)

The document also challenges the UK construction industry to work more collaboratively, increase innovation in the supply chain and reduce costs by up to 20% by 2015.

The UK construction sector contributes approximately 7% of GDP and is worth about £110 billion per annum which comprises three main sub-sectors: commercial and social, £49 billion (£20bn public, £29bn private); residential, £42 billion (£14bn public, £28bn private); and infrastructure, £18 billion (£7bn public, £11bn private). The industry is highly fragmented, with over 300,000 businesses (of which 99.7% are SMEs) and it employs over 2 million workers. (Cabinet Office 2011)

The document recognises that the UK industry has reduced the fragmentation of the supply chain since the publication of the Latham and Egan reports particularly in relation to long term framework agreements. However it also states that "*there is a tension between the benefits of working with fewer suppliers in long-term relationships, the desire to maintain a market that is accessible to new entrants (particularly SMEs) and the risk of locking out competition and innovation*." (Cabinet Office 2011 p6). This concern regarding the impact on SMEs is supported in the findings of a recent survey which found that 75.5% of SMEs think their size prevents them from winning public sector contracts (Glackin 2012). It also found 94% of contractors believe the government had failed to include SMEs in its procurement system.

Another significant strand of the Government's policy is the requirement for greater use of BIM for the delivery of their construction projects. In 2011, the Government's chief construction adviser, Paul Morrell indicated that BIM is to become compulsory in England for all publicly-procured projects over £50 Million by 2016. Since this announcement the threshold has gradually reduced so that nearly all publicly funded projects in England will be required to utilize BIM by 2016. The mandatory requirement of BIM will be a phased process working closely with industry groups, in order to allow time for industry to prepare for the development of new standards, and for training (Cabinet Office, 2011).

Levels of BIM

The development of a BIM Maturity Model (see Figure 1) illustrates the different levels of within the development of a BIM Process. The current target set by the Government for publicly funded projects is that they must be delivering Level 2 of the model illustrated below.

 ISBN: 978-1-84219-840-7 .

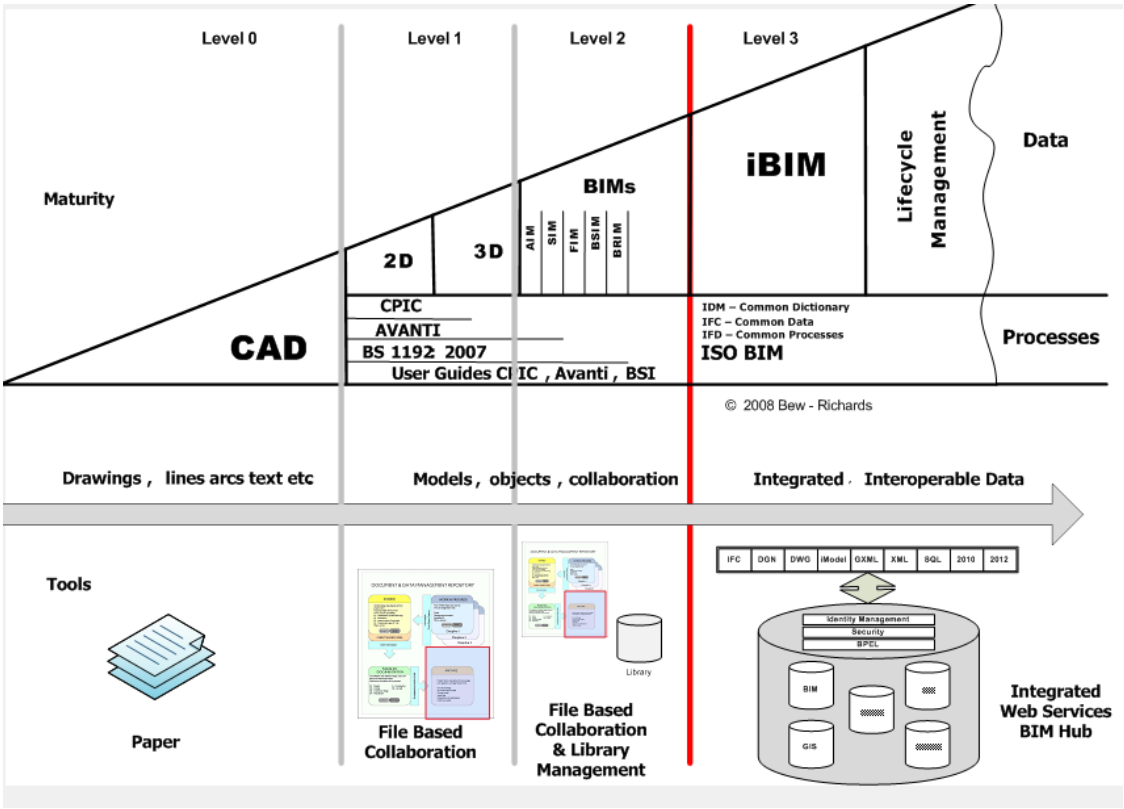

Figure 1 BIM Maturity Levels (BIM 2011 p16)

The first Level: Level 0, represents the traditional methods of developing and printing 2D Plans and Elevations using CAD Software packages such as AutoCAD. Level 1 a managed 2D or 3D CAD environment with a collaborative tool providing a common data environment with a standardized approach to data structure and format. Level 2 where separate BIM Models are created by the different disciplines and merged into one model via compatible software. The final Level: Level 3 represents a wholly collaborative BIM Process where the BIM Model is created and made available via a 'Cloud' so to be used by other Team members so that other industry specific details, such as the structure and mechanical information can be inputted, data is shared through the use of file formats such as IFCs via an Internet Cloud.

The adoption of BIM will call for a profound change in the relationship between public authorities and the construction industry, to ensure the Government consistently gets a good deal, and the country gets the social and economic infrastructure needs for the long-term. The result of this will mean that the public sector will become a better Client - more informed and better co-ordinated when its requirements are specified, designed and procured. The strategy also challenges industry business models and practices. It will replace adversarial cultures with collaborative ones; and will demand cost reduction and innovation within the supply chain to maintain market position – rather than innovation that is focused on the bidding process - with a view to establishing a bargaining position for the future (Cabinet Office 2011).

Van Zyle (2010) believes that BIM is here to stay, and stated that as developers and Government Departments are insisting on the use of BIM to complete new projects, that it will soon be almost impossible to win tenders if you are unable to provide some form of BIM to the Client. Since the acknowledgement of the Government of the

 ISBN: 978-1-84219-840-7 .

importance of the use of BIM within the Construction Process it is inevitable, and imperative that this process will soon become widely used throughout the UK, and globally.

GOVERNMENT IN WALES

Since devolution in 1999, many policies and services are different in Wales compared to the rest of the UK. The National Assembly for Wales and the Welsh Government are responsible for most of the issues, including health, education, economic development, culture, the environment and transport.

A comparison of UK, England and Wales construction sectors (see Table 1) indicates the following:

	UK	**England**	**Wales**
Construction firm 1-13 employees	91%	91%	90%
New orders 2010	51% Public 49% Private	50% Public 50% Private	45% Public 55% Private

Table 1 Comparison of UK, England and Wales (UK National Statistics 2012)

The simple statistics indicate that there is a great similarity in the relationship between private and public spending and the number of SMEs delivering that workload.

As part of its devolved powers the Welsh Government has several policies to recognise the importance of SMEs to the economy of Wales. Two examples of these devolved social policies are Opening Doors (Welsh Government 2008), which is a procurement strategy for the public sector in Wales aimed at addressing the concerns of SMEs, and Community Benefits (Welsh Government 2010) which is aimed at providing opportunities for small organisations in Wales, such as SMEs and Third Sector Organisations.

METHODOLOGY

A seminar for construction professionals was organised by Constructing Excellence Wales to elaborate on the English directive and to consider an example of BIM in use on a Welsh project. As part of this study a questionnaire was developed and distributed to attendees of this seminar. The aim of this research was to establish the readiness of the Welsh construction sector to implement the targets for BIM implementation imposed in England. In order to achieve this aim a questionnaire was developed to establish:

1. Current understanding and use of BIM in Wales
2. Attitudes to the targets set for England
3. Perceptions of how BIM might impact on the supply chain.

 ISBN: 978-1-84219-840-7 .

Of the 80 attendees 60 completed the questionnaire.

RESULTS

Although the event focused on BIM, 3% (2) of the 60 respondents were still not aware of BIM and a further 62% (37) were Aware and planned to adopt the process in the future. The remaining 33% currently used BIM within their Company.

Of those who currently use BIM, the participants were asked to select for what purpose it was used. The choices provided included: 3D Visualisations (44%, 17), Scheduling (38%, 15), Budgeting (3%, 1), Sequencing (0), Creating a Bill of Quantities (5%, 2) and an 'Other' selection box (10%) which consisted of Research and software distribution.

The participants were asked to consider a range of possible outcomes that BIM might provide. Table 2 shows the percentage of the overall group who selected each outcome. The main positive outcomes selected were "Better collaboration within team", "Clashes detection" and "Greater predictability of time and cost". The main negative outcomes selected included "High cost of hardware and software" and "Uncertainty re legal situation". Only 30% thought that it would "Disadvantage smaller companies".

	Total	Percentage
Better collaboration within team	49	82%
Clash detection	46	77%
Greater predictability of time and cost	44	73%
Increased costs associated with training and updating skills	37	62%
More effective whole life management of properties	36	60%
Reduced waste	35	58%
Faster project delivery	33	55%
Continual improvement	33	55%
High cost of hardware and software	32	53%
Reduction in health and safety risks	30	50%
Better environmental performance/sustainability	29	48%
Uncertainty re legal situation such as liability for errors, ownership of design copyright etc	26	43%
Easier to obtain planning permission for schemes	18	30%
Disadvantages smaller Companies	18	30%
Longer design periods	16	27%
Higher costs to produce project information	13	22%
Other	2	3%

Table 2 What is BIM likely to provide?

In regards to the targets set out by the Government for the implementation of BIM in England, the participants were asked to comment if they believed that Wales should follow the same targets as England. The results indicate that 67% (40) believed that Wales should follow the same targets set out for England. A further 25% (15) agreed with the target but thought that there should be some modification before implementation. The modifications proposed were 11 respondents wanted more time to implement whereas 8 respondents felt that BIM should only be applied to projects over £5 million in value.

As previously discussed, the majority of businesses in Wales are small companies with fewer than 13 employees. The participants were asked to consider the impact of mandatory BIM on the supply chain. The results showed that 52% of respondents thought that "Fewer SMEs would be able to bid for their contracts" and 40% thought that "Fewer local companies would be able to bid for their contracts".

CONCLUSIONS

The United Kingdom (UK) Government has recently published its Construction Strategy in which it challenges UK construction industry to work more collaboratively, increase innovation in the supply chain and reduce costs by up to 20% by 2015. As part of this strategy BIM is set to become compulsory in England for all publicly-procured projects by 2016 at Level 2 maturity. However there is also recognition of the tension that long term collaborative agreements introduce into the Supply Chain relationships, particularly for SMEs.

 ISBN: 978-1-84219-840-7 .

Since devolution in 1999, many policies and services are different in Wales compared to the rest of the UK. As part of its devolved powers the Welsh Government has several policies to recognise the importance of SMEs to the economy of Wales. Statistics indicated that there is a great similarity in the relationship between private and public spending and the number of SMEs delivering that workload.

The objectives of this study were to establish:

1. Current understanding and use of BIM in Wales

   The majority of respondents were aware of the BIM process, and just over half already utilized BIM on their projects. The main uses of BIM included: 3D Visualisations (44%, 17) and Scheduling (38%, 15),

2. Attitudes to the targets set for England

   The majority of respondents believed that Wales should follow the same targets set out for England, however a significant minority thought that more time was needed before implementation.

3. Perceptions of how BIM might impact on the supply chain.

   The main positive outcomes selected were “Better collaboration within team”, “Clashes detection” and “Greater predictability of time and cost”.

   However the results also showed that the majority of respondents thought that the mandatory implementation of BIM would result in fewer opportunities for SMEs to bid for work. There was also a significant number of respondents who felt that local companies would be disadvantaged in the bidding process for contracts.

Overall the survey indicates that the existing knowledge and utilisation of BIM within the sample suggests that there is a readiness for implementation. The results also indicate that the Welsh Construction sector is prepared to work to, and deliver the same expectations as those currently imposed in England. However there is a concern that the mandatory implementation could have a negative impact on welsh companies, in particular SMEs which may contradict some of the social agenda policies set by the Welsh Government.

TOWER CRANE POSITIONING: A 3D SPREADSHEET OPTIMIZATION MODEL

Abdelhay Mohamed[1], Ossama Hosny [2], Ahmed Elhakeem[3], Amr Elhoteiby[4], and Ahmed Fayad[5].

[1,2,3,4,5] *School of Science and Engineering, the American University in Cairo, Cairo, Egypt*

ABSTRACT

Positioning of tower cranes in construction sites is a crucial yet challenging task in project planning which affects cost, duration, and productivity of projects. Nowadays, although skilful planning engineers carry out this step in site layout planning, they face many problems to achieve the optimum layout design and optimum positions of cranes. This paper aims to develop a decision support system for engineers to help them in selecting the optimum positions for tower cranes in construction sites using Genetic Algorithm (GA). The system input parameters include: site area, construction temporary facilities, buildings locations and heights. In addition, the number, type and range of the available tower cranes as well as their hook velocity and required material loads to be moved horizontally and vertically for each facility are required parameters. The objective is to achieve the minimum crane travel time between temporary construction material warehouses and different construction zones in the site. This minimizes projects construction costs and duration. The output of the model application is the number of tower cranes needed and the proposed position of each tower crane.

Keywords: genetic algorithms, optimization, productivity, site layout, tower crane.

INTRODUCTION

In construction projects, limited spaces are available to build complicated and tall buildings. In addition, construction engineers usually focus on increasing the speed of construction activities to satisfy projects stringent deadlines. It is usually the case that the shorter the project duration, the higher the profits are. In construction of complicated and tall buildings, multiple tower cranes are usually used. As a result, the position of each tower crane needs to be optimized to avoid conflicts in construction site. According to Alkriz and Mangin (2005) site layout planning has a crucial impact on the overall productivity and cost efficiency. Usually, tower crane positioning is carried out by construction managers based on their own experiences using trial/error, without a systematic approach that ensures appropriate crane positioning. Therefore,

[1] abdelhay@aucegypt.edu
[2] ohosney@aucegypt.edu
[3] aelhakeem@aucegypt.edu
[4] amr_h@aucegypt.edu
[5] ahmed.fayad@aucegypt.edu

the outcome of site layout may seem to be well organized but not optimized and may lead to increases in cost and waste of labour time and materials.

Rodriguez-Ramos and Francis (1983) handled the problem of positioning a single tower crane hook while waiting to be requested to deal with another load. They developed a mathematical model to reach the exact position of the tower crane to minimize the duration. On 1991, Choi and Harris developed a mathematical model targeting positioning single tower crane where it can minimizes the travel time of the tower crane. Zhang et al. (1996) established a model based on probability to optimise the location of a single tower crane. This model misused the relation between construction zones and the tower crane that consequently affect the optimum position of the tower crane. Leung and Tam (1999) established an Artificial Neural Network (ANN) combined with Multiple Regression Analyses (MRA) model that predicts number of erecting times of the tower crane.

This research introduces a spreadsheet crane-positioning model that optimizes the position of travelling tower cranes and the applicability to be used in the desired construction site. Genetic Algorithm is used to generate potential solutions by applying normal crossover and mutation operators, together with a suitable fitness function to reach the minimum travel time of tower cranes.

An overview of the Genetic Algorithm GA in the construction industry

Genetic Algorithm (GA) was applied to many construction management problems. For example, Genetic Algorithms-based simulation modelling was used to develop a crew allocation system (Al-Abazi, A. and Dawood, N., 2010). They developed a model assisting planners to allocate labours and facilities in construction site so that the project manager could minimize the cost, and consequently increase the profit margin.

In addition, Genetic algorithm was used to find the most beneficial agreement for contractors and suppliers (Dzeng, R. and Yu-Chun, L., 2003). Web-based development was used to improve negotiation efficiency that helps a contractor and suppliers to negotiate via the Internet. This would help both contractors and suppliers in finding good agreement that satisfy their needs.

Problem definition

Due to the complexity of current construction projects and the variety of the facilities in any construction site, planners are facing many challenges to find the optimum site layout and the position of tower cranes to facilitate material and loads transfer among project facilities. The optimization of tower cranes positions became more complicated with rapid technology improvement as travelling tower cranes are being used. As a result, planners started to find a new way to facilitate site layout planning and positioning of tower cranes so that they could reach the desired outcome of using tower cranes with minimum cost and maximum usability.

The main objective of this research is to develop a model that assists planners to find the optimum position of tower cranes by evaluating the weight of each solution and finding a site layout solution that has the highest score. This is achieved by utilizing a set of input data; a fitness function and consequently the output would be the number of tower cranes needed, and the position of each tower crane. This model is illustrated

using a tower cranes design equations where the objective is set to minimize the travel time of all tower cranes. These equations are used to calculate the time for each motion of the cranes that will, consequently, help in calculating the total travel time of the tower crane.

Model description

In this paper, facilities and tower cranes will be assigned by their coordinates. The coordinates will be in Cartesian (x, y) format. All facilities are assumed to be rectangular and the tower cranes will be indicated as circles (plan view) (see Figure 1). The dimensions of facilities will be provided as inputs. The crane type is defined by its radius and the load/radius curve (see Table 1).

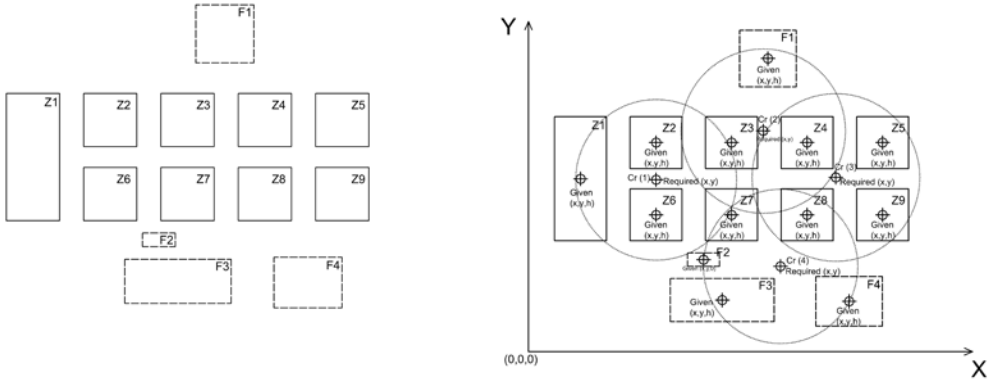

Figure 1- Site Layout and applying Cartesian coordinates

The distance between any facility and the crane should be less than the crane radius. In addition, the load carried from the facility should be less than the load from the radius/load curve. Also, the tower cranes should be placed outside the parameter of the construction site (Zones).

Table 1- Load/radius curve, Alkriz, K. 2005

Radius (m)	1-23	24	25	29	30	33	35	39	40	43	45
Max. Load (Kg)	4000	3815	3630	3030	2910	2590	2400	2100	2030	1860	1750

In

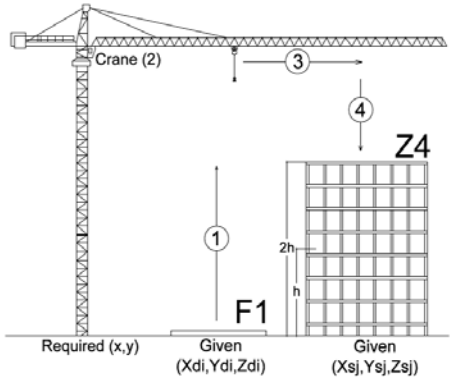

Figure 2 (a)- Transferring material using tower crane (elevation)

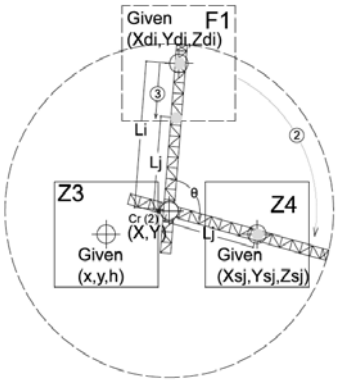

Figure 2 (b)- Transferring material using tower crane (plan)

tower cranes, there are 3 main types of movement. In Figure 2(a), the tower cranes is

going to pick up the load as a first step then it will rotate around its axis (see Figure 2 (b)), then the operator will move the cart forward or backward till the load is located on top of the desired location (see Figure 2 (a)), and finally he will put down the load (see Figure 2(a)).

As the construction area is fixed, the optimization focuses on the site facilities such as the fabrication yard, batch plant and tower cranes. Many constraints should be considered as follows:

- The distance between the working zone D_j and the facility zone D_i should be less than the crane jib (l_{cr}) or the lifting capacity radius.

$$\text{Max } (D_j, D_i) \leq l_{cr}$$

- Lifting capacity radius should be respected
- No overlapping between any two facilities
- The tower crane operator is not able to make two types of movements at the same time

Input data would be the coordinates of each zone and facilities' center, quantities to be transferred from place to another, the average height of each zone, crane slewing velocity and trolley radial velocity, and length of the crane jip (see Figure 3)

The output will be the optimum Cartesian coordinates of the center of each tower crane that gives the minimum travel time of all tower cranes.

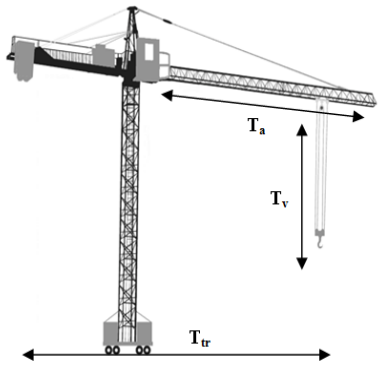

Figure 3- Trolley Radial movement, Vertical movement, and travelling movement

Calculating the hook travel time of cranes

This model is based on calculating the crane hook travel time. To calculate the number of cycles in a task, we need to know total task quantity and the weight that can be handled in one cycle.

No. of crane cycles = Total Quantity (see Table 3) / Max. Handling load (see Table 2)

With the objective of this paper is to determine the location of the tower cranes that would result in minimizing the travel time, the travel time is calculated using simple equations that link the distance, velocity, and time in the horizontal and

vertical plans. The distances can be calculated based on any suggested location for the crane (variable to be determined) and the fixed locations of both zones and facilities. The reader is referenced to figure 2 and Alkriz and Mangin 2005 for basic equations. Firstly, the horizontal travel time should be calculated (Eq. 1 to 4 – Alkriz and Mangin 2005). The horizontal travel time is depending on the hook travel time and the tangential travel time. Once the tower crane operator decides to pick up a load, he has to make two types of movement as a horizontal movement. The first move is trolley radial movement (T_a) (see Figure 3).

– – 1

– – 2

.... 3

..... 4

X, Y: coordinates of the centroid of crane; X_{di}, Y_{di}: coordinates of the centroid of building zone i; X_{sj}, Y_{sj}: coordinates of the centroid of facility j; T_a: time for trolley radial movement; V_a: radial velocity of trolley (m/min).

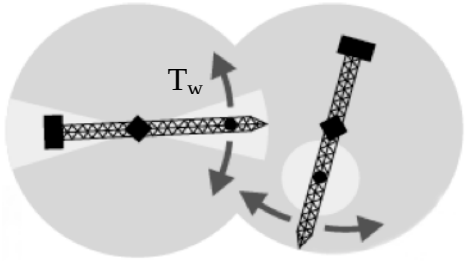

Figure 4- Trolley tangent movement

The second move is trolley tangent movement (T_w) (see Figure 4) (Alkriz and Mangin 2005)

T_w = – ….5

T_w: time for trolley tangent movement; W: slewing velocity of crane jib (r/min).

To calculate the horizontal travel time between any two points i, j (T_{hij}). The equation contains a coefficient (α) referring to the operator skill. This coefficient is placed in the equation because the operator should slow down while targeting the load either on the trolley tangent movement or on the radial tangent movement, and the velocity of targeting the goal depending on his skill and could be calculated using the following equation (Alkriz and Mangin 2005).

$$T_{hij} = \text{Max}\,(T_a, T_w) + \alpha.\ \text{Min}\,(T_a, T_w) \ldots. \quad 6$$

Secondly, the vertical travel time should be calculated. The vertical movement means the travel time of the hook vertically and could be calculated using the following equation (Alkriz and Mangin 2005):

$$T_{vij} = |Z_{di} - Z_{sj}| / V_v \ldots. \quad 7$$

V_v: vertical hoisting velocity of hook (m/min); $(Z_{di}–Z_{sj})$: vertical distance between the unloading point di and the loading point sj

The total travel time between any two facilities equals the horizontal travel time and vertical travel time. A coordination coefficient (β) is used to represent the coordination between the horizontal and the vertical movements. This coefficient is used because the operator will face more challenges to target the desired load, and the velocity of targeting the load is depending on his skill and his ability to coordinate between the two types of movements (Alkriz and Mangin 2005).

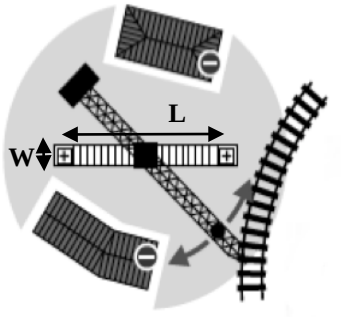

Figure 5 -Travelling tower cranes

$$\text{Total travel time } (T_{ij}) = \text{Max } (T_{hij}, T_{vij}) + \beta . \text{ Min } (T_{hij}, T_{vij})$$

Assigning the travelling tower cranes on the model

The model is going to deal with the travelling tower crane as a fixed building with two dimension (length, width) (see Figure 5) where the width of this building is the spacing between the rails of the tower crane which vary from 5.5 – 6.5 meters depending on the design of the tower crane. On the other hand, the length of the building is considered as a variable and needs to be minimized. The length will be calculated as the distance between two optimized positions for two tower cranes with no obstacles between the two points.

Checks

Coverage check should be applied for every crane by calculating the distance between the facility and the tower crane, then comparing the distance with the tower crane jip. If the distance is more than the tower crane jip, this facility is not covered with this tower crane. The coverage step should be applied on each tower crane (see Table 2), and then total check coverage should be applied to make sure that every facility is covered with at least one tower crane (see Table 3) where (0) means that the facility is covered with the desired tower crane and (1) means that the facility is not covered with this tower crane.

Table 3- Covering check on all tower cranes

	Check Crane (1)	Check Crane (2)	Check Crane (3)	Check all

Z9	54	14	55.79	31.25	1
Z10	60	10	60.83	31.25	1

Finally, there is another check that should be applied before running the model. This final check is the check of interference between tower cranes (see Table 4). In tower cranes positioning, tower cranes circles should be intersected to allow the operators to handle loads (see Figure 4). For example, in Figure 4, it is highly recommended to place crane (3) where its reach (circle) intersects with crane (1) reach. However, the intersection should be limited to prevent the first crane jip from hitting the mast of others (see Figure 5).

Table 4- Check of interference

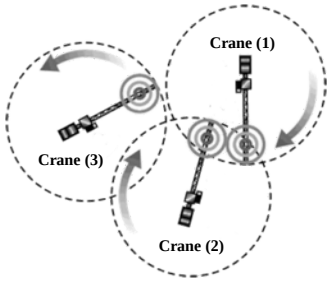

Figure 4- Interference example

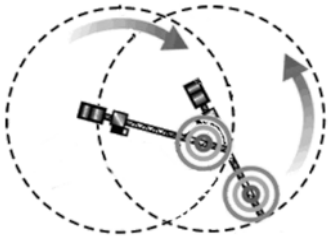

Figure 5- Interference error

CONCLUSION

Due to the rapid development of technology and complexity of construction projects, planning construction site layout became very challenging. Usually, effective site layout leads to cost reduction, duration reduction, and profitability increase. Therefore engineers always search for models for optimum construction site layout. The matter became very complicated if construction site contains tower cranes. This research introduced a Genetic Algorithm (GA) approach to develop a tower crane optimization model. The objective function of the GA model is to achieve the minimum crane travel time between project facilities. The output of the model is the number of tower cranes needed and the proposed position of each tower crane. The model takes also into consideration the case of travelling tower crane where the engineer can minimize the cost by using only one tower crane instead of two. This would happen by using one travelling tower crane on rails where the crane has the ability to move from one place to the other.

Acquirer's Protection vs Demolition of Illegal Buildings

Spain

Email: celia@der.uva.es

Abstract:
In the last decades, Spanish landscape has suffered a deep transformation. Buildings have appeared here and there, especially near the sea, and frequently without respecting urban law. In order to end with such situation, courts started to condemn liable persons to demolish buildings without permit or with an illegal permit. The main problem, which focuses the attention of this paper, is the second one: buildings with illegal permit. These ones are registered in the Land Registry, where it is shown that the construction permit was obtained. They seem to be legal and citizens acquire them trusting in this information. But years later they see how their apartments are demolished because that permit was illegal, and indemnity is not guarantied for them. They lose their property and the price. How can they be protected? Different interests – public and private- concur on these cases, and an adequate solution must be found. The purpose of this paper is focused on two questions: 1) analysing this serious problem and judicial decisions in this matter, and 2) according to the result of this analysis, proposing a way to resolve or mitigate the consequences of demolition, so security in real estate transactions can be restored..

Keywords:
Property, urban law, illegal permit, bona fides acquirer, Land Registry.

1 Introduction

One of the main problems in Spain, as far as construction is concerned, is the respect of Urban Law. When a building is contrary to Urban Law rules, we say that it is illegal. However, causes and conditions of the illegality are not always the same. In fact, circumstances related to the illegality can be very different from one case to another. Sometimes, the developer did not apply for the building permit and the lack of permit makes the building illegal. But in other cases the permit has been obtained and it is disclosed through the Land Registry, although it is an illegal permit because it was issued in spite of the Urban Law prohibitions. And in this case, bona fide acquirers buy the property trusting in the information provided through the Registry, which contains the building permit. Apparently, in this case the acquirer is acting according to law, and he ignores that the building is illegal.

However, even though there is a bona fide acquirer, the court will order the demolition of the building if urban law is considered not to be respected. The bona fide acquirer

 ISBN: 978-1-84219-840-7 .

suffers the consequences of the illegality. He was not responsible of the illegal permit and trusted in the legal information provided through the Land Registry. Nevertheless, his house or apartment will be demolished. And according to Spanish law, it will be very difficult for him to obtain an indemnity for the lost of his property.

There is a conflict between public and private law, between urban law and property law. Public interests related to the conditions of the buildings and private interests of acquirers are contradictory. And this problem must be resolved taking into account all the private and public elements concerned in this matter. Security in land transactions and respect to urban law are affected by this conflict and a satisfactory solution must be found.

Along this paper I will explain the problem from both public and private points of view. And I will try to offer a proposal in order to approach two positions which seem to be impossible to conciliate.

2 Illegal Permits and the solution from Urban Law

Unfortunately, the Spanish landscape sometimes consists of buildings contrary to urban law prescriptions. In some cases the illegality is due to the absence of the building permit –it happens very often in the countryside-. In other cases the construction is carried out with all the legal formalities and the building permit is obtained, but this permit is illegal. Why?

In a reduced number of cases, there is a mistake of the municipality, so the permit is provided contrary to Law but without realizing of it. More frequently, corruption and kickbacks are in the root of the problem –in fact, some politicians have been condemned or are being judged for these crimes-. The developer is interested in constructing a building which is prohibited by urban law. But such a building will allow him to make a lot of money –i.e., a building with a number of floors over the maximum established by urban law prescriptions-. In order to obtain the building permit, the developer offers some benefits –usually economical benefits- to the responsible person at the municipality, so the illegal permit is issued. Then, the construction is carried out with a building permit and it seems to be legal because all the formalities have been accomplished. But actually it is illegal, and both the developer and local authorities know it.

Such behaviours have been produced frequently in certain areas of Spain where economical interests and investment play an important role, i.e. next to the sea. And during the housing bubble it gave rise to a complete transformation of the landscape: buildings have appeared everywhere, without control, and in an unmeasured way.

As a reaction against this situation, almost systematic in some cases, courts started to order the demolition of illegal constructions. Demolition is synonymous of destruction of wealth, so it never used to take place in Spain in cases of breach of urban law. It was preferable to establish another consequence in case of illegal buildings, i.e. an economical compensation. Nevertheless, under current circumstances illegal permits are so usual that courts and some authors (Rodríguez-Fernández, 2009; Cabello-Martínez and García-Sanz, 2010) consider demolition as the only way to restore legality. There

are many judicial decisions ordering the demolition, for instance, the sentence of the Spanish Supreme Court of July 9th, 2007 (La Ley 79397/2007), which contains all the legal arguments to order the demolition –basically the need to restore legality- and refers to several sentences resolving in the same way.

The problem is that demolition is ordered in any case of breach of urban law, without taking into account the circumstances of each case. As explained above, the illegality can be the result of a mistake or a conscious action. And in any of both cases, the current owner of the building could have nothing to do with the breach of law. The developer may have sold the house to a bona fide purchaser who spent all his savings in this acquisition, subscribed a mortgage loan and established his home in the building which has to be demolished. Nevertheless, the court does not make any distinctions and orders the demolition regardless the owner's attitude. The situation is even worse for the acquirer when he has to repay the loan to the bank even after the demolition of the building.

Consequently, demolition seems to be unfair in case of a bona fide purchaser who did not suspect at the time of closing the contract that the building was contrary to urban law (Revueta-Pérez and Narbón-Laínez, 2010). Everything looked legal because there was a building permit and the house was registered in the Land Registry. But this bona fide purchaser will have to suffer the consequences of the illegality: the demolition. Let us examine the situation of this acquirer and his protection according to Spanish Law.

3 Bona fide purchasers: protection or punishment in Spanish Law?

If the construction is carried out without a building permit, registration cannot take place in the Spanish Land Registry. One of the prerequisites for registering the building is the permit, so if it has not been issued, registration will be refused by the registrar. The absence of registration reveals the lack of the building permit, and the acquirer can easily realize of the irregularity and he can suspect that there is a breach of law. In this case, if the court orders the demolition, the purchaser will suffer the consequences of the illegality even though he did not take part in the construction. His decision of buying the house was risky and he knew it. Since he decided to buy a non-registered house, he entered into an illegal relationship and now he has to bear the consequences. These are the arguments held by the Supreme Court in the decision of February 6th, 2007 (La Ley 1589/2007).

Nevertheless, in case of a registered building -and registration of the building permit- the behaviour of the purchaser is completely different and Law should be different too. But according to the current judicial decisions, such purchaser suffers the same consequences than in the case described above and he loses his property. Besides, if there was a mortgage loan, the mortgage disappears with the destruction of the mortgaged object –the demolition of the building-, but the loan persists and the acquirer has to face the repayment. The situation is especially dramatic when the house is the home of a bona fide purchaser who loses it with the demolition.

The consequences of the breach of urban law are not distributed in a right way. Authorities of the municipality and the developer have caused the breach of law, but

they are not punished for their behaviour. The demolition is suffered by the current owner and partially by the community because the expenses of the demolition are paid by the municipality with public funds. There are not any consequences for the authorities and the developers who were conscious of their acts and provoked the breach of law with the illegal permit.

The problem has reached an international dimension: it is quite common that European Citizens buy a house in the cost of Spain, where urban development has been extraordinarily excessive in the last years and illegal permits are usual. They follow all the steps to acquire a house according to Spanish Law and, like Spanish acquirers, lose their property with the demolition and without indemnity. The problem is the same for both, Spanish and other European Citizens. But as far as people from other countries are involved, several claims have been made at the European institutions and hard critics to the Spanish real estate transactions and legal security have been issued. A clear example is the Auken Report of the European Parliament. This report pays attention to the irregularities of the Spanish municipalities as far as urban law is concerned and the deficiencies of the Spanish legislation, and denounces the infringement of ownership right when demolition is ordered. Besides, the report claims liability of the authorities who allow behaviours related to illegal buildings. The result –concludes the report- is the mistrust in the Spanish legal system and in real estate transactions: bona fide purchasers are not protected because they lose their properties without indemnity.

Let us explore now whether the legal protection of bona fides acquirers could be improved in the cases of illegal permits. First, we will analyze the solutions offered by the courts in order to conclude if they are satisfactory or not. Then, we will examine the problem from the perspective of Land Registry Law. It is important to bear in mind that the illegal permit is disclosed through the Registry as a legal one and that registration has very strong effects in Spanish Law.

3.1 Protection Suggested by Courts

Owners of illegal buildings have sued to avoid the demolition, especially when they were bona fide purchasers. Nevertheless, courts are very strict in this matter and hold that the only way to restore legality is by pulling down the building. Obstacles to demolition alleged by owners are refused by courts: modifications of the urban planning, proportionality between the illegality and the sanction, legal or physical impossibility to accomplish the sentence, and conclusive title of the current owner. Some examples are the decisions of the Supreme Court of April 29th, 2009 (La Ley 58399/2009) and July 9th, 2007 (La Ley 79397/2007). And it is considered that bona fide purchasers can obtain the protection of their legal interests through other ways. That was stated in the sentences of the Supreme Court of May 12th, 2006 (La Ley 57549/2006), September 26th, 2006 (La Ley 119633/2006), February 6th, 2007 (La Ley 1589/2007), February 4th, 2009 (La Ley 14506/2009), and December 29th, 2010 (La Ley 217776/2010).

From courts' point of view, remedies should be found in contract law and in tort law. Let us see now these remedies and their obstacles.

3.1.1 Contract Law

If the object of the contract –the house or the apartment- is illegal, the contract is void. However, instead of recognizing it, courts hold that there is a breach of contract and the purchaser should claim in order to obtain the restitution of the object and the price, and a compensation for damages.

But the success of such a claim is not easy for several reasons (Revueta-Pérez and Narbón-Laínez, 2010). First, it is required that the purchaser has an evidence of the seller's fault. It means that the seller knows the illegality of the permit at the time of the sale. When the seller is the developer, it is quite possible that he was conscious of the real circumstances of the permit; however it is very difficult to prove it. And if the seller is a former acquirer, he probably had nothing to do with the illegal permit and was conscious of it. Second, even if the acquirer was able to prove the seller's fault, the restitution of the building would not be possible because of the demolition. And third, in most of the cases the restitution of the price would not be effective for practical reasons: the developer is usually a company with limited liability and has not enough assets to pay, or in other cases the company has disappear as a consequence of the current economical crisis. Under these circumstances, a compensation for damages will find the same practical obstacles.

Shortly, from a theoretical point of view the restitution of the price and the object of the contract could be a possible solution. Nevertheless, the practice demonstrates that it is not the way to provide adequate protection to bona fides purchasers.

3.1.2 Tort Law

As said before, in some cases there is not a contractual bind between the persons who dealt with the illegal permit and the purchaser. That is the case of the purchaser of a former purchaser. Then, contract law cannot provide the solution, and tort law could be, perhaps, the tool that we are looking for in order to protect the current owner of the building.

However, also in this case it is very difficult to prove that the developer knew the illegality. And fault is a prerequisite for compensation, so the claim could hardly have success. Besides, in this case there are the same practical problems to obtain an effective compensation due to the limited assets of the company and the risk of disappearing for bankruptcy.

Both contract law and tort law are unable to satisfy bona fides purchaser's interests. But the developer is not the only one who can be responsible of the illegality. The municipality issued the illegal permit and could be also liable for such behaviour (Rico-Ruíz and Casado, 2007).

3.1.3 The liability of the municipality

The municipality issued a building permit contrary to urban law. This illegal permit produced the appearance that the building was under the prescriptions of Law. And a bona fide purchaser acquired it in the belief that there were not any legal obstacles to his ownership right.

 ISBN: 978-1-84219-840-7 .

But later a court holds that the building permit is illegal and that the building has to be demolished, with the subsequent prejudices to the current owner of the house. So this owner can sue the municipality for issuing an illegal permit. From a practical point of view, the problem is that condemnation of the municipality means that the indemnity would have to be paid with public funds. So all citizens would have to support this liability with their taxes, which does not seem to be fair.

Besides, in practice it would be very difficult to make the effective payment of the compensation because currently, and due to economical crisis, Spanish municipalities have very limited funds.

Consequently, nor a claim against the developer, nor a claim against the municipality would have success in practice, and the current owner of the demolished building could not obtain a compensation for damages. However, in Spanish Law there are other rules that could provide protection: property law and especially the regulation of the Land Registry. But courts are reluctant to recognize the effectiveness of these rules in these cases. Let us see now how the protection through the Land Registry could be provided and its obstacles.

3.2 Protection through Land Registry Law: Why not?

In Spain there is a title registration system. However registration is not required to become the holder –except in case of mortgage-. But those who register their rights obtain special protection in spite of non-registered rights. And if certain prerequisites are accomplished, the holder with a registered right will have conclusive title.

When the owner is a bona fide purchaser, and the court orders the demolition because the building permit is illegal, it is usual that this owner claims the protection provided in article 34 LH (Ley Hipotecaria, the Spanish Land Registry Law). According to this article, the person who acquires a property right through an onerous contract, in bona fide, from a person who is registered as the owner, and registers the acquisition, becomes the real owner even if the transferor's right is voided or resolved.

From these purchasers' point of view, the illegal permit is a case of conclusive title (Guilarte-Gutiérrez, 2011). Let us see their arguments.

The Land Registry discloses the legal situation of the property. There is a legal presumption: what is published is right and there are not any mistakes, the right exists in the disclosed terms and it belongs to the registered holder (article 38 LH). This is a disputable presumption, so anybody can prove that one registration is wrong. However, in the meantime the presumption produces some legal effects. And it is also the basis to recognize cases of conclusive title. Anyone who trusts in the rights disclosed through the Land Registry and acquires the right with the prerequisites of article 34 LH is protected by Law. He has an indefeasible title. It can occur even in really serious cases, for instance, when the seller obtained the property through a criminal behaviour. If the acquirer is in the situation described in article 34 LH, his title will be indefeasible (Revueta-Pérez and Narbón-Laínez, 2010).

 ISBN: 978-1-84219-840-7 .

According to these ideas, the purchaser of a house or an apartment with an illegal permit is acquiring a void title. The title is void because the object of the right is contrary to the law, is contrary to the prescriptions of urban law. But it seems to be legal because of the disclosure provided through the Land Registry and the presumption of article 38 LH. Part of the legal information provided through the Land Registry is related to urban law. The RD 1093/1997 set up that some matters related to urban law must be registered. Spanish Land Registry discloses the title, but also the building permit. In fact, the ownership right cannot be registered if the applicant does not submit the building permit. So it appears that everything is according to the law. And under these circumstances the purchaser acquires the right, trusting in the information disclosed through the Land Registry. Therefore, if a court holds that the building permit is contrary to Law, it means that the ownership right of the transferor is void because the object of the right –the house or the apartment- is illegal. But if the transferee is a bona fide purchaser with the prerequisites of article 34, he should have an indefeasible title and should have to be protected from demolition.

If the Land Registry would not take into account the building permit, the legal problems related to it could not be under Land Registry law. But as far as the building permit and other circumstances related to urban law are disclosed through the Land Registry, and they are included in the registration of the ownership right, all these circumstances should have to be protected. Otherwise, security in real estate transactions would not be properly provided through the Land Registry (Revueta-Pérez and Narbón-Laínez, 2010). Acquirers could not trust in the legal information disclosed because it could be wrong, and in that case the purchaser would suffer the consequences. Although apparently everything is right, it could not be guaranteed.

In short, the ownership right of the apartment is contrary to law because the building permit is illegal. The ownership right is void. But if there is a bona fide purchaser, his right must be protected even if it is illegal. Security in real estate transactions must be provided so he should be considered to have an indefeasible title, and the building could not be demolished. That would be the consequence according to Land Registry law.

However, courts refuse these arguments. Article 34 LH is not considered as a way to protect the ownership right against an illegal permit. The rule is referred to the case of avoidance or revocation of the transferor's right. And it is completely different to the case of disappearance of the object as a consequence of the law. These are the arguments held by the Supreme Court in February 4th 2009 (La Ley 14506/2009), April 29th 2009 (La Ley 58399/2009), and December 29th, 2010 (La Ley 217776/2010).

This reasoning is not easy to understand. However, it is exactly what courts hold repeatedly in all their decisions related to this matter. It is quite difficult to notice the difference between the case in which the transferor's right is considered void by a court and the case of illegal building permit, which makes the building contrary to law. Courts hold that in the second case the ownership right can subsist without the building. But it is hard to imagine the right of an apartment's owner when the building is demolished (Guilarte-Gutiérrez, 2011).

 ISBN: 978-1-84219-840-7 .

Then, why is there a refusal to protect bona fide purchasers? Let us examine now all the interests concurring in these cases and the fears or threats that probably are in the basis of these judicial decisions.

4 The conflict: Urban Law vs. Land Registry Rules

According to urban law, in case of illegal permit the building should be demolished because this is the only way to restore legality. Nevertheless, Land Registry rules set up that the bona fide purchaser must be respected in his acquisition if the prerequisites of article 34 LH are accomplished, even if the right of the transferor is void.

It is clear that in case of a bona fide purchaser, there is a contradiction between urban law and property law. But courts hold that article 34 is not referred to these situations and the solution is demolition. Actually, courts hold that in case of conflict between urban law and property law, the rules of urban law are preferred.

Nevertheless, in some cases there is a breach of urban law but the building is not demolished. Then, the legality is not restored. These cases are exceptions to the general rule. For instance, when the time to sue has expired, courts hold that the illegal building must be respected in spite of the breach of Law (Villanueva-López, 2010). However, article 34 LH is not considered as an obstacle for demolition, even though the Spanish system of security in real estate transactions is in danger with such a decision. Why?

There are some circumstances that could explain, perhaps, the position adopted by courts in this matter. Certainly, article 34 LH is the rule to provide security in real estate transactions. But its application must be extraordinarily unusual because it triggers serious consequences. At the end, article 34 means that an illegality, whatever it is, must be allowed in order to protect a bona fide purchaser. Therefore, this article can operate only in contexts where the level of legal security is high, which involves that effects of article 34 will take place in very few cases. Only in these few cases the illegality could be accepted by Law in order to protect the bona fide purchaser's interests.

According to this argumentation, we have to analyze whether building permits are being issued in Spain in satisfactory terms, as far as legal security is concerned. And we cannot conclude that building permits are mostly legal in Spain (Villanueva-López, 2010). Far than this, procedures to issue building permits do not contain enough control. However, building permits are considered to be legal until a court set up the opposite. And even in case of claim against a building permit, the existence of the trial used not to be disclosed through the Land Registry. So the appearance of legality persisted and the purchaser could not suspect that he was assuming a risk with the transaction because there was not any evidence of it in the Land Registry books.

Under these circumstances, recognizing the protection of article 34 to the bona fide purchaser would trigger the inefficacity of urban law: demolition would not take place and urban legality would not be restored. The building permit would be contrary to Law, and the illegality would persist to protect the bona fide purchaser. And this kind of situations could be relatively usual, so nor an important number of illegal buildings could be demolished, nor urban legality would be restored.

 ISBN: 978-1-84219-840-7 .

However, in 2011 there was an amendment of law (Real Decreto-ley 8/2011), so now every claim against a building permit must be recorded in the Land Registry. Such a rule has a clear purpose: every person interested in acquiring a house or an apartment will check the legal situation of the property in the Land Registry. And if there is a trial related to the legality of the building permit, this person will have notice of it. The amendment improves the legal information of the Land Registry, and in case of acquiring the property in spite of the claim, the transferee will not be able to be considered as a bona fide purchaser. Therefore, article 34 LH is excluded.

This amendment is a first step in order to increase security in real estate transactions. If procedures carried out at the municipality were improved too, cases of illegal permits would be reduced, and the landscape of urban law would suffer a deep transformation. In that case, it may not be obstacles to recognize the consequences of art. 34 LH when a bona fide purchaser of a house or an apartment realizes that the building permit is illegal. The application of the rule would be so unusual that the efficacy of Urban Law would not be in danger. Then, the demolition would be replaced for another measure, and liable persons –developer and/or authorities of the municipality- would have to face the consequences of their behaviour.

However, in some cases urban law protects interests with special value, i.e., environment, historic and artistic heritage. It is hard to understand that in these cases the bona fide purchaser should be protected in spite of Urban Law. From my point of view, these cases should be an exception to the general rule, so demolition should take place then to restore legality.

5 Conclusion

Urban Law and Property Law establish contradictory rules for the bona fide purchaser who acquires a house or an apartment with an illegal permit. Until recent dates, courts held that demolition should be the reaction against this breach of Urban Law because that is the only way to restore legality. However, this solution does not provide security in land transactions.

The purchaser must be able to know if there is a trial related to the building permit. New rules order to disclose this trial in the Land Registry books. It would be also desirable that cases of illegal permits would be reduced by introducing controls at the municipality. Under these circumstances, cases of bona fide purchasers would be so exceptional, that article 34 LH could be preferred over urban law because its application would be reduced to exceptional cases. Article 34 LH would not be a threat to the efficacy of Urban Law. Nevertheless, in any case where the permit is contrary to rules protecting environment or historic and artistic heritage, the priority of article 34 LH should have to be refused.

Abstract:

The climate change causes challenges for the distribution of electricity in Finland and countries with similar weather conditions. The power lines are in Finland situated above the ground and when heavy heaps of wet snow gather on the tree branches, the branches will break under the snow's weight. This often results in the branches to collapse on the power lines causing power shortages that may in worst cases take for days to repair. The problem is of significance especially in the scattered settlements. This has led to a vivid public discussion that the energy companies should take the initiative to lay the old airlines underground and it can be argued that there is a significant public need for such a move. However the legislation concerning the power grids, their placement and the expropriation of private land is at the moment old, ambiguous and non-uniform creating challenges for the process. The outcome of the process is usually not problematic for the parties of the process however its slowness often causes unnecessary harm for both the landowner whose land is expropriated and the company carrying out the power line initiative. Since as little harm as possible should be caused to the land owner when the power lines are located on private property, it can be also argued that it usually causes less harm for the land owner if the power lines are located as underground cables instead of locating them as airlines. Therefore uniform legislation would be needed in order to make the process more efficient.

Climate change, Finland, expropriation, power grid, public needs

1 Introduction

In recent years there has been a growing interest towards climate change. Current research data implies that climate change causes winters to be milder and windier than they previously were.[1]

This will probably show as yearly increases in the annual snowfall, which causes challenges for the undisturbed distribution of electricity. The power lines in Finland are situated above the ground and when heavy heaps of wet snow gathers on tree branches,

[1] VNS 8/2009 vp, p. 117.

 ISBN: 978-1-84219-840-7 .

the branches will break under the snow's weight. This often results in the branches collapsing on the power lines causing power shortages that may in worst cases, take days to repair. This is a significant problem especially in the rural areas.

This has led to a vivid public discussion that energy companies should take the initiative to lay the old airlines underground. It is arguable that there are significant public needs for such a move. It is generally accepted that in the long term, the total expenses are smaller if the lines are laid underground than constantly fixing the airlines and paying compensation to those who suffer from power shortages.

For the time being, energy can only be transferred through power lines. For this purpose both, airlines and underground cables are used. In most parts of Finland, the power lines are still located above the ground as airlines. However, the lines are not located over the tree lines as is done in some countries with similar weather conditions.

Both systems, underground cables and air lines, have their pros and cons. While airlines are cheaper, easier to locate and to fix, they are vulnerable to weather conditions and they often have a negative aesthetic effect on the landscape. They can also cause danger to people and machinery: for example when fixing an airline the repairman may get injured when climbing to the pylon or agricultural machinery may hit the power lines.

The underground cables usually require less space and hence cause less harm to the land owner who has to submit to the limitations of land-use if the power lines need to be located on his / her land. They are also better secured from the weather conditions such as wind and snow. Furthermore, they are better approved by the public, because they are the less visible. However they are much more expensive than the airlines, more difficult to fix and subject to technical problems. Furthermore, it is very difficult to dig the lines into soil which has high stone concentration and nearly impossible where the bedrock is close to the surface.

The legislation concerning power grids, their placement and the expropriation of private land is at the moment ambiguous and non-uniform. This creates challenges for the process which tends to be slow and bureaucratic. An average power line initiative can take up to eight years with all its phases and this can result in significant harm for all the parties involved including private land owners and energy companies.

Most of the legislation concerning power grid initiatives is very old. As infrastructure and society has changed after these Acts have come into effect they do not adequately meet present day needs. For example the Land Use and Building Act (132/1999, LUBA) was effectively copied from its predecessor Building Act (370/1958) this Act had already come into effect in 1958. Since then, the need for electricity has grown substantially and various applications of electricity usage have increased. The decentralized production - which is needed in promoting renewables-based electricity production, e.g. wind farms and smaller scale biomass power plants - also brings along its challenges, creating a growing need for new power lines.

Previous research has not been done in this field in Finland. None of the Finnish ministries possess a complete Guide of the regulatory package on expropriation and permit system concerning the power grid initiatives. Therefore the purpose of this paper

is to examine the permit system and expropriation legislation concerning the power grid initiatives and to point out the possible minefields in this area.

2 The Finnish Power Grid and Permit System

Finland has a free energy market. The Finnish grid is owned and administered by two different bodies: The Finnish national grid is administered and operated by Fingrid Ltd. (comprises of 400-, 220- and the most important 110 kV power lines). The end user distribution, i.e. regional and local grid, is administered by the regional and local electricity companies. The regional grid comprises mostly of the 110 kV lines. The local grid comprises mostly of 20 kV power lines and 400 v lines.

For the 220 and 400 kV power grid initiatives an environmental impact assessment procedure (EIA) based on the Act and Decree on Environmental Impact Assessment Procedure (Act 468/1994, Decree 713/2006) is required when the power line exceeds 15 km in length. If the initiative concerns power lines with less than 220 kV, Centre for Economic Development, Transport and the Environment can decide whether or not EIA is needed for minor lines.

According to Energy Market Act (385/1995) if the power line is at least 110 kV, a planning permission from the Energy Market Supervising Authority is required. This permission does not yet retain the expropriation permit, and it needs to be applied separately from Council of State. The expropriation permit is granted in accordance with the provisions of Expropriation Act (603/1977, ExpA).

If the power line is less than 110 kV, the expropriation permit can be applied in accordance with the provisions of LUBA. The last part of the power line serving a real estate can be expropriated in accordance with the provisions of Real Estate Formation Act (554/1995, REFA) or ExpA, but it is usually done according to LUBA.

If the airline is at least 220 kV and exceeds 15 km in length the Act on the Right to Expropriate Concerning Certain Initiatives Having an Impact on the Environment (768/2004) gives certain organizations, such as environment protection organizations, right to appeal the permit if they are operating in the area where the initiative is carried out. It is to be noted that the right to appeal applies only to air lines and not the underground cables.

If the power line is located in the water, (for example to pass under the sea, a lake or a river) the right to use privately-owned water bed is established in accordance with the provisions of Water Act (584/2011). In this article the problems concerning location in the waters will not, however, be discussed.

3 Legislation on Expropriation in Power Grid Initiatives

3.1 Conditions of Expropriation

Private ownership in Finland is protected by section 15 of the Finnish Constitution (731/1999). This right may be restricted only by legislation and on condition that there are public needs for it and that full compensation is paid to the owner. Especially the

land owners often need to submit to the limitations of land use for public needs. Public needs are an essential prerequisite for expropriation. Where the public needs requirement is not fulfilled, expropriation is possible only where the procedural requirements for constitutional legislation are met.[2]

In addition, there are certain other principles for expropriation of private land; first, it is very important to notice that the expropriation should always be the *ultima ratio* for land acquisition. In other words, expropriation should only be used if the acquisition has not been possible in any other way. Also, the land owner should suffer as little harm as possible.[3]

Second, the land owner should always be granted full compensation when the land is expropriated. This means that the land owner's financial situation should remain the same despite the expropriation.[4] Even though the principle may seem simple, there are certain problems in it. These problems will not be discussed in this article.

Since permit for expropriation is always required, the existence of a right to expropriate is always at the discretion of the authority. The type of the initiative determines which authority grants the permit for expropriation in the power grid initiatives.

More often than not, the land is not expropriated within the power grid initiatives; instead, a right to use the private land is given to the company carrying out the initiative so that the land owner will remain in ownership of the land after a voluntary agreement is made on the land use, or coercive measures are taken. The land owner will still be able to use the land, but limitations to the land use are usually inevitable. The land owner will be compensated for the harm and damage.[5] The basis for the compensation is laid down in ExpA. The compensation is only paid for economic losses. Hence, sentimental value, for instance, is not compensated.[6]

3.2 The Regulatory System of Expropriation in Power Grid Initiatives

Conditions of expropriation can be divided into two categories: general and special.

The Expropriation Act provides the general legislative framework for expropriation in Finland. The general condition for expropriation is defined in ExpA section 4. According to it, expropriation is possible if required for public needs, but notwithstanding this, expropriation shall not be used if the inconvenience to the private outweighs the public benefit. Public needs are defined as being something more than a public benefit. This is because public benefit may be caused by actions that are not downright required by the public needs.[7]

The provision does not provide an exhaustive list of the circumstances when the public needs exist, nor is there an unambiguous interpretation for the concept. This kind of a

[2] Hyvönen, 1993, p. 31.

[5] Ekroos and Majamaa 2005, p. 726.
[6] Ojanen, 1976, p. 114.
[7] Kuusiniemi and Peltomaa, 2000, p. 109.

list has not been considered practical, since the circumstances, legal praxis and political views change through times.[8]

Furthermore, according to section 4 of the ExpA, expropriation shall not be carried out if the objective of the expropriation can be achieved by some other means. Usually this means a voluntary agreement with the land owner. This should however not be interpreted so that the energy company carrying out the initiative should always primarily aim to conclude a voluntary agreement with the land owner. On the contrary, it is usually justifiable to carry out the expropriation according to ExpA if the energy company needs to acquire rights to several smaller land areas, as the case usually is in the larger scale power grid initiatives.[9] Despite this point of view, Fingrid for example always tries to negotiate with the land owners before the expropriation process is started.[10]

Carrying out the process according to ExpA has its definite redeeming features, because the principle of equality, secured in the Finnish Constitution, section 6, will be realized between the land owners. It is often also faster to carry out the process according to ExpA instead of negotiating a voluntary agreement with all the landowners separately. If the process is carried out in accordance with ExpA the easements / rights established in the private properties are also appropriately registered. This means that if the owner of the property later changes, the easements will legally bind the successor as well.[11]

ExpA is applied if there is no special legislation concerned. Special conditions for expropriation are defined in several Acts and the conditions are always defined exhaustively.[12] In the power grid initiatives expropriation proceedings can *always* be carried out in accordance with the provisions of ExpA if there are public needs for the power grid. Other relevant Acts concerning expropriation in power grid initiatives are LUBA, Power plant Expropriation Act (168/1928) and REFA.

The Land Use and Building Act has provisions concerning the location of service conduits serving the community such as power lines. According LUBA, section 161 property owners and titleholders are obliged to allow the location of service conduits serving the community or the property in the area they own or hold the title to, unless the location can be organized satisfactorily by some other means and at reasonable cost. Service conduits may not be built so that planning of the area or implementation of a plan is hindered. Unless an agreement is reached with the property owner, the decision concerning the location is made by the local building supervision authority. Causing undue harm to the property shall be avoided when the location is decided upon.

According to section 161, paragraph 3 of LUBA, the owner or titleholder of a property is entitled to be paid compensation for harm and damage caused by the location of service conduits. Unless an agreement is reached on compensation, the matter shall be resolved as laid down in ExpA. Thus, the local building supervision authority only makes the decision concerning the location of the service conduits and does not decide on the compensation to be paid for the land owner.

[8] Ojanen, 1976, p. 42. ; Hollo, 1984, s. 156.
[9] Ojanen, 1976, p. 43.
[10] www.fingrid.fi.
[11] Ojanen 1976, p. 43.
[12] Yli-Laurila 1995, p. 9.

The section requires that the service conduits serve the community or property. In the legal praxis[13] it has been reviewed that the service conduit serving the community referred in the provision may concern a village in the area of the same municipality of the property, but not a service conduit serving the national grid or even the regional grid.[14] However, power lines serving a wind farm have not always been regarded as service conduits serving the community. Hence it is not always clear whether the service conduits serve the community or not. At least it is questionable whether a grid from a private wind farm to a local or regional grid serves that function.[15]

Primarily the location of service conduits serving the community or property, such as power lines, should be organized by some other means, but if this cannot be achieved satisfactorily and at reasonable cost, the land owner is obliged to allow the location on his / her land.

The primary means to carry out the process is hence to negotiate on the location and the compensation with the landowner and only if the parties do not reach an agreement the local building supervision authority will solve the matter. If the land is acquired by expropriation or an easement is established with coercive measures, the provision requires that the landowner should suffer as little harm as possible.[16] In this light it could be argued that least harm is caused to the land owner if the service conduits are located underground instead of locating them as airlines.

The Power plant Expropriation Act *(*PExpA) is a special Act concerning expropriation in power grid initiatives. According to PExpA a property owner can be obliged to give away the property or to submit to the restrictions of the land-use, if a power plant serves a *somewhat* public function. However the provision sets special conditions for the expropriation: It is forbidden to expropriate land from nearer than 100 meters from a building or garden, unless other area cannot be expropriated without a very significant inconvenience instead. The expropriation proceedings are carried out in accordance with the provisions of ExpA.

The Act has been enacted in accordance with the procedural requirements of constitutional legislation. This is because it allows the expropriation of real property for the purposes of a power plant serving only a *somewhat* public function. It has been considered that if the power plant serves a *public function* the public needs exist and the expropriation can be carried out in accordance with the provisions of ExpA. Thus the *somewhat* public function does not fulfill the requirements for public needs, but the public function may fulfill them.[17]

The Real Estate Formation Act*,* section 154 is a provision concerning restrictions to land-use. According to it, to benefit a real estate, a right as a permanent easement may be established in the area of another register unit to place and use the equipment and structures connected with telephone, electricity, gas, heating and other such cables and wiring. Similarly in LUBA, an easement based on an agreement between the landowner and the company carrying out the initiative is the primary method compared to the coercive measures.

[13] See for example Supreme Administrative Court's decision 1994 A 39.
[14] Ekroos and Majamaa, 2005, p. 725.
[15] See Supreme Administrative Court's precedent 1983 A II 109.
[16] Ekroos and Majamaa, 2005, p. 725.
[17] Ojanen, 1976, p..59 ; See also Hyvönen 1993, p. 127.

It is also noteworthy that according to this provision, an easement may only be established *to* benefit a real estate. In practice this means that only the last part of the power line can be located on the property in accordance with the provisions of REFA. This means that the whole power line going through several parcels of real estate cannot be located in accordance with these provisions.

LUBA and REFA are alternatives in the sense that in power grid initiatives concerning regional and local grids with power lines less than 110 kV (not the national grid which always requires a permit grated in accordance with ExpA) the easements may always be established in accordance with the provisions of LUBA. Since the conditions of establishing an easement in accordance with the provisions of REFA are not as broad as in LUBA, section 161, and the process is faster and more flexible in LUBA, the permit for the easement is usually applied in accordance with LUBA, section 161.[18] As mentioned earlier, the whole process can also always be carried out in accordance with the provisions of ExpA, although it is usually impractical, if the process can be carried out in accordance with the provisions of LUBA.

3.3 Public Needs or Somewhat Public Function?

In legal praxis the question whether the power plant serves a public function (public needs) or a somewhat public function has been figured in the Supreme administrative court's precedent 2007:41. In this decision, a power line was needed to serve an industrial plant. The plant had a significant importance for the economy of the area and also involved a local employer, and thus it could have been argued that it served the public benefit. However the Supreme administrative court held that as power lines in question served only the industrial plant and thus it only had a *somewhat* public function. Since the permit for the power line had earlier been granted in accordance with the provisions of ExpA, and no public needs could be identified, the permit should have been granted according to PexpA.

The decision indicates that the line between the public function and the somewhat public function is very open to interpretation. This adds confusion to the already ambiguous legislation.[19]

Travaux préparatoires on PexpA do not clarify the purpose of the Act.[20] PExpA was enacted at the time when the old Finnish Constitution (94/1919) and Finland as a state were barely 10 years old. The interpretation of the Constitution was at the time still much undeveloped. The government bill on PExpA merely states that the Act had to be enacted according to the procedure required for the enactment of constitutional legislation. The reason for this, however, was not explained. It is has been suggested that it was regarded unconstitutional because it infringed the constitutional protection of property rights.[21]

PExpA has been regarded unconstitutional after the enactment of the new Finnish Constitution.[22] Since it was enacted according to the order of procedure required for the enactment of constitutional legislation, it does not pose a legislative problem. However,

[18] Hyvönen, 2001, p. 558.
[19] See also Supreme administrative court's precedents 1982 A I 7-8 and on the contrary 1998:32 about the application of general and special conditions of expropriation.
[20] See Government Bill HE 38/1927 vp, p. 3.
[21] OM 2002:8, p. 16.
[22] OM 2002:8, p. 16.

 ISBN: 978-1-84219-840-7 .

if such a legislative initiative was tried to be set today, it would most likely not pass. Therefore it can be asked, should PexpA be struck down as unsuitable for modern society?

Since the energy companies are private players in the market it can also be questioned whether the public needs always really exist when expropriating in accordance with the provisions of LUBA and REFA. Thus it could be argued that they may actually be seen as somewhat unconstitutional as well, but in practice this has not yet been challenged. In most cases public needs can be indicated, but for example, it could be possible to argue that if an electricity company was building a power plant in Finland solely with a purpose to sell electricity abroad with an intent to make profit, it would perhaps be possible to argue that no public needs could be identified.

4 Conclusions

The expropriation process seems to be too slow and too bureaucratic creating unnecessary challenges for decision making. The slowness of the process often causes unnecessary inconvenience for both the land owner and the energy company. Since the legislation is also ambiguous it is not always clear which one of the relevant Acts should be applied in each case.

The obsolescence of the legislation is prone to making the process slow, because it is difficult to apply the legislation in the present day. The relevant provisions were enacted decades ago, when the societal framework was much different than today. One alternative to make the process work faster and more efficiently would be to enact new, uniform legislation for the expropriation and permit system in power grid initiatives.

The line between the public needs and the somewhat public function and hence which one, ExpA or PExpA, should be applied is not either anywhere near clear. The purpose of PExpA has not been clarified either and therefore it can be asked whether the Act should be struck down completely. Comprehensive legislative initiative will be taken concerning the power grid regulation, it should be considered whether there is any requirement for this outdated Act anymore.

Since all the measures should, when expropriating, be taken so that as little harm as possible is caused to the land owner, it can be argued that less harm is caused if the power lines are placed underground instead of placing them on the land owner's property as airlines. This could in fact be interpreted so that the new power lines should always be laid as underground cables, since this causes least harm to the land owner compared to the airlines. On the other hand it can be argued that it is sometimes for the public benefit to locate the lines above ground for economic reasons.

Environmental Law And The Restrictions On The Right To Use And Enjoy Property In Nigeria

Dr. (Mrs.) Beauty Oboraghware Alloh[1]

[1]Acting Head of Private & Property Law Department

Delta State University, Cleveland, MS 38733

United States

Email:boalloh@yahoo.com

Abstract:
In Nigeria, there are provisions in our Laws for the protection of the rights in property and the right to use and enjoy property. There have been efforts to control the use of property due to the realization of the need to protect the environment as a result of many years of uncontrolled human use and pollution of the environment in Nigeria, which have exerted cumulative pressures on the ecosystem. These pressures are increasing daily with population growth-leading to urbanization, deforestation, depletion of sea and land resources to produce food – increase in the use of machines and chemicals and other side effects of human activity and development. The aim of this paper is to examine the Nigerian Laws on environmental Laws for the good of the society and for the enhancement and maintenance of clean and healthy environment for all.

Keyword:
Property, Environment, Protection, Rights and Regulation.

1 Introduction

The freedom to use and enjoy property is guaranteed by Nigerian law but it is trite that the right cannot be absolute. The rights have to be regulated for the good of the society. Nigerian laws have been able to make provisions that can enhance the maintenance of a clean and healthy environment for all. The common law has also been able to provide some regulations in this regards. Thus there is great need for laws to be enacted to control the use of and activities on property and the environment. This is because the state and quality of the environment inevitably depends on the intricate process of the efforts at making a living and enjoying life. These activities have to be regulated so as to get the best out of the environment. In England, the common law has made attempts in this direction. In Nigeria, statutory provisions have been used to control and regulate these activities.

It is the aim of this paper to examine the common law provisions on the use of property and the law of nuisance and the use of property.

2 The Common Law Provisions on the Use of Property

The common law has been able to develop rules regulating and limiting the use of property. Restrictions on the use of property is very important, as unrestricted use of property by owners will lead to chaos. Thus, restrictions and regulations must be placed not only in the interest of other property owners but also in the interest of public health, safety, aesthetic, moral and general welfare of the community.

The common law rules regulating and limiting the use of property are in the law of nuisance, the rule in the case of *Rylands v. Fletcher,* the liability for Animals and fire and Trespass to land. We shall now examine these common law rules.

3 The Law of Nuisance

Nuisance is anything or person that causes annoyance, irritation, trouble, or inconvenience. Legally, what is a nuisance depends on the facts of each case as every inconvenience, irritation or annoyance is not actionable as nuisance. Thus, a nuisance is any unreasonable conduct that interferes with the convenience, lives, safety, comfort or enjoyment of others. In the case of *Walter v. Selfe*[1], Knight-Bruce VC defined nuisance to be:

> *An inconvenience materially interfering with the ordinary comfort physically of human existence, not merely according to elegant or dainty modes and habits of living, but according to plain and sober and simple notion among the English people.*

The law of nuisance deals with the lawful activity of a land owner on his own land which affects the enjoyment of another land owner. Therefore, in order to make sure that every property owner enjoys his property to the maximum, without infringing on others' freedom, the law of nuisance imposes some restrictions on the land owner's use of his land. In the case of *Thompson Schwab and Another v. Caslaki and Another*[2]*,* Evershed M.R. stated that:

> *... the conduct of the defendant which results in the nuisance is of itself not necessarily or usually unlawful. A private nuisance may be and usually is caused by a person doing on his own land something which he is lawfully entitled to do. This conduct only becomes a nuisance when the consequences of his acts are not confined to his own land but extend to the land of his neighbour,*
>
> 1. *Causing an encroachment on his neighbour's land when it closely resembles trespass.*
> 2. *Causing physical damage to his neighbour's land or buildings or works or vegetation upon it, or*
> 3. *Unduly interfering with his neighbour in the comfortable and convenient enjoyment of his land.*

[1] (1851) 64 E.R. 849 at 852
[2] (1956) 1 W.L.RJ. 335 at p. 338

Generally, nuisance involves a condition which unduly interfers with the use and enjoyment of land. Thus, it was stated that:

> *The essence of nuisance is a condition or activity which unduly interferes with the use and enjoyment of land… it is an act or omission which is an interference with, disturbance of or annoyance to a person in the exercise or enjoyment of (a) a right belonging to him as a member of the public when it is public nuisance or (b) his ownership or occupation of land or of some easement, profit or other right used or enjoyed in connection with land, when it is a private nuisance.*[3]

Thus, a nuisance may be public or private. Usually public nuisance affects the generality of the populace.[4] It is penal in nature and it is enforced by the state, unless the individual has suffered over and above the generality of populace. Therefore, it is thought convenient to allow the state to seek redress for such inconvenience.

At Common Law public nuisance is defined as:

> *A misdemeanor… either by act or omission to cause substantial annoyance to the subject of the Crown in general by exposing to danger or in other ways affecting injuriously their lives, health, property or even morals or by obstructing them in the exercise of the rights common to all subjects of the realm.*[5]

Nuisance is a case law and can only develop when there are cases in court which widens the frontiers of available doctrines. Hence, it is trite to say that the legislature is the only pulse of the society to maintain the balance between the tedious process of growth of the common law and the needs of a technologically and economically competitive world.

Flowing from the above, it can be asserted that under the common law the law of nuisance has been able to regulate the use of property by owners in such a way that they do not cause discomfort to others and diminution of property. But, it is not the case that any mode of user which lessens the comfort or endangers the health and safety of a neighbour and his property will amount to nuisance. This is as a result of the fact that, the law of nuisance does concede some degree of discomfort and pollution in certain cases.[6] Although, the development of the law of nuisance has not been astute in making sure that the degree of tolerance required is reduced to the barest minimum.

4 The Rule in the Case of Ryland v. Fletcher

[3] Clark and Lindsell on Tort, 14th Edition p. 803 Article 1391
[4] The Criminal Code Act, Cap. 38, Laws of the Federation of Nigeria
[5] Turner, J. Ed. Outhnes of Criminal Law Cambridge (Cambridge 1958) p.389
[6] St. Helen's Smelting Company v. Tipping (1865) 11 H.L. Cases.

This rule which evolved from the case of *Ryland v. Fletcher,*[7] was propounded by Blackburn J. in the court of first instance as follows:

> *A person who for his own purpose brings on his land and collects and keeps there, anything likely to do mischief if it escapes must keep it in at his peril and if he fails to do so, he is prima facie liable for all the damage which is the natural consequence of its escape.*

This rule is that of strict liability. Whenever the requirements of the rule are satisfied, liability will lie whether the defendant was negligent or not. The rule is aimed at protecting the property of a person from damage caused by the escape of non-natural things from the land of another. In the case of *Read v. Lyons,*[8] it was held that personal injury does not come under the rule. Thus, it could be stated that the rule represents another of the methods devised by the common law to control and regulate the use of private property.

Under this rule, is the issue of non-natural user of land. However, whet is non-natural user of land is not fixed. It is capable of changing as technology develops and in accordance with the requirements of the age. Thus what has been regarded as non-natural may subsequently, due to technological development and the needs of the society be regarded as natural user.[9] As a result of this fact, *Ryland v. Fletcher*[10] as a rule can be said to be an inadequate remedy for regulating the use of property as it has not been able to respond quickly to the needs of the times.

Despite the above fact, it has been shown[11] that our courts have applied the rule in cases involving the petroleum industry, to protect the interest of land owners from dimunition due to petroleum operations. Despite the fact that petroleum operations may be regarded as done for the common benefit of all (a defence under the rule), it should not be forgotten that, in most cases, the communities whose land and environment are polluted suffer terrible hardships. In view of this, their sufferings require adequate compensation. Thus, the maxim *ibi jus ubi remedium* should apply.[12] However, there are statutory provisions regulating the operations in this sector.[13] Despite this, there exist some gaps that need to be filled.[14]

5 Liability for Animals and Fire

The owner of animals has duties to keep them in such a ways as not to constitute annoyance to his neighbours. This duty of the owner of animal is imposed by law. The common law has always recognized the effect of uncontrolled animals to the land. The common law has also developed what is called cattle trespass by which the keeper of cattle is under a duty at common law to keep his cattle within his premises. In such a case, if the cattle should stray to a neighbour's land to cause damage, the property owner may bring an action in trespass.

[7] (1947) A.C. 156.
[8] (1947) A.C. 156
[9] British Celanese v. Mint (1969) 2 All E.R. 1252
[10] Supra
[11] Adewale O. Rylands v. Fletcher and the Nigerian Petroleum Industry Vols. 8 and 9 J.P.P.L p. 37
[12] Ogbuigwe A.E. Compensation and Liability for Oil Pollution: Need for a Approach Vol. 3 J.P., P.L. P.7
[13] Petroleum (Drilling and Production) Regulations (L.N. 69 OF 1969).
[14] Dreper v. Hodders (1972) 2 Q.B. 56

Although the keeping of animals provide a variety of comfort and pleasure. However, where the animal is not properly maintained, it could cause damage to the environment and disrupt both the physical condition and the aesthetic beauty of our environment. The improved methods of raising animals, like piggery and poultry, is another source of pollution to the environment. Issues as stench pollution and noise pollution from animals may amount to nuisance which may cause the owner of such animals to be liable.[15]Naturally, some animals are destructive. The law conceed that where the animals are naturally on the land there will be no liability if they escape to cause damage. But where they had been brought on to the land by the land owner, he has a duty to make sure that they do not escape to go and cause damage on adjoining land. The law stands even if the owner knows or ought to know the savage disposition of his animals. Thus, the law is aimed at restricting the right to use and enjoy property for the common good of all.

With respect to liability for fire, the Fire Prevention Metropolis Act 1774-26 modifies the common law position to exonerate person who are not negligent in preventing the spread of fire. The law is to the effect that a land owner cannot ignore a fire that starts on his land. It is correct to state that the destructive effect of fire if uncontrolled is usually devastating. Therefore, it is important to prevent its spread. As a result, the law imposes a duty on the land owner from whose land a fire starts to prevent it spread to adjoining land.

6 Trespass to Land

Every unauthorized invasion of property is trespass. However, minute an invasion of property is, it is trespass as long as the invasion is unauthorized.[16] The entry into the property of another and projecting substance from one's land to that of another are regarded as trespass to land. Thus the main aim of the law of trespass is to prevent one's property from unauthorized interference and from pollution created by his neighbour. In the case of *Gregory v. Piper,*[17] some rubbish were placed by the defendant on his land. He left the rubbish to dry. It was his intention to dispose of them properly when they are dried. Unfortunately, the rubbish were blown by the wind into the land of his neighbour. The court held the defendant liable.

The restrictions provided by the common law are necessary in the interest of the health, safely, religions, morals and general welfare of the people. Thus, it was stated by *Luxmoore, J. in the case of Vanderpant v. Mayfair Hotel Company Limited,*[18] that:

> *"every person is entitled as against his neighbour to the comfortable enjoyment of the premises occupied by him."*

Therefore, an invasion of the comfortable enjoyment of property will amount to trespass.

The foregoing discussions, support the fact that the Common Law as applicable to Nigeria has been able to provide some restrictions on the right to use and enjoy property in Nigeria. Although, there are not many cases that have been before the courts on these topics, some form

[15] Abiola v. Ijeoma (1970) 2 All N. L.R. 268
[16] Entick v. Carrignton (1765) 19 St. Tr. 1030
[17] (1829) B & c 591.
[18] (1930) 1 Ch. 138

of control have been achieved in respect of the few cases that were before the courts especially with respect to the law of nuisance and the use of property.

7 The Law of Nuisance and the Use of Property

Where an action in nuisance is founded on the use of property which has causes inconvenience, annoyance or discomfort, such inconvenience, annoyance or discomfort, must be shown to be substantial. The classic formulation of the rule is that of *Luximoore J. in the case of Vanderpant v. Mayfair Hotel Co. Ltd..*[19] According to Luxmoor J.:

> *Every person is entitled as against his neighbour to the comfortable and healthy enjoyment of the premises occupied by him, and in deciding whether, in any particular case, his right has been interfered with and a nuisance thereby caused, it is necessary to determine whether the act complained of is an inconvenience materially interfering with the ordinary physical discomfort of human existence, not merely according to plain and sober and simple notions obtaining among the English people.*

This rule has been cited with approval in several cases in Nigeria. In the case of *Moore v. Nnado,*[20] the plaintiff alleged nuisance by the defendant. According to the plaintiff, the defendant caused excessive noise in his neighbouring palm wine bar by playing stereograms unreasonably loudly until late every night. That as a result of the noise, he had been compelled to seal up his louvre windows with sheets of plywood and to spend most of his time in the back yard to his house.

It was held by the learned judge that:

> *"the degree of nuisance from the defendant's premises was more than the plaintiff is expected to tolerate in the circumstances."*

Moreover, in the case of *Abiola v. Ijoma,*[21] the plaintiff and the defendant were occupying adjoining premises in a residential area in Surelere, Lagos State. As a pastime, the defendant kept poultry at the back of his house. In 1969, he purchased four hundred day-old chicks which he kept in pens erected against the boundary wall. The boundary wall was about five feet from the plaintiff's house. It was claimed by the plaintiff that excessive noise made by the chickens in the early hours of the morning disturbed his sleep. He also claimed that nauseating smells from the pens interfered with his comfort. Therefore, he sought damages and an injunction to restrain the alleged nuisance.

The court awarded the plaintiff damages and an injunction restraining further acts of nuisance by the defendant.

Furthermore, in the case of *Tebite v. Nigeria Marine & Trading Co. Ltd,* the issue of interference with enjoyment of land in the Nigerian context was examined by Atake J. In this case, the

[19] (1930) 1 Ch. 138
[20] (1967) F.N.L.R 156
[21] (1970) 2 All N.L.R. 268

plaintiff, a legal practitioner, occupied premises at No. 11 Robert Road, Warri, which he used as his chambers. At No. 9 Robert Road, the defendants had a workshop where they carried on the business of boat building and repairing. An action for nuisance was brought by the plaintiff against the defendants. The plaintiff alleged that by operating their machines continuously for several hours a day, the defendants had persistently caused to emit from their workshop loud and excessive noise and noxious fumes which diffuse his premises and cause him much discomfort and inconvenience.

It was held by the learned judge that, in respect of both the noise and the smells, substantial interference with the plaintiff's comfort and convenience had been proved, and he was entitled to damages and an injunction to restrain continuance of the nuisance.

8 Conclusion

This paper probably has succeeded in discussing the restrictions on the right to use and enjoy property in Nigeria and in examining the common law provisions on the right to use and enjoy property. We have been able to show that although there are not many cases that have been before the courts, some form of control have been achieved and the freedom to use and enjoy property is guaranteed by Nigerian Law. Although there exist some gaps that need to be filled. However, it has been shown that Nigerian courts have been able to make decisions that can enhance the maintenance of a clean and healthy environment for all. Moreover, the common law has also been able to control the right to use and enjoy property.

The impact of amendments to the Collective Investment Act of 2003 on the share-price of Listed Property Funds in South Africa

Charles Muzi Nsibande[1]

[1]Principal Surveyor, Bogoje Properties,
Johannesburg, South Africa

Email: m_nsibande@yahoo.co.uk

Abstract:
The aim of the research is to determine the impact of the ammendments to the Collective Investment Act on the performance of the listed sector on the Johannesburg Securities Exchange (JSE) Limited. The ammendments were made in 2003 and in 2008. The ammendments made in 2003 proposed changes to the capital structure of Property Unit Trusts, to be able to gear up to 30% of their underlying value. The literature reviewed in the research suggested that there should be an impact on the performance of the shares and returns of the companies when there is change in the capital structure of the listed companies. Three measures were applied to the changes to determine if there has been significant impact: risk measure using Sharpe adjustments; value at risk measure; and events studies. The aim of using the three measures is to determine without doubt that changes made to the capital structure of the Property Unit Trusts impact on the performance of the listed companies. Comparison was made for the period 1996 to 2003, before the announcement of the amendments to the Collective Investment Act, and the period 2003 to 2008, after the announcement. The research is in progress and will be completed in the course of 2012. This paper introduces the framework for the research and the literature reviewed. A second paper will be prepapered for future presentation, covering the results and conclusion.

Keywords:
Collective Investment Act, Property Loan Stocks, Property Unit Trusts, Return, Risk

1 Introduction

There are two types of listed property companies in South Africa: Property Loan Stocks (PLS) and Property Unit Trusts (PUT). These companies are listed on the Johannesburg Securities Exchange (JSE) Limited under “Financials – Real Estate”. The South African listed property sector has delivered attractive returns over recent years, but neither of the current structures, compared to Real Estate Investment Trusts (REITs), offers international investors the uniformity and simplicity which would facilitate international investment.

 ISBN: 978-1-84219-840-7 .

1.1 Property Unit Trusts (PUTs)

A Property Unit Trust is a portfolio of investment grade properties which date back to 1969 when two trusts were established and listed on the JSE Limited. Each portfolio is listed on the JSE under "Real Estate Investment Trusts", A PUT generates value for the investor in two ways: through rental income of the properties in the portfolio, and through the appreciation in the values of these properties over time.

Investors in PUTs therefore get a share of the portfolio's rental income in the short term, while the value of the units themselves increase in the longer term, mainly because of the rising value of the properties in the portfolio.

PUTs are managed by experienced and reputable management companies, responsible both for the day-to-day operation of the properties and leases, and for the investment strategy of the trusts.

Today, the sector comprises six listed trusts, with a total market capitalisation of over (as at beginning of 2008) ZAR24-billion. The prices of listed PUTs are quoted on the JSE Limited (SA) and are published in the pages of most daily newspapers, under the "Real Estate" heading.

1.2 Property Loan Stock companies (PLSs)

Property Loan Stock companies invest solely in property. As with all other companies property loan stocks are subject to the Companies Act, JSE regulations and are governed by their own memorandum and articles of association.

The main difference between property loan stock companies and other companies is the method whereby the owners fund the company. When you purchase a linked unit in a property loan stock it is comprised of part share and part debenture (or loan). The debenture (loan) portion of the linked unit earns interest at a variable rate. The interest comes from net income (after expenses), which the loan stock company achieves from rental streams from the properties in which the company invests.

Usually property loan stocks distribute all their revenue profits, mainly through debenture interest with the balance being paid out as a dividend. Distributions are paid as often as quarterly by several property loan stock companies, and at the very least twice during each fund’s financial year. These regular distributions provide a steady cash stream and are tax transparent.

The conditions and terms of the debentures, including rate of interest payable and repayment dates are governed by the debenture trust deed and independent trustees are appointed to look after the interests of debenture holders.

1.3 Comparison with Real Estate Investment Trusts (REITs)

There are a number of common features between PUTs and the international Real Estate Investment Trusts, or REITs,, which include the distribution of income from the property investments in the form of net rental or an interest distribution, which is taxable in the investor’s hands; restrictions on the type of assets that the trust invests in

(typically types of property investments); guidelines on the amount of income that needs to be distributed; and limitations on the level of debt on the balance sheet.

More recently, implementation by the JSE of the FTSE-JSE Africa Index series has resulted in a "Real Estate" sector which includes PUTs, PLSs as well as property holding and development companies, although the JSE continues to run a sub-index specifically for PUTs. With the recent promulgation of the Collective Investment Schemes Act on 2008, PUTs are technically collective investment schemes in property, but are still referred to as PUTs as the nature of the investment remains the same.

2 The research problem

The existing approach to capital regulation in the United States of America and European Union, based on the so-called “Basel I” and “Basel II”, was identified by many regulators and commentators as one of the key factors contributing to the global financial crisis of 2008. Under the pre-crisis capital adequacy rules, the minimum regulatory capital levels of banks were insufficient in relation to the exposures and actual losses of the banks suffered during the financial crisis. Also the quality of regulatory capital appeared often insufficient to absorb bank losses effectively. The capital adequacy rules of Basel I and Basel II did not adequately capture risks posed by bank exposures to transactions such as securitizations, derivatives and repurchase agreements or take into account the systemic risks associated with the build-up of leverage in the financial system. Moreover, Basel I and II focused on capital only, with no internationally agreed quantitative standards for liquidity. This is often perceived to have been a serious shortcoming when the financial crisis unfolded in 2007 and liquidity evaporated in the key funding markets used by many banks and bank-sponsored vehicles.

Property unit trusts (PUTs) and property loan stocks (PLSs) are convenient, listed vehicles for investing in property. Amendments to legislation introduced the Collective Investment Schemes Control Act of 2003, allowing PUTs to gear up to 30% of the value of their underlying properties. This makes PUTs indistinguishable from PLSs in terms of their capital structure (debt and equity structure) so that there is a need to undertake a comparable investment analysis of the performances of the two types of listed property funds. Before 2003, PUTs were allowed to gear up only to five percent of their property value, whereas PLSs were allowed to gear up to any level acceptable by the management company. This modification has brought PUTs’ risk profile to a similar level to that of PLSs.

The aim of the research is to determine the impact of the amendments of the Investment Collective Act on the performance of the PUTs and PLSs using three methods, namely:

a. Risk adjusted returns
b. Value at Risk
c. Event studies

3 Literature review

3.1 Risk and Return

Risk can be classified as either systematic or unsystematic. Systematic risk affects all investments to a certain degree and can be eliminated through diversification (Ross, Westerfield and Jordan, 1998). Examples of systematic risk are uncertainty about general economic conditions, interest rates, inflation and legislative risk. An estimation of systematic risk is crucial for determining the expected return of an asset. Ross *et al* (1998) states the expected return of an asset depends only on the asset's systematic risk. The specific measure of systematic risk is the beta coefficient. The beta coefficient tells how much systematic risk a particular asset has in comparison to an average asset.

3.2 Capital Structure

3.2.1 Modigliani Miller Propositions

According to Modigliani and Miller's first proposition, the capital structure of a firm has no significance on the total value of the firm where taxes are ignored (cited in Bodie, Kane and Marcus, 1999). As has been discussed above, taxes were ignored on this research so "M & M Proposition I" is applicable when comparing PUTs and PLSs. The market value of PUTs and PLSs should be independent of the securities used to provide the financing but should be dependent on the earnings flow generated by the company's investments. Therefore, PUTs and PLSs with the same risk, borne by the same type of properties, having the same asset value and producing the same cash flow, should yield the same return.

In the research, the weighted average cost of capital (WACC) is:
$WACC = (E/V) \times R_E + (D/V) \times R_D$
Where E is the proportion of equity
D is the proportion of debt
V is the sum of E and D
WACC can also be defined as the required return on the firm's assets.

Replacing WACC with R_A, the return on assets and rearranging the above formula gives Modigliani and Miller Proposition II in the no-tax case:

$$R_E = R_A + (R_A - R_D) \times D/E$$

The formula states that the cost of equity depends on the required rate of return on a firm's assets, R_A (WACC), the firm's cost of debt, R_D, and the firm's debt equity ratio (Ross *et al*, 1998).

Before the amendments to the legislation governing PUTs, PUTs had no significant borrowings, meaning D = 0, implying $R_E = R_A$.

3.2.2 Security Market Line

The cost of equity (Ross *et al*, 1998) from the Security Market Line is:
$$R_A = R_f + (R_M - R_f) \times \beta_A$$

 ISBN: 978-1-84219-840-7 .

Where β_A = firm's asset beta, a measure of the systematic risk of the firm's assets
R_f = risk free rate
R_M = market risk

According to the Capital Asset Pricing Model, the most widely used means of estimating equity hurdle rates (Harris and Marston, 2001) is:

$R_E = R_f + (R_M - R_f) \times \beta_E$
Where β_E = Equity beta.

Assuming no tax,
$\beta_E = \beta_A \times (1 + D/E)$

which explains the impact of financial leverage on the cost of equity.

3.3 Risk Adjusted Returns

The calculated average returns are not accurate so it is necessary to adjust for risk in order to make meaningful comparisons. Two measures for risk adjustment are discussed below.

3.3.1 Sharpe Measure

Ross *et al* (1988) described Sharpe's measure as a measure that compares entire investment portfolios by using total risk to adjust the returns.

Sharpe measure = $(r_P - r_f)/ \sigma_P$
where r_P = the portfolio return
r_f = risk free return
σ_P = standard deviation

3.3.2 Traynor Measure

According to Ross et al (1988), the Traynor measure uses only the systematic risk to adjust the returns.

Traynor measure = $(r_P - r_f)/\beta_P$
where r_P = the portfolio return
r_f = risk free return
β_P = beta of the portfolio

Bradfield (2003) observed that historical data over a longer period than five years may be of little relevance because the nature of business risks undertaken by companies over long periods changes significantly. He recommended a period of five years for calculation of beta coefficients. Hence, the both the Sharpe measure and the Trayner measure were used to calculate the risk adjusted returns of the PUTs and PLSs over the two periods (1996 to 2003 and 2003 to 2008).

3.4 Value at Risk

The Sharpe and Traynor Measures above are not the latest methods commonly used in portfolio performance evaluations (Alexander and Baptista, 2003). The more common measures use value at risk (VaR), defined by Alexander *et al* (2003) as a "measure of the additional average rate of return that investors would have earned if they bore an additional percentage point of VaR by moving a fraction of wealth from the risk free security to the portfolio of risky securities that they have selected".

Alexander *et al* (2003) explained that evaluating performance of portfolios using VaR is useful for practitioners and researchers because the ranking differs notably from the one arising from the Sharpe ratio, since VaR takes into account the probability density function of the portfolio's rate of return.

Chow and Kritzman (2002) observed that, in portfolios that hold long positions in assets with typical returns and risk profiles, the assumption of portfolio log-normality does not seriously misstate value at risk.

3.5 Portfolio Theory

Markowitz (1957) identified the benefits of a collective measure of the importance of all of an investor's holdings. He observed that, if the covariance of the expected returns of the investments is negative, when one investment performs well while another does not, the volatility or degree of risk inherent in the portfolio will be minimised. Bodie *et al* (1999) explained that the risk of a portfolio can be minimised for a given expected return by the selection of a portfolio along the efficient frontier. All portfolio managers wish to hold their investments along the efficient frontier to maximise the possible expected return for a given level of risk. They further explained that the risk that is minimised by portfolio theory is unsystematic risk or non-market risk.

3.5.1 Risk Sharing and Risk Pooling

Investors strive to achieve the highest expected returns for a particular risk by diversifying risk through reducing the value that is at risk within the portfolio. Typically in property investments, a diversification strategy would include diversification across geographical regions, types of properties (retail or offices) or different grades of properties.

In risk pooling, the diversification is not sufficient to reduce the value that is at risk within the portfolio. To achieve risk sharing, an investor must spread his portfolio across shares that have negative correlation coefficients.

3.6 Events Studies - Theory of abnormal returns

The theory of abnormal returns is based on the Capital Asset Pricing Model of William Sharpe (1962). The model calculates expected returns of a portfolio and the residual or abnormal value on the return is referred to as abnormal return. There have been adjustments to the Sharpe model, notably Black's model (1972) which modified the risk free part of the Sharpe Model. Black made observations that post world war markets, the risk free factor overstates the expected returns. For purposes of this research, the

Sharpe model was applied in the calculations of expected returns as it remains an acceptable finance model in calculations of expected returns. In addition, the Sharpe model is much easier to compute for the JSE Limited's stocks and the model has not been disproved.

3.7 Capital Asset Pricing Model (CAPM)

3.7.1 Sharpe Model

A model that describes the relationship between risk and expected return and that is used in the pricing of risky securities.

The general idea behind CAPM is that investors need to be compensated in two ways: time value of money and risk. The time value of money is represented by the risk-free (r_f) rate in the formula and compensates the investors for placing money in any investment over a period of time. The other half of the formula represents risk and calculates the amount of compensation the investor needs for taking on additional risk. This is calculated by taking a risk measure (beta) that compares the returns of the asset to the market over a period of time.

3.7.2 Black's Model

Black, Jensen and Scholes (1972) have given evidence that the Sharpe's CAPM has not described expected returns adequately in the "post-war" period, and that the following equation seems to fit the data better than Sharpe's CAPM:

$$E(Rit) = E(Rzt) + \beta i[E(Rmt) - E(Rzt)] ,$$

for any security i, where Rzt is the return on a minimum variance portfolio of risky assets which are uncorrelated with the market portfolio.
Rmt is the market return.

In other words, Black et al found evidence that high beta securities tend to be overvalued, and low beta securities tend to be undervalued. One possible interpretation of this result is that high beta stocks tend to be low yield stocks, and what is really happening is that low yield stocks are overvalued, and high yield stocks are undervalued. If this were the case, then the result would be associated with corporate dividend policy rather than with factors such as capital structure that affect the returns of a corporation's common stock.

Described below are the details of the application of Black's model in event studies as described in Brown and Warner (1980). Brown *et al* (1980: 208) stated that "the market and risk adjusted returns' model presumes that some version of the Capital Asset Pricing Model generates expected returns. In Black (1972) two parameter Asset Pricing Model, $E(R_{it}) = E(R_{zt}) + \beta_i[E(R_{mt}) - E(R_{zt})] = K_{it}$ for any security i, where R_{zt} is the return on a minimum variance portfolio of risky assets which are uncorrelated with the market portfolio.

R_{mt} is the market return.

In Black's model, the abnormal return ε_{it} is equal to $R_{it} - [R_{zt}(1-\beta_i) + \beta_i R_{mt}]$

Therefore, the return which is realized on security i in period t, Rit is given by

$R_{it} = K_{it} + \varepsilon_{it}$,

Where K_{it} is the expected return given by the model above, and ε_{it}, which is the component which is the abnormal or unexpected."

4 Research Methodology

4.1 Collection of Data

Data on monthly stock prices and actual dividends paid were collected for the period 1 January 1996 to 31 December 2008. Data was obtained from I-net Bridge, Investment Property Databank and published annual reports, mainly Provest's PUT and PLS Report and Catalyst's Listed Property Sector Monthly Overview.

For the value at risk analysis, the underlying value of each PUT and PLS with market capitalisation in excess of R600 million was tracked over the 15-year period of the research. The data on PUTs, from I-net Bridge, was available from January 1993.

4.2 Analysis of Data

4.2.1 PUTs versus PLSs Returns' Analysis

From the monthly closing stock prices, the annual returns were calculated as:
% Return = ((closing stock price + dividends paid in period – opening stock price)/closing stock price) x 100%.

Annual returns were analysed to determine the difference in performance of PUTs from that of PLSs. This was because, firstly, annual returns show strong normality characteristics from the NCSS analysis; and, secondly, annual returns eliminate auto-correlation, as observed by Gilberto (2003).

The returns were computed over one-year, three-year, five-year, seven-year, 10-year and 15-year periods for both PUTs and PLSs. The results were then analysed using NCSS software to determine whether there is a statistically significant difference between the two samples. The two-sample t-test was used to determine the difference between PUTs and PLSs at 0.05 significant levels.

The returns were then adjusted for risk using the Sharpe measure for the 18 months from July 2003. The risk free rate of 7.82% was used, that is, the R153 bond rate as at 30 December 2004, the date at the end of the period under study. The same risk free value was used in all risk adjustment of returns.

The annual risk adjusted returns were calculated as:
(% Return at year n – 7.82%)/ Standard deviation for year n

The monthly risk adjusted returns were calculated as:
(% returns at month n – 7.82% * n/12)/ Standard deviation for month n.

The NCSS software was used to determine whether there was a significant difference between the two samples of PUTs and PLSs at the 0.05 significance level.

In order to analyse the impact of the amendment to the Collective Investment Act that allowed PUTs to leverage as much as 30% of their underlying values, returns were then analysed for the period July 2003 to December 2008. From the monthly closing stock prices, monthly returns were calculated as:

% Return at month n = ((closing stock price at month n + (dividends paid during period)*n/6 – opening stock price)/closing stock price at month n)* 100%.

4.3 Value at Risk Analysis

Kollenberg (2002) described a procedure for the computation of VaR to determine whether diversification has been achieved as the underlying asset value of the fund increased. The VaR is ascertained as the percentage volatility multiplied by the total underlying asset value of the fund. VaR values are then plotted as a function of the underlying value of the fund. If VaR increases at a rate equal to the growth of the fund value, then no diversification has been achieved. However, if the VaR increases as the fund grows, but at a lesser rate, then diversification has been achieved. This is measured by calculating the slope of the least square regression of the VaR as a function of the underlying value of the fund.

Value at Risk analysis was completed for the period 1996 to 2003 and for the period 2003 to 2008. Comparison of the two periods was made.

4.5 Event Studies Analysis

The SENS announcement was our primary source of information that could impact on share-price on the date of the announcement or the event date. Brown and Warner (1980, 1985) gave a good background on the use of event studies' methodology in measuring share-price performance. Brown *et al* gave details of the methodology and explained the different circumstances and suitability of each method.

In South Africa, the Event Studies methodology has been widely applied to share-price analysis of companies on the JSE Limited exchange. The methodology has been applied to analysis of share-price reaction to equity financing (Bhana, 2002), analysis of share-price reaction to key executives lay-offs (Bhana, 2003a), analysis of share-price reaction to layoffs (Bhana 2003b) and performance of corporate restructurings and spin offs (Bhana, 2004).

The most aggressive analysis of event studies, the use of market adjusted returns, was applied to get the most effective analysis of the impact on the share-price. The market and risk adjusted returns model takes into account both market-wide factors and systematic risk of each sample security.

4.5.1 Application of the CAPM in Events Studies analysis

For each security in the sample, the return is regressed from day -20 through +10 against the returns on the market portfolio during the corresponding days. This model regression yields a residual in each event-related day for each security. For each security, the market model residual is its measure of abnormal performance.

4.5.2 Cumulative Average Residuals (CARS)

When there is incomplete prior information about when an event occurs we can use of cumulative average residuals (CAR) technique as employed by Fama, Fischer, Jensen and Roll (1969). The technique focuses on the average market model residuals of the sample securities for a number of periods around the event. The cumulative average residual is defined as the value of the cumulative average residual of the previous event-day plus the current value of the average residual, AR_t.

$$CAR_t = CAR_{t-1} + AR_t$$

For a given sample and a given level of abnormal performance, we take the average market model residuals and begin cumulating them in day -10; accumulation then occurs for every day through to +10. For each procedure (share-price) the accumulation yields 21 cumulative average residuals, one for each event-related day.

When the CARs are plotted on a graph ("CAR plots"), when there is abnormal returns, we get fractiles (one large spike (up or down)) on the event day.

5 Expected results

It is expected that the amendments in the Act that has allowed the changes to the capital structure of the PUTs and PLSs will have an impact on the performance of the returns and share-price of the listed companies. The risk profile of the companies is expected to change hence the risk adjusted returns of the listed companies should reflect this change. The Value at Risk measure is also expected to give results showing that the risk profile, as a result of the change in the capital structure, has changed - due to the amendments to the Collective Investment Act.

From the results, it is expected that the risk adjusted returns of the PUTs should differ for the period 1996 to 2003 to the risk adjusted returns of the period 2003 to 2008. It is also expected that the values at risk for the different periods should also differ. In addition, it is expected that the impact of the announcement of the amendments to the Collective Investment Act should be different on the returns and share-price of the PUTs compared with the returns and share-price of PLSs.

IMPACT OF THE SOUTH AFRICAN GAUTRAIN ON PROPERTY VALUES

Oberholzer, R V[1] and Cloete, C E [1]

[1]Department of Construction Economics, University of Pretoria, South Africa

ABSTRACT

The Gautrain rapid rail project, providing a vital rapid rail link between Johannesburg, Pretoria and the OR Tambo International Airport, was at US$3000 million the largest construction project in Africa. Announcement of the project has led to widespread speculation on the anticipated impact of the project on the property market in areas surrounding the proposed stations. This study investigated the anticipated impact of the proposed Hatfield Gautrain Station on office property values in the Hatfield precinct in Pretoria. The research findings indicated a small positive impact on office property values. The overall anticipated impact of the Gautrain on the property environment was relatively small.

Keywords: Gautrain, property values, Hatfield, property market, Pretoria, South Africa, rapid rail.

INTRODUCTION

The introduction of the first Rapid Rail transit project in South Africa was announced in early 2000. The project that forms part of ten Spatial Development Initiatives (SDI's) is called the Gautrain Rapid Rail System with a total construction period of more than eight years to complete all the phases. The rapid rail system connects Johannesburg with Pretoria and the OR Tambo International Airport, providing a high speed alternative transportation mode to travellers.

Apart from the fact that the Gautrain project is expected to decrease the traffic congestion it is also possible that the project could have an impact on the property values surrounding the stations. The Hatfield station, located in the Hatfield suburb to the east of the Pretoria Central Business District (CBD) was selected as the research precinct. There is a number of mixed land uses surrounding the proposed Hatfield station.

IMPACT OF TRANSIT STATIONS ON PROPERTY VALUES

Booz et al. (1999:1) argue that the introduction of rail transit into a region often creates expectations about the impact of the rail project on property values. According to Brinckerhoff (2001:1) the impact of rail transit on property values has been studied from many perspectives, including analyses of different types of systems (e.g. rapid, commuter, light rail), of residential versus commercial impacts, and studies which

[1] chris.cloete@up.ac.za

have attempted to isolate both the positive and negative effects. Research studies that focus on the impact of railway stations on property values are often incomplete and limited with mixed findings (Booz et al. 1999; Debrezion et al. 2003). The reason why the studies usually have mixed and sometimes contradicting results are due to the different methods of analysis and the fact that projects in different locations will not have similar effects (Bows and Ihlanfeldt 2001; Banister 2005). The Hedonic pricing method is generally a preferred approach adopted to determine the impact of a transit station on property values as the method includes the physical characteristics of a property (Banister 2005; Boucq 2007; Debrezion et al. 2003). However, for the purpose of this study it is foreseen that the Hedonic price method technique will not be used to test the hypothesis, mainly because there is not enough information available to conduct the hedonic price method.

A number of research studies indicate that the introduction of a rapid transit station in a metropolitan area could have an influence on the economy and hence change the property values in the area (Damm et al. 1980; Brinckerhoff 2001; Czamanski 1966; Doherty 2004; Banister 2005; Cervero 2009; Debrezion et al. 2003). According to Booz et al. (1999:1) the effect of new fixed guideway transit investments is two-fold; firstly it improves the convenience of accessing other parts of a region and secondly, it enhances the attractiveness of property, increasing the likelihood that property can be developed or redeveloped to a more valuable and more intense use. There is however a number of research studies indicating an increase in property values as a result of introducing a railway station in a region (Damm et al. 1980; Brinckerhoff 2001; Czamanski 1966; Doherty 2004; Banister 2005). According to Debrezion et al. (2003:4) the positive impact of rail stations will decrease further away from the rail station causing a price curve to form.

Apart from the accessibly function, a number of underlying factors or pre-conditions have an influence on the impact of a railway station on property values (Cervero 2003; Doherty 2004). “Two factors having a positive influence on property values are the access advantage by rail transit and commercial services and two factors which have a negative impact are negative external effects such as noise, pollution and the unsightliness of stations and crime that might be higher near stations” (Bows & Ihlanfeldt, 2001:2). While the majority of researchers indicate that light railway stations do have a positive impact on property values, there is a school of thought indicating the opposite (Ryan 1999; Cervero and Duncan 2002; Doherty 2004).

A number of underlying pre-conditions need to be in place for a transportation project to have a positive influence on property values. These include the availability of attractive development sites, supportive planning policies and strong local economies (Doherty 2004; Cervero 2003). Other elements that could also have an influence on the impact of a transit station are the type of railway system (Cervero 1994; Landis et al. 1994; Debrezion et al. 2003) and the type of property market (Doherty 2004; Debrezion et al. 2003).

THE INFLUENCE OF TRANSIT STATIONS ON COMMERCIAL PROPERTY VALUES

Literature relating to the impact of rail transit on commercial property values demonstrates a similar result as the impact on residential property values due to the fact that there is no consensus among the outcomes of the studies. Commercial

property values are influenced by the return on investment the property provides to an investor. The return on investment is directly related to the rental income of the property (Schiller 2001; Downing 2001; NPEC 2004). Commercial property users have to optimize their production decisions in a spatial context and their spatial demand functions reveal willingness to pay for commercial space at particular locations (Ball et al. 1998:55).

A number of researchers indicated that there is a positive relationship between commercial property values and railway stations (Cervero and Duncan 2001; Nelson 1999). There are however several past studies (e.g. Falcke, 1978 as cited by Cervero and Duncan 2001; Landis et al. 1994) indicating that rail transit confers no measurable benefits to commercial properties. Other supporting factors as highlighted by Cervero (1994) and cited by Cervero and Duncan (2001:5) indicated that mixed use development projects were better performers than single developments. A number of research studies indicated that the impact of rail transit stations on retail property values tends to be more sensitive than the impact on office property values (Damm et al. 1980; Downing 2001). It is important to highlight that the impact on commercial property values, as with residential values, will only occur within a certain radius surrounding stations of approximately 1.6 kilometer radius (Cervero and Duncan 2001; Debrezion et al. 2003).

RESEARCH METHODOLOGY AND DATA USED

The research study was based on systematic observation and analysis of quantitative measurements and secondary data sources were used as part of the measurement instruments. Due to the fact that the quantitative research design was used it was imperative that only credible and reliable data be used as part of the analysis. The institutions that were used for the purpose of obtaining the necessary data are all credible institutions that have been in existence for a number of years. The institutions provided their methodologies in terms of their databases before the data were analysed. After an evaluation of the methodologies it was clear that all the methodologies used by the institutions were sound and unbiased.

The secondary data sources used as part of the analysis were:

- City of Tshwane Metropolitan Municipality (CTMM),
- South African Property Owners Association (SAPOA),
- Quarterly Rode Reports as published by Rode and Associates,
- Lightstone Property Database
- Investment Property Databank (IPD)
- City of Tshwane Hatfield Development Framework.

Quantitative research was conducted through a non-equivalent comparative control group design technique. The non-equivalent control group design is a scientific quasi-experimental research technique to determine the impact an intervention has on a control group that has not been exposed to the intervention, compared to another group that has been exposed. The interrupted time-series design was also used as part of the analysis when the necessary data was available. The interrupted time-series design represents an improvement on the pre-measurement and post-measurement design in that it keeps some of the threats (historical events, spontaneous development, instrumentation) at bay.

For each analysis a comparative market was identified. A comparative market (control group) was chosen with which to compare the Hatfield data. The difference in the two market areas will thus provide an indication of the impact. It was however imperative to choose locations within the City of Tshwane Metropolitan Municipality (CTMM) that have similar characteristics as the Hatfield market. Due to its characteristics the Brooklyn node was chosen as the comparative market for the impact on the values of office properties.

The information supplied by the secondary sources consists of a number of office property indicators which were selected according to their relevancy. Each Excel data sheet was scrutinised in order to determine any discrepancies or outlier that may exist in the time-series data. The data was divided between the measurements prior to and after the announcement of the Gautrain project. Thereafter, the data was analysed in order to determine the pre- and post measurement of each indicator. Both the Hatfield and the Brooklyn nodes were examined in order to create a comparative analysis. A series of graphs were plotted to visually display the results in a way that made it possible to draw certain conclusions from them.

ANTICIPATED IMPACT OF THE HATFIELD GAUTRAIN STATION ON THE OFFICE PROPERTY MARKET.

In order to measure the anticipated impact a selected number of office market indicators were analysed in the Hatfield and Brooklyn node. The Brooklyn node was chosen as the comparative precinct due to the fact that the Brooklyn node represents similar characteristics when compared to the Hatfield node.

The office property market is influenced by a number of indicators. However, for the purpose of this analysis, only some of the indicators (those that can be quantified) have been included. The result of the analysis should provide a good indication of the impact of the anticipation of the Hatfield Gautrain station on office properties in the Hatfield node.

Measurement of each indicator used as part of the analysis both before and after the announcement of the Gautrain EIA process in 2002 is summarised in Table 1. The table also provides an indication of the comparative impact as measured for each individual indicator.

Table 1: Summary of the office property market indicator analysis.

Indicator	Hatfield office property market analysis			Brooklyn office property market analysis			Impact
	Before	After	Difference	Before	After	Difference	
Total return on investment	15.5%	23.6%	8.1%	9.2%	21.1%	11.9%	None
Income return	12.3%	11.8%	-0.5%	11.8%	9.8%	-2.0%	Small
Capital growth	2.9%	10.6%	7.7%	-0.5%	10.4%	10.9%	None
Net income growth	5.0%	5.1%	0.1%	5.8%	7.7%	1.9%	None
Net income yield	11.4%	10.6%	-0.8%	9.3%	8.9%	-0.4%	None

Indicator	Hatfield office property market analysis			Brooklyn office property market analysis			Impact
	Before	After	Difference	Before	After	Difference	
Growth in capital value	9.4%	41.6%	32.2%	5.2%	30.8%	25.6%	Big
Vacancy rates	6.6%	4.0%	-2.6%	5.4%	2.3%	-3.1%	None
Rent per month							
Average	9.6%	9.2%	-0.4%	10.3%	8.2%	-2.1%	Small
A+ grade offices	10.9%	10.2%	-0.7%	11.0%	9.9%	-1.1%	Moderate
A-grade offices	10.7%	10.7%	0%	11.2%	9.6%	-1.6%	Small
B-grade offices	10.3%	9.0%	-1.3%	15.1%	7.9%	-7.2%	Big

Notes: If the Brooklyn node outperformed the Hatfield node the impact was captured as none.
If the Hatfield node outperformed the Brooklyn node by 1% or less the impact was moderate.
If the Hatfield node outperformed the Brooklyn node between 1% and 2% the impact was small.
If the Hatfield node outperformed the Brooklyn node by more than 2% the impact was big.

From Table 1 it is clear that the announcement of the Gautrain EIA process did not have a significant impact on the office property values in the Hatfield node. The Hatfield node outperformed the Brooklyn node in a number of indicators, but there are contrary results.

- The highest positive impact was measured in the growth in capital value as well as the rent per month in B-grade office buildings.
- A small positive impact was measured for the average office rentals, A-grade office rent and income return,
- A moderate positive impact was measured for the growth in capital value per square meter and the A+ grade rent per month.

Five out of the nine indicators indicated negative impact for office properties in the Hatfield node when compared to the Brooklyn node.

CONCLUSIONS

The anticipation of the Hatfield Gautrain station did not have a significant impact on the office property values in the Hatfield node. Although the Hatfield node did outperform the Brooklyn node in a number of indicators there were some indicators which proved the opposite. A number of indicators indicated a short-term positive impact just after the announcement of the Gautrain EIA process in 2002. The positive impact was however not sustainable and only lasted for approximately two to three years.

From the analysis it is thus clear that there is no substantial evidence to indicate a positive impact of office property in the Hatfield node in anticipation of the Hatfield Gautrain station. None of the indicators analysed indicated a drastic change in the income of office properties in the Hatfield node. As the value of an office property is

determined by the income the property can acquire, it is possible to conclude that the impact was very small or even non-existing.

This result supports the conclusion that research studies that focus on the impact of railway stations on property values often result in mixed findings (Booz et al. 1999; Debrezion et al. 2003). The reasons why the studies usually have mixed and sometimes contradicting results can be ascribed to different methods of analysis, but also the fact that projects in different locations will not have similar effects (Bows and Ihlanfeldt 2001; Banister 2005).

In addition, any possible positive impact may be neutralised by negative impacts., as there are both positive and negative influences resulting from rail transit developments. As pointed out by Bows & Ihlanfeldt (2001:2), there are advantages emanating from the increased accessibility of offices and markets, but also negative external effects such as noise, pollution and the unsightliness of stations and crime that might be higher near stations.

It is clear that any findings indicating either a positive or a negative impact of rail transit stations cannot be extrapolated to similar situations elsewhere, but that each case must be investigated on its own merits.

SHOULD PUBLIC SERVICE INFRASTRUCTURE BE VALUED FOR PROPERTY TAX PURPOSES?

J A du Preez[1], R C D Franzsen[2] and C E Cloete[1]

[1]Department of Construction Economics, University of Pretoria, South Africa

ABSTRACT

The imposition of property rates (i.e. property tax) on "public services infrastructure" (i.e. public utilities) in terms of the Local Government: Municipal Property Rates Act (Act no. 6 of 2004) of South Africa, enacted on 2 July 2005 gave rise to various questions, the most important of which can be summarised as follows:

- should public services infrastructure be valued and rated at all;
- what is the definition of plant and machinery – can, for example, both the sleepers of a railway and the rails be seen as plant and equipment;
- is, e.g., a telecommunication tower or mast considered to be plant and equipment;
- how should linear infrastructure for example pipelines and railway lines, crossing local government boundaries, be valued and taxed, given that values and tax rates are determined at local government level?

The valuation of infrastructure is, even at international level, not an easy task. It is concluded that the Property Rates Act should be amended to better reflect international best practice.

Keywords: property rates, public service infrastructure, South Africa, valuation.

INTRODUCTION

The enactment of the Local Government: Municipal Property Rates Act (hereinafter "Property Rates Act") on 02 July 2005 heralded a new era with regard to property rates (i.e. property tax), the most important local tax in South Africa.

In terms of the provincial legislation repealed by the Property Rates Act, property rates could be levied on one of three tax bases, A municipality could choose to tax on the value of land only, or on the improved value, or on the value of the land and improvements as separate rateable objects. In terms of the Property Rates Act the tax base is now uniform for all municipalities, namely "market value" (section 46(1)). It further states that property "must be valued in accordance with generally recognised valuation practices, methods and standards, and the provisions of this Act" (section 45(1)).

[1] chris.cloete@up.ac.za
[2] riel.franzsen@up.ac.za

Municipalities cover the total surface area of South Africa. This implies that, in terms of the Property Rates Act, all properties must be valued and is in principle rateable, unless excluded from the tax base. This Act defines "property" as follows:

"property" means –

(a) immovable property registered in the name of a person, including, in the case of a sectional title scheme, a sectional title unit registered in the name of a person;
(b) a right registered against immovable property in the name of a person, excluding a mortgage bond registered against the property;
(c) a land tenure right registered in the name of a person or granted to a person in terms of legislation; or
(d) public service infrastructure.

This paper discusses some of the issues regarding the valuation and rating (i.e. taxation) of so-called "public service infrastructure" (hereinafter "PSI"). PSI could be equated to "public utilities" – as will become clear from the discussion below.

Definition of PSI and lack of a definition of equipment and machinery

According to Grad and Grad (2005), public utilities have generally been defined as private business organisations that are subject to government regulation, which provide an "essential" commodity or service such as water, electricity, transportation or communication to the public. In the South African context PSI is limited to infrastructure which is "publicly controlled", in other words owned by or otherwise under the control of an organ of state, such as a municipality, a municipal-owned company or parastatal.

The Property Rates Act (section 1) defines PSI as follows:

"public service infrastructure" means publicly controlled infrastructure of the following kinds:

(a) national, provincial or other public roads on which goods, services or labour move across a municipal boundary;
(b) water or sewer pipes, ducts or other conduits, dams, water supply reservoirs, water treatment plants or water pumps forming part of a water or sewer scheme serving the public;
(c) power stations, power substations or power lines forming part of an electricity scheme serving the public;
(d) gas or liquid fuel plants or refineries or pipelines for gas or liquid fuels, forming part of a scheme for transporting such fuels;
(e) railway lines forming part of a national railway system;
(f) communication towers, masts, exchanges or lines forming part of a communications system serving the public;
(g) runways or aprons at national or provincial airports;
(h) breakwaters, sea walls, channels, basins, quay walls, jetties, roads, railway or infrastructure used for the provision of water, lights, power, sewerage or similar services of ports, or navigational aids comprising lighthouses, radio

navigational aids, buoys, beacons or any other device or system used to assist the safe and efficient navigation of vessels;

(i) any other publicly controlled infrastructure as may be prescribed; or

(j) a right registered against immovable property in connection with infrastructure mentioned in paragraphs (a) to (i).

This definition generally accords with what is understood to be "public utilities" in Canada (Grad, 2005; Kitchen, 2007), United Kingdom (Sanderson, 2005; McCluskey, 2007) and the United States (Grad, 2005), but read with the definition of "property" is unclear as there are overlapping property categories.

Some common features of all these utility companies include the fact that

- they are large in terms of both financial influence and geography, with values often exceeding billions of dollars (see McCluskey, 2007 – with reference to the United Kingdom),
- they usually cover multiple autonomous taxing jurisdictions,
- they have multiple units contributing to the operation of the firm, and the units are vertically and horizontally integrated, and
- these companies are often under some type of regulatory oversight, or have been in the past.

As stated above, PSI – as a category of "property" – is in principle rateable, and must therefore be valued. However, the current definition and features listed above combine to present policymakers and appraisers (i.e. valuers) with a significant challenge in dealing with these types of property from an appraisal and rating point of view.

Should utilities in principle be valued and taxed?

With reference to especially New Zealand, various authors, for example Young (1993), Sayce and Connellan (1995) and Dent (1996), queried the relevance of the valuation of public assets and, to a lesser extent, the reliability of such valuations. In citing the views of Auckland City Council, Young (1993) suggests that the value of, for example, infrastructural assets, is irrelevant in terms of accounting or operating efficiency, and that the cost of the valuation exercise is a waste of rate payers' resources. Pegler (1993) echoes this view that valuing assets of an infrastructural type is "largely an exercise in futility". In contrast, public utilities are valued and taxed extensively in, for example Canada, where these utilities are often taxed at much higher rates than residential properties (Bish, 2003).

In South Africa, the debate about the question on whether PSI should be taxable or not, was eventually settled by legal opinion that municipalities have a constitutional right to rate infrastructure (in terms of section 229 of the South African Constitution and excluding it per se would likely be unconstitutional). Therefore it was decided to retain it as "property" in the Property Rates Act. However, as certain types of PSIs were not valued and rated before the Property Rates Act became law, the risk existed that if rates are implemented in an irresponsible manner, it may have a substantial impact on the economy, as well as the fiscal environment at national and local

government levels. In 2009 a regulation was therefore enacted which limits the tax rate for PSI to a maximum of 25% of the rate determined for residential properties.

A key issue in South Africa is that valuation is not a national or provincial function, but a municipal responsibility. A "municipal valuer" must value only properties within a relevant municipality and prepare a valuation roll accordingly.

How should utilities be valued and rated?

Subsection 46(5) of the Property Rates Act, which was repealed in 2008, stated that where "available market related data is not sufficient to determine the market value of public services infrastructure, such public services infrastructure may be valued in accordance with any other method of valuation as may be prescribed." However, since its repeal, a municipal valuer have no choice (if the relevant municipality wants to rate PSI) but to determine market value using conventional methodologies. The valuation of network PSI (e.g., pipelines and railway lines) is problematic in South Africa, given that a municipal valuer only operates within a single municipality. In jurisdictions such as Canada (Grad and Grad, 2005; Kitchen, 2007) and the United Kingdom (Sanderson, 2005) it is solved by valuing the network and apportioning values. This can be done, for example, by length (km or metre), or freight volume for railway lines (Kitchen, 2007) and length and diameter for pipelines (Kitchen, 2007). These values are determined nationally (e.g. the Valuation Office Agency in the United Kingdom) or provincially (e.g. BC Assessment Canada) for the whole country or province. Such an agency has been advocated for South Africa to value unique properties (such as PSI) and to also monitor the uniformity and quality of valuations done by municipal valuers (Franzsen and McCluskey, 2000).

A proper definition (either in the Property Rates Act or in a regulation) of "equipment and machinery" (the equivalent of plant and machinery) does not exist, creating uncertainty regarding the nature and thus taxability of certain assets, which may or may not constitute PSI.

In South Africa tax rates are determined locally, but these are at least limited to a fixed ratio (0.25:1) in relation to the rates set for residential properties – as indicated above.

Given the nature of most types of PSI (there are exceptions), the comparable sales method cannot be used to value these properties. However, acceptable alternative methods exist (Horsley, 1991; Cooper, 1993, Thompson, 1993; Dent and Bond, 1993; Bond and Dent, 1996 and 1998; Sanderson, 2005, McCluskey, 2007).

The United Kingdom has managed to avoid many of the problems associated with valuing and rating public utilities by applying a uniform country-wide tax rate and statutory values, i.e. not requiring these utilities to be valued. This perhaps is in acknowledgement of the difficulties involved in determining realistic values for such assets. However, statutory values in the United Kingdom were abolished in 2005 (Sanderson, 2005; McCluskey, 2007). In the United Kingdom public utilities are presently valued utilizing refined versions of the income ("receipts and expenditures")

or cost ("contractor's basis" – annual equivalent of adjusted replacement cost) approaches (McCluskey, 2007)

The most acceptable method of valuation of PSI, where the income approach is not feasible, and which is used in various countries such as the United States, Canada and Australia, is the depreciated replacement cost (DRC). Depreciated replacement cost is defined (RICS, 2012:15) as "the current cost of replacing an asset with its modern equivalent asset, less deductions for physical deterioration and all relevant forms of obsolescence and optimization."

A limitation of the basic depreciated replacement cost approach is that it assumes replacement with assets substantially identical to those existing. The process of "optimisation" is an enhancement of the traditional like-with-like replacement approach that arrives at replacement costs using "modern equivalent assets" performing the same functions as the existing assets. It results in an estimate of the lowest possible cost of replicating existing services using modern materials and modern technologies in the most efficient asset configuration.

A method advocated – as a refinement of the cost approach - called the optimised replacement cost approach (ODRC), is considered by Thompson (1993) and Horsley (1991) to be the most satisfactory method available, particularly for infrastructural assets where there is no, or little, earning. The contractor's basis method, used in the United Kingdom (Sanderson, 2005; McCluskey, 2007) could also be considered.

Although the ODRC method is seen as as a workable method to value many types of PSI, this method is not totally free from criticism. Few advocates of this approach have provided practical examples of how it can be applied to the various types of assets, like heritage assets. It is also clear that, as the approach still requires the estimation of depreciation, the problems relating to this, outlined earlier, still remain. For example, in describing the method, Horsley (1994) simply mentions that the system or network can be depreciated on the basis of the service life of the individual components, but provides no explanation of how the latter is derived.

Also, certain infrastructure requires specialised inputs from, for example, engineers, to aid in the determination of value, thus adding to the cost of the exercise, which may well be beyond the budget of many local authorities.

CONCLUSIONS AND RECOMMENDATIONS

In the context of South Africa and learning from international experiences, some conclusions can be drawn regarding the valuation and rating of PSI in terms of the Property Rates Act:

- PSI should be valued;
- PSI remain rateable;
- the relevant definitions (e.g., 'public service infrastructure' and 'property') in section 1 of the Act should be reviewed;

- to enable valuers to properly value PSI, a definition of 'equipment and machinery' must be inserted in the Property Rates Act (or a regulation);
- only if the definitions referred to have been inserted and amended, as the case may be, will it be possible to value certain types of PSI and only when these are properly valued, can they be rated properly by municipalities.

The following recommendations are made:

- The definitions in the Property Rates Act referred to above should be amended to provide clarity regarding the nature and scope of PSI and equipment and machinery;
- optimised depreciated replacement cost (ODRC) or the contractor's basis could be considered as workable methods of valuation most types of PSI; and
- a national government agency, similar to the Valuation Office Agency in the United Kingdom or the provincial crown corporations in Canada (e.g. BC Assessment), should be established to value all linear PSI centrally, whereafter a pro rata apportionment to municipalities can be made for determining tax liability.

ABSTRACT

The Public Private Partnerships (PPP) markets in Australia and the UK are considered to be the most sophisticated in the World and used as a model for benchmarking against other countries. In addition the global financial crisis also meant many PPP financiers became risk averse to certain projects and in particular countries. The environment for major infrastructure projects, particularly in 'riskier' countries, has become more difficult. Research conducted by the Economist Intelligence Unit for the Asian Development Bank evaluated PPP policy and programs in a number of countries in the Asia Pacific. The study benchmarks the UK and Australian PPP environments with eleven developing or emerging countries including Bangladesh, China, Indonesia, Pakistan, Philippines, Thailand, Gujarat state in India, Kazakhstan, Mongolia, Papua New Guinea and Vietnam. The comparison was based on indicators developed to provide a sound evaluation of these countries. The indicators include; the legal and regulatory framework, institutional framework, operational maturity, investment climate, financial facilities plus a sub-national adjustment factor. The research methodology and the benchmarking results for each country are summarised.

Keywords: benchmarking; East Asia; public private partnerships.

INTRODUCTION

The quest for increased efficiency in public service delivery, the budget difficulties of many governments, and the growing receptivity of public opinion to the discourses for rehabilitating market regulations has led to a growing number of forms of association between the public and private sectors (Pongsiri, 2002; Bult-Spiering and Dewulf, 2006). These forms of association are generally referred to as Public Private Partnerships (PPP) and have become an integral part of the Federal and State Governments' procurement strategy in many countries (Raisbeck *et al*., 2010; Regan *et al*., 2011a; Regan *et al*., 2011b).

[1] mregan@bond.edu.au
[2] jismith@bond.edu.au
[3] plove@curtin.edu.au

While the PPP market in Australia is considered to be sophisticated and mature (Hodge, 2000; Duffield, 2005; Bult-Spiering and Dewulf, 2006), several major failures have emerged with infrastructure projects such as the Sydney Harbour Tunnel, Sydney Airport Rail and Sydney's Cross City Tunnel (Jefferies and McGeorge, 2009; Regan *et al*., 2011a). These experiences have sounded a warning for the introduction of new PPPs in Australia and taken together with the difficulty of financing new projects (Regan, et al, 2011b) has slowed the development of new PPP projects. These projects also provide a lesson for other countries in their quest to for new PPP projects to deliver infrastructure projects.

INTERNATIONAL POPULARITY OF PPPS

The concepts underlying PPPs have been used for decades worldwide to procure economic and social infrastructure (Kwak *et al*., 2009). The primary parties involved with a PPP project are the client, concession contractor and constituent members, which are often referred to as a Special Purpose Vehicle (SPV). Various forms of PPP have been found to exist such as Operation and Maintenance and Build Operate Transfer (Reijniers, 1994). Such terms are often used interchangeably, and sometimes they are subjected to differing interpretations. For example, Private Participation in Infrastructure (PPI) is the term used by the World Bank, and Private Finance Initiative (PFI) is used in the UK, Japan and Malaysia (Yescombe, 2007). The governments with the most developed PPP markets focus on using them to enable the public sector to achieve value for money (V*f*M). Value for money (Castalia and World Bank, 2007; Kwak *et al*., 2009) is driven primarily by:

- *risk transfer*: relieving government of the cost of asset based risks (i.e. risk directly associated with build or operating an asset lies with the private sponsor);
- *whole-of-life costing*: through whole-of-life costing the government can achieve optimization between capital costs and operating and maintenance costs, a realistic projection of total cost of ownership, and a way of comparing competing designs on a like-with-like basis;
- *innovation*: providing wider opportunity and incentive for innovative solutions as to how service requirements can be delivered; and
- *asset utilization*: developing opportunities to generate revenue from the use of the asset by third parties, which may reduce the cost that government would otherwise have to pay as a sole user.

In addition, typical benefits that can be achieved include:

- *introduction of the private sector's technical and managerial expertise*: The introduction of the private sector's expertise to the design, construct, maintain and operation of infrastructures and can provide efficiency gains;
- *improved quality of service and performance*: Under most PPP projects full payment to the private sector contractor will only occur if the required service standards are being met. International experience and particularly within Australia suggests that the quality of service achieved under a PPP is often better than that achieved by traditional procurement (Raisbeck *et al*., 2010; Regan *et al*., 2011a).

  This may reflect the introduction of competition, the better integration of services with supporting assets, improved economies of scale, the introduction of innovation in service delivery, or the performance incentives and penalties typically included within a PPP contract. In addition, the private sector has strong

incentives of profitability so that they will be more responsive to customers' needs and preference; and

- *enhanced public management*: The responsibility for providing public services is transferred from government to private sector, so that government can be more focused as regulators to monitor public services provided by the private sector. In addition, PPP introduces competition in providing public services and this reduces the cost of public services to ensure best value for money is achieved.

FINANCING PPPS AND VALUE FOR MONEY

The main reason why some governments pursue PPPs is to access finance that would otherwise not be available to them (Kwak *et al*., 2009; Regan *et al*., 2011b). However, this is not the case in practice, as access to finance by simply deciding to use a PPP is not always possible, especially in the current economic climate after the 2008 Global Financial Crisis (GFC) (Regan *et al*., 2011b). If an infrastructure provider is not assured user fees and government subsidies, it will not be able to recover its costs; the provider will simply be unable to raise the capital needed to build the project (Bennett, and Krebs, 1991). In essence, the government will not be able to attract private sector financing simply by deciding to undertake PPPs—cost-recovery over the project's life would need to be resolved before private capital can be raised (Regan et al., 2011b).

PROBLEMS WITH PPP

Despite the widespread acknowledgement that PPPs can provide value for money, there are also many academics and practitioners who have questioned this underlying proposition because under this arrangement there is a propensity for project complexity to increase and a probability of time and cost blowouts to occur (e.g., Grimsey and Lewis, 2004; Kwak *et al*., 2009). PPPs should be used only if they provide better V*f*M than traditional methods (European Commission 2003; HM Treasury 2006; Raisbeck *et al*., 2010). In Australia, for example, V*f*M is explicitly required before proceeding with a concession PPP project. Value for money is typically determined (a priori) by a public sector comparator (PSC). The PSC represents the net present cost of capital, maintenance, ancillary services, residual value and project risks for the contracted term (Partnerships Victoria, 2003).

The PSC has a risk element measured in terms of transferable and retained risk plus an assessment of competitive neutrality. The PSC estimates the hypothetical risk-adjusted cost as if a project were to be financed, owned and implemented by government. The key issue, however, rests on determining how the PPP can ensure that V*f*M is ultimately delivered to the taxpayer through a project or services provided by the private sector rather than the traditional government model.

The determination and assessment of V*f*M is a complicated process and is reliant upon high quality data, which should only be used after a degree of vigilant reflection (European Commission 2003). Although, it has been hard to establish proper comparisons with what a public sector alternative would deliver, results show that concession arrangements deliver only marginal savings (Institute for Policy Research, 2001; Regan *et al*., 2011b).

THE BENCHMARKING STUDY

The Economist Intelligence Unit (EIU) in 2011 was commissioned by the Asia Development bank (ADB) to develop a *Infrascope* benchmarking exercise for the

Asia pacific region to develop an index of 'PPP-readiness' in any specified country. This index would measure a country's capacity to execute infrastructure PPPs and was based on an analysis of the country's laws, regulations, institutions and practices over time (EIU, 2011:4) in carrying out PPPs.

The study selected four developed benchmark countries (Australia, Japan, South Korea, UK) and eleven developing countries in the Asia-Pacific (Bangladesh, China, Indonesia, Pakistan, Philippines, Thailand, Gujarat State in India[4], Kazakhstan, Mongolia, Papua New Guinea and Vietnam) and their readiness and capacity to undertake PPP projects in water, transport and energy sectors. The index is not designed as an investment tool for private financiers, as it is largely qualitative and aggregated data. The quantitative data, when used came from international statistical sources (mainly World Bank). The index comprises 19 indicators, 4 of which are quantitative and 15 are qualitative. The qualitative assessments were based mainly on primary sources contained in legal texts, government web sites, press reports and interviews.

However, even with its heavy qualitative bias, it is considered that the index does provide a basis for public-private discussions that can lead to better project conditions and policies (EIU, 2011:3).

The index was developed working with a group of regional and sector experts, whose knowledge of PPPs placed them in a good position to evaluate the categories of evaluation (see later). The expert group consisted of country specialists, policymakers, lawyers, consultants, development bank staff, regional and international PPP professionals (EIU, 2011:9).

The index measures readiness and capacity to implement PPPs over a project life-cycle divided into the following five components (EIU, 2011:9):

1. *Legal and Regulatory Framework* (for PPPs in that country);
2. *Institutional Framework* (the design and responsibilities of the country's institutions that prepare, award and oversee PPP projects);
3. *Operational Maturity* (the government's ability to uphold laws and regulations for PPP projects together with the number and success rate of previous projects);
4. *Investment Climate* (the country's political, business and social environment for investment in PPPs), and
5. *Financial Facilities* (for funding PPP infrastructure).

In addition, a sixth category was added to recognise the PPP activity at a regional level by adopting a stand alone *Sub-National Adjustment Factor.*

The weightings of each of the five categories are shown in Table 1. The 19 individual indicators under each category are also listed in Table 2 (EIU, 2011:10-11).

FINAL PLACINGS

The overall scores after taking account of the weightings for each category of assessment are shown in Table 2. It confirms that Australia and the UK with well established frameworks for PPP infrastructure projects are leaders in the field with their infrastructure market being defined by the EIU (2011) as being 'mature'.

Source: Adapted from EIU, 2011:6, 12.

A group of 3 countries plus a state (South Korea, Gujarat State, India and Japan) have *developed* markets, but at this stage, not to the same extent as the UK and Australia. The next group of seven *emerging* countries in this field have established themselves in the PPP market, but appear to need to pay more attention to the category of *legal and regulatory frameworks*. In this 25% weighted category these countries have not scored as well as those countries above them. Some countries have taken legal and legislative initiatives in this area, but India and China have not addressed these problems in a significant way. The next highest weighted category (20%) is the *Institutional and Regulatory* Framework. South Korea, Japan and India score reasonably well in this category, but further progress is needed. China and Vietnam are in the lower scoring order for this category. Attention is needed in this and the previous category to lift its performance. Dispute resolution and legal delays are also areas that need attention. Appendix A provides detail of each country's scores.

CONCLUSIONS

The EIU *Infrascope* study (2011) identifies the importance of institutions to the successful implementation of PPP programs. Two features are particularly important for success in PPPs. Firstly, a formal PPP policy framework with the creation of a dedicated PPP unit within a central policy-making arm of government. Second, a pipeline of projects at national and sub-national levels is needed. Also important are the capabilities of the PPP unit which has an important role in facilitating and advising line agencies. The study highlights the central role of institutions in PPP policy and program success.

ACKNOWLEDGMENT

EVALUATING TRUST AND RELATIONSHIPS AMONGST PROJECT PARTICIPANTS ON AN INDUSTRIAL PROJECT

James Olabode Bamidele Rotimi[1] and Rebeca Londero[2]

[1,2] *Construction Management Programme, School of Engineering, Auckland University of Technology, Private Bag 92006, Auckland 1142. New Zealand.*

ABSTRACT

A construction project team requires a considerable level of blending of its project stakeholders for its successful accomplishment. Blending is derived from an environment that promotes trust and relationship between key team players otherwise the team dynamics could fail to meet desired project performance objectives. The research evaluates the effectiveness of such blending on an industrial project completed in Auckland, New Zealand in 2010. It collates opinions of supervisory level personnel of two key project organisations (client and construction management organisation) involved in the implementation of the project. The project organisations had operated under a traditional procurement system but within the framework of a blended team. Perspective opinions of the supervisory level personnel are used to determine the level of trust and interactions that existed on the project and how this could impact on project deliverables. The findings of this investigation will benefit all stakeholders in construction projects. It provides an understanding of the pitfalls to achieving inter-organisational relationships which may position future project teams for better performance and overall project delivery successes.

Keywords: blended team, construction project, interaction, project team, trust.

INTRODUCTION

There is evidence to suggest that trust between project stakeholders is critical to success on construction projects. For example, the focus of managerial practices has shifted from managing technical processes to focusing on psychosocial determinants of project performance. Although this trend tends to strain project management theory and practice (Chiocchio & Essiembre, 2009). Trust is one parameter of interest in psychosocial studies which could significantly influence performance. Ferrin and Dirks (2003) suggest that trust at both organisational and individual levels is an important element in all working relationships. Working relationships on the other hand impact on projects, because ideal project teams would work towards common objectives for successful project delivery. Thus trust is foundational to relationships (Smyth et al., 2010) and encompasses the behaviours of receptivity, nurturing and caring (Kadefors, 2005).

[1] jrotimi@aut.ac.nz
[2] arqrebcalond@gmail.com

The underlying concept is that trust is needed when risks and uncertainties are apparent and that risks are shared with other parties with an expectation of positive outcomes. Smyth et al (2010) explains that the presence of a trusted party helps to reduce perceived (interpreted or subjective) risks, renders relationships more conducive to risk reduction, and creates organisational and project opportunities to improve process and product. Similarly, Currall and Judge (1995) conceptualized trust as a behaviour that relies on another party under a condition of risk. Accordingly trust consists of two interlinked principles, reliance and risk (Currall and Judge, 1995).

Hannah's (1991) study was able to connect trust and construction project success criteria in terms of participant satisfaction (via the Minnesota Satisfaction Scale) and cost and schedule performance. Taylor et al (1977) also suggests that trust opens the lines of communication, helps self-understanding and the development of interpersonal relationships on projects. However, there are modest empirical studies that examine the nature of blended team working in construction projects without prior working relationships.

Therefore the primary objective of this study is to evaluate the relationship amongst project partners on a construction project and how this impacted on project deliverables. The evaluation was based on the trust model developed by Mayer et al (1995), which consisted of ability, benevolence and integrity, as the main factors perceived to boost trust within blended teams. Ability comprises skills, competencies, and characteristics that enable one party to have influence within some specific area on another. Benevolence implies the perception that a trusted party would have good intentions towards a trustor, aside from any egocentric profit motive. Finally, integrity is a trustor's perception that the trustee will adhere to a set of principles that the trustor finds acceptable. Other secondary or intervening factors that could influence the development of trust in projects include; Boundary Role Persons (BRPs), task conflict, role ambiguity and relationship conflict (Tidd et al., 2004; Simons & Peterson, 2000). However these factors are not analysed in great depth in the paper. Further details on the study approach, data collection and evaluation are provided in later sections.

BRIEF LITERATURE REVIEW

Issues of trust in blended teams on construction projects

Developing trust across blended teams could be difficult, because people frequently perceive individuals from other groups as less trustworthy than members of their own group. In other words, the aspirations, beliefs, or interaction styles of other groups may be seen as a threat to their own group goals (Fiske & Ruscher, 1993). According to O'Reilly et al (as cited in Jehn, 1995), two conflict types are characteristic of inter-organisational groups; task and relationship conflicts. Jehn (1995) explains that task conflicts (or cognitive conflict) derives from a perception of disagreements among group members about the content of decisions and involves differences in viewpoints, ideas, and opinions. Relationship conflict (or emotional conflict) on the other hand derives from a perception of interpersonal incompatibility which typically includes tension, annoyance, and animosity among group members.

It would seem that both types of conflicts between inter-organisations on a construction project are inevitable. Thus conflict is an issue to be expected and managed. Role ambiguity is not uncommon on construction projects, especially where blending for a uniform achievement of project objectives is necessary. Tidd et al (2004) also show that intrapersonal conflict could occur when a goal of an individual

is perceived as frustrated, or about to be frustrated, by another goal of the same individual. Therefore conflicts could arise when there is uncertainty about how one is evaluated, the opportunities for advancement, scope of responsibility, and expectations of others concerning work performance.

Simons and Peterson (2000) have noted that trust is an interpersonal factor that could moderate the link between the task and relationship conflicts. Thus individuals or groups with high levels of trust are less likely to make negative attributions concerning the intent of those engaging in task conflicts. They would respond constructively, accepting stated disagreements at face value rather than as if being attacked (Tidd et al., 2004). Thus empirical researches suggest that the higher the trust the weaker the correlation between task conflict and relationship conflict (Tidd et al., 2004).

To summarise, working in a blended team has inter-organisational benefits. Webber (2008) suggests that working in close proximities with frequent contacts is most likely to enhance interpersonal relationship. Blending operational teams increases the cross exchange of information and with boundary role persons there is every likelihood that trust levels will be appreciable. Although close proximity and mixing teams may be counterproductive in some situations, but largely blending should benefit intergroup and intragroup relationships.

Recognising the complexities of intergroup and intragroup relationships, the current study therefore intends to address questions that border on trusts and its impact within blended teams based on a case study project.

RESEARCH APPROACH

This study investigates the effectiveness of inter-organisational relationships amongst project participants involved in the construction of a NZ$120million industrial facility based in Auckland, New Zealand. Project participants on this case study project were constituted as a blended team made up of the client and a construction management organisation. This was the first time the team would work together to deliver a brown-field project for the expansion of an industrial facility. Staff of both organisations physically shared offices during the two-year (2008-2010) project duration and contributed to the project execution from the conception to the commissioning stages. The blended team configuration led to a unique operational experience, comprising many peculiarities of communication interflow, decision making abilities and trust.

To facilitate the study a conceptual framework was developed and structured around three key themes: ability, benevolence and integrity, the factors of perceived trustworthiness developed by Mayer et al (1995). A semi-structured questionnaire containing four key sections, which included demographic information and questions to cover the ability, benevolence and integrity themes, was administered to 16 senior project members from both the client and construction management organisations.

The questions were largely in the form of scales, rankings and open-ended types to provide clarity to the responses. The data obtained from the questionnaire is presented using simple interpretive and descriptive methods to make the findings communicative and understandable. According to McQueen and Knussen (2002), descriptive statistics are useful for describing, illustrating and summarising information in three ways, forming numbers into tables, generating charts and diagrams from the numbers, and then calculating general statistics. Some thematic correlation of the results was undertaken in order to explain agreements and disagreements in the responses obtained from respondents in the two organisations. In

concluding, the evaluation of the findings were synthesized in order to obtain a clear understanding of the inter-organisational conflicts that impacted on the blended teams' relationships.

A breakdown of the demographic information of the respondents is given in Table 1. Altogether 16 responses are used for the analyses with equal number of responses received from both the client and construction management organisation.

Table 1 – Profile of Respondents

	Electrical Engineers	2
	Mechanical Engineers	2
	TOTAL	**8**

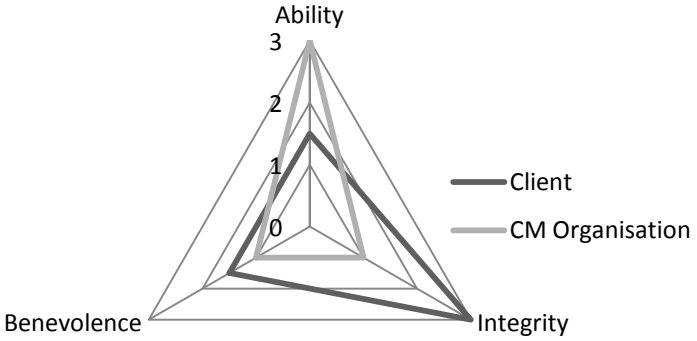
RESULTS AND FINDINGS

Trust between the client and construction management organisations

The three key themes: ability, benevolence and integrity developed by Mayer et al (1995), which are considered to be pivotal to trust between teams were determined from the respondents. Respondents were required to rank the three according to their level of priority, 1 being the least priority and 3 of the highest priority. A simple representation of their responses is depicted in the three-point radar diagram in Figure 1.

Figure 1 – Respondents' perception of ability, integrity and benevolence



On aggregation of the responses, members of the client organisation perceive integrity as the most important to trustworthiness amongst teams. Conversely the construction management team perceived ability as the most important in team relationships.

Members of the client organisation were of the opinion that ability and benevolence were equally important factors for the development of trust following after integrity. Whereas construction management team members considered integrity as the second important factor and benevolence as the least important factor.

The responses seem logical, wherein a client would expect its management company to adhere to certain set of professional rules and principles which would enable the achievement of their project objectives. Therefore the extent to which the construction management organisation actions are congruent with the client's expectations refers to the integrity which was perceived as being pivotal to trust by the client.

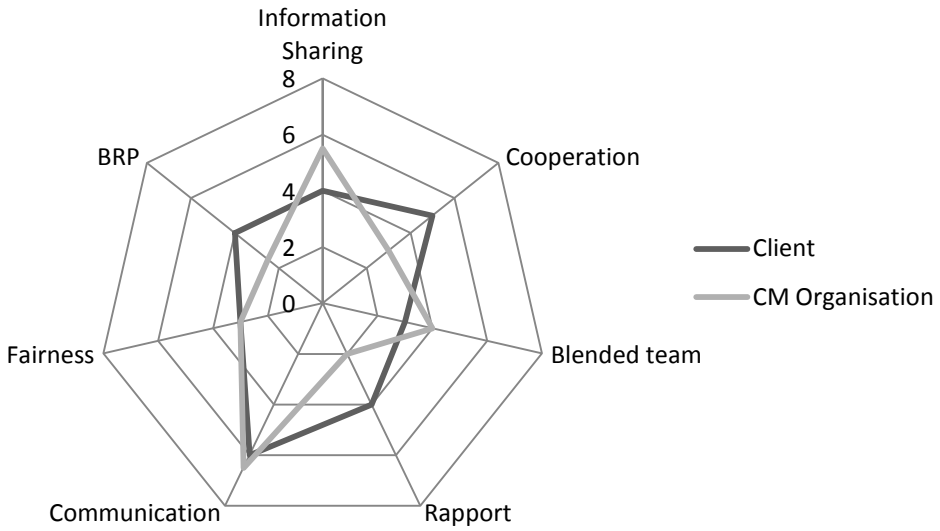
On the other hand, the construction management team members expect the client organisation to possess good level of skills, competences and personal attributes that will enable them work collaboratively in a blended team environment.

Trust development

The respondents were presented with a list of 7 factors that could facilitate the development of trust between them. The aim was to determine the level of importance ascribed to each factor by the two organisation members. Figure 2 gives a diagrammatic representation of the responses.

The findings show that communication was considered the most relevant factor for developing trust by both organisations. This is followed by information sharing and cooperation when all responses are aggregated together. However, cooperation is also an important factor for the client whereas information sharing is more relevant to the construction management company.

Figure 2 – Respondents' perception of trust development factors



Relationship conflict and trust

An aspect of the questionnaire sought to determine to what extent the level of trust is linked to relationship conflicts within these two organisations. The study found that task conflict was experienced by some members of the construction management organisation. Transcripts of two responses from the construction management organisation are included here to explain this. Both statements show that role ambiguity existed in the blended team environment which could lead to relationship conflicts.

My work responsibilities were not clearly defined

My work responsibilities overlap with the client's team responsibilities

Further, transcripts of the responses of two members of the client organisation are provided below.

Yes [relationship conflict exists]. Initial reluctance to include me in correspondence, meetings and discussions during early stages.

My impression was that by incorporating client's member the construction management team felt that we were spying the camp.

On the whole one could deduce positive team development using the blended organisational structure. Two transcripts from the construction management organisation are included in the paper to suggest the blending of the two organisations later on. As may be usual to any brown field project teams it takes time for parties to such projects to develop working relationships that could facilitate trust.

I had no problem working on a blended team. Generally the client's members were older and very senior members and normally specialist in their field. We would act in a supportive role. Often the client's member would say what was needed and we would get it designed and constructed. In similar circumstances I would think to do future projects the same way. [CM team member]

The blended team scenario, in the end, worked well. However, this was imposed over time and was not the original working model for the Contract. If this had been understood from the beginning, a better working relationship between the construction management team and the client's project management team could have been obtained" [CM team member]

Clearly, at the beginning of all projects, it is important that the groups develop and communicate the roles, responsibilities and expectations that they are to deliver. Trust cannot be developed when there is no framework for what role each group plays, so that expectations can be realised. Trust needs to be based on understood responsibilities rather than incorrect perceptions. This is of particular importance in project environments, where trust between team members is vital because many projects have uncertainty, complexity and constant change as daily challenges. Hence mutual trust is imperative. From an effective management point of view, the process of building trust should form part of management objectives.

Power and decision making

Well defined level of power and decision making abilities within a blended team environment should facilitate the interpretation of trust between inter-organisations. Therefore one aspect of the questionnaire addressed the level of power and decision making experienced by both members of the project. Members of the construction management organisation expressed that their level of power or influence was low and that decision making have been taken off them by the client organisation. For example they explain that costs and program decisions were exclusively managed by the client organisation contrary to initial contract terms.

Following these the second sub-question determined the extent that these level of trust links to the need for control and monitoring implemented by the client. The study found that trust levels for the construction management organisation was low hence the client had to implement higher control mechanisms. This situation led to arduous approval processes, closer supervision of construction management activities, and the client requiring frequent communication of results. It was observed by one of the

respondents that the client's involvement in the project (blended team strategy adopted) was a reflection of this poor level of trust.

DISCUSSION

The project was delivered under a traditional procurement system. Most of the work packages were tendered for competitively using familiar service providers with whom the client had long term working relationships (in some cases 20 years). The final contracts were negotiated with the service providers by the client. The original agreement was for the construction management organisation to manage the selection of service providers but this was reneged upon, probably because the construction management organisation had no prior working relationship with the client. There was an allusion of mistrust of the ability and integrity of the construction management organisation to manage the selection process.

The use of a blended team in this project led to a pronounced demarcation of authority and power. For example, key project decisions were made by the client and an arduous approval-supervision process reflected the authority status. Noticeably members of the project team from both the client and construction management organisations experienced role uncertainty, role ambiguity, duplication of work, relationship conflict, time delays and professional frustration. Members of the construction management organisation had indicated that they were constrained to contribute their knowledge and were unable to be more proactive to the project's decision process.

However during the course of the project, the construction management company gained the client's trust and an excellent working relationship was progressively established till the project reached completion. Personnel from the construction Management organisation had acquired the requisite technical skills. These positive benefits were achieved through the implementation of a blended team structure.

The findings demonstrate that trust is pivotal to construction project relationships and is greatly influenced by the level of communication amongst the project parties. All barriers to disclosure had to be taken down to allow trust to develop between these two parties.

CONCLUSION

This study investigated the effectiveness of inter-organisational relationships amongst project participants on the construction of an industrial facility based in New Zealand. The project participants were constituted as a blended team made up of the client and a construction management organisation who were working together for the first time. From the findings it was made apparent that initially there were several trust related issues on the project. But as the project progressed, task conflicts such as disagreements about decisions, and unclear construction management organisation's boundaries were resolved. Therefore the mistrust of the construction management organisation at the inception of the project gradually improved to the point of development of better levels of trust.

The findings are in consonance with various trust theories and models. Trust creates the opportunity for positive working relationships, resulting in improvement to fluent information flow. Supervision and control requirements are eased off since parties to a project could rely on the fact that project requirements will be met through committed performances. Overall trust provides a greater opportunity to achieve successfully managed projects.

Clearly, at the inception of construction projects, it is important that project participants develop and communicate the roles, responsibilities and expectations that they are to deliver. Trust could only develop when there is an operational framework that explains these roles and expectations, so that project deliverables become realizable. Trust therefore needs to be based on understood responsibilities rather than incorrect perceptions.

ORGANISATION CULTURE INFLUENCE ON JOINT VENTURES SUCCESS IN SOUTH AFRICA

Kauzya Siwale[1] and Dr Gerhard Brummer[2]

[1]*Department of Construction Economics, University of Pretoria, Private bag X20 Hatfield, Pretoria 0028, South Africa*

[2]*Davis Langdon, An AECOM Company, PO Box 1642, Houghton, 2041, Johannesburg, South Africa*

ABSTRACT

Joint ventures among quantity surveyors in South Africa are said to be on the increase as organisations seek to be compliant with the Broad based black economic empowerment Act 2003. The Act was introduced with the view of correcting the inequalities of the past. There is a perception that joint ventures are marred with problems. The evaluation of the joint ventures in South Africa with emphasis on organisation culture is the focus of this paper. The study was conducted by analysis of responses from a survey questionnaire sent to the quantity surveying practices through the Association of South African Quantity Surveyors (ASAQS). The results indicate that organisation culture influences the success of joint ventures to a large extent, this finding was critical to the South African construction industry where partners from diverse background and culture have to form joint venture partnerships. The findings also confirmed that joint ventures among quantity surveyors in South Africa were often problematic.

Keywords: Joint ventures, organisation culture.

INTRODUCTION

Organisations find themselves operating in business environments where alliances are the most likely route to guarantee success. This is true in cases where an organisation wishes to enter new areas and then may have to penetrate the new markets quickly before best partners form relationships with competitors. It is also prevalent when entering new markets abroad where local knowledge may be invaluable.

The other advantage of organisations developing alliances is that they may have access to a large pool of resources. Sometimes it is ideal when organisations have different forms of expertise and by sharing a pool of resources they enhance their capabilities and are able to meet their client's expectations.

1. ksiwale@uj.ac.za

2. Gerhard.brummer@davislangdon.co.za

Alliances in some instances dilute the risk for each partner and some stakeholders may prefer this as a way of spreading their financial risk. In the South African context the Broad-Based Black Economic Empowerment Act also called the B-BBEE Act (53/2003) was passed to promote black economic empowerment. The introduction of the Act resulted in an increase in joint venture partnerships among professional quantity surveying practices as they sought to comply with the codes of the Act.

The aims of the study was to determine the extent to which joint ventures are successful in South Africa and also to determine the extent of organisation culture influences on the success of joint venture partnerships.

Joint ventures in South Africa

Organisation culture plays an important role in the relationship of joint venture partners. When different organisations with different cultures developed over years are placed to work in different environments, it may exercise considerable strain on the relationship and subsequently on the success of the project.

Bresnen and Marshall (1999) highlighted cultural alignment as a prerequisite for collaborative working, where organisations shared basic values, attitudes and beliefs and the need for some form of compatibility between organisations. In the absence of compatibility, organisations should change their ways of working. They describe culture as consisting of a system of shared meanings based on common values and beliefs held by members of an organisation.

Elashmawi (1998) outlined some causes of corporate culture clashes as a clash between profit-oriented organisations and socially oriented partners. However, his study points to the executives in multicultural joint ventures being preoccupied with business needs such as raising capital and establishing operational plans but paying less attention to cultural issues that influence the joint ventures day-to-day operations. Yet these are the cardinal issues that can make or break a joint venture operation. The findings of Elashmawi's survey (1998) established that the inability to manage cultural diverse employees leads ultimately to poor performance and reduced revenues.

The South African construction industry, with its historical background of different races and cultures, faces challenges in managing joint ventures, especially if the partners are from diverse backgrounds. Elashmawi (1998) presents a multicultural management process, which could be applied to joint ventures with members who come from diverse professional and cultural backgrounds. The process begins by surveying employees' individual needs during their daily activities. This is followed by seminars, group discussions, presentations and case studies. This would include cross-cultural discussion and team building, where participants point out their strengths and weaknesses. This exercise culminates into participants identifying their core values. The comparisons of the core values help develop action plans to build on corporate strengths and minimise corporate weaknesses. Subsequently, a new culture is created among members. Conflict is overcome through compromise and the implementation of corporate goals that satisfy the multicultural business needs of each joint venture partner. This process is supported by Cheng et al. (2004).

Managing multicultural joint ventures can be challenging. The drivers in the collaboration should understand the intricacies that may be encountered in the day-to-

day operations. Once the structure of the joint ventures is established, a model is developed. Bresnen and Marshall (1999) highlight the potential conflict between commercial pressures and forms of collaboration in practice and the inherent difficulties in attempting to change organisational cultures to support collaborative approaches of working. Al-Khalifa and Peterson (2002) cited compatibility at operational level as the key to the success of the alliances requiring alliance partners to achieve a strong interpersonal relationship that transcends across cultural differences and backgrounds. This is supported by Makino and Beamish (1998), who found that multinational partnerships provide a higher opportunity for superior performance but have a higher likelihood of termination while domestic joint ventures provide a greater opportunity to achieve a superior performance and had a lower likelihood of termination.

The study

Quantitative research design was the most appropriate method to be employed in the study. A questionnaire survey was conducted among professional quantity surveying firms to provide answers to research questions. There are approximately 750 practicing quantity surveying firms registered with the Association of South African Quantity Surveyors which formed the target population. The unit of analysis is, quantity surveying firms. There were a total of fifty (50) respondent firms, registered with the Association. There were no specific geographical requirements all registered firms had an equal chance of being in the sampled group.

The sample population was limited to legally registered firms with email facilities. A non-probability sampling was used to obtain a reasonable sample that would be representative. According to Bartlett, Kotrilik and Huggins, (2001) the minimum sample size required from a population of 750 with a 3% margin of error were 161. However, due to anticipated low responses experienced with questionnaire surveys the sample size was increased to 250 which translated to 55% more than required. The percentage response rate was 20% which was deemed to be adequate. (see table below)

Table .1: The number of questionnaires sent and responses received

Survey responses	**Quantity**
Sampling frame	250
Required sample	161
Questionnaires sent	250
Number received	50
Usable	50
% usable response rate	100

The questionnaire consisted of the 5-point Likert rating scale. The responses would enable the measurement of the intensity of the respondent's perception of the working of joint ventures. The respondents were required to state how they felt about a statement whether they strongly disagreed, disagreed, were neutral, agreed or strongly agreed. Due to restricted space the questionnaire is not included in this article.

 ISBN: 978-1-84219-840-7 .

The responses were then statistically analysed and interpreted, and the findings were outlined based on the data collected. A descriptive statistical approach was used in the analysis and presentation of data. The comments by the respondents were interpreted and the interpretations are provided below each section of the questionnaire. The following statement was analysed and the findings presented in the report:

- The extent to which organisational culture influences the success of a joint venture partnership?

Conclusions were drawn from the findings and recommendations were made in order to answer the research questions.

The survey results indicate that 52% of the respondents stated that organisational culture was a major cause of problems in a joint venture, 21% disagreed, while 27% were neutral. On the question of organisation culture influence the survey results indicate that 88% of the respondents agreed that organisational culture influenced the success of joint ventures, 4% disagreed and 8% were neutral.(see figure 2)

Figure 1: Organisational culture

 ISBN: 978-1-84219-840-7 .

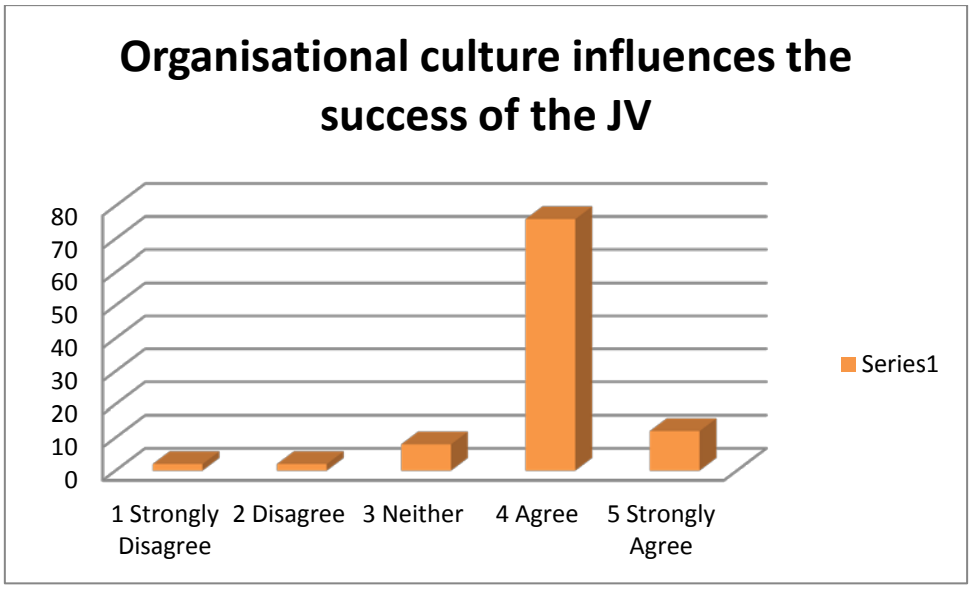

Figure 2: Organisational culture influences the success of a joint venture

On the application of multicultural management process applied in joint ventures when partners come from different cultural backgrounds. The results of the survey indicate that 46% of the respondents agreed that a multicultural management process should be applied in joint ventures when cultural issues arose, 14% disagreed and 40% were neutral. The respondents also agreed that cultural alignment should be a prerequisite for joint ventures. It was also found that executives paid much attention to cultural issues that influence day-to-day operations of a joint venture. These findings are very important since South Africa is composed of people from diverse backgrounds, which could adversely affect the working and success of a joint venture. The respondents agreed that the aspect of race and cultural background could not be ignored in a joint venture working environment in South Africa. The results indicate that 46% advocated the use of a multicultural management process when dealing with partners from different backgrounds. The findings fully support the earlier study by Bresnen and Marshall (2000). Bresnen and Marshall (2000) stated that cultural alignment should be a prerequisite for joint ventures where organisations share basic values, attitudes and beliefs and there should be compatibility between organisations, sometimes referred to as partner fit. It is interesting that the study points to compatibility as a key factor. In the same study, when reviewing the results of partner selection and rankings of key factors, the findings for the South African construction industry indicate that compatibility was the most important factor in partner selection and the results indicate that 90% of the respondents indicated compatibility as a key factor.

 ISBN: 978-1-84219-840-7 .

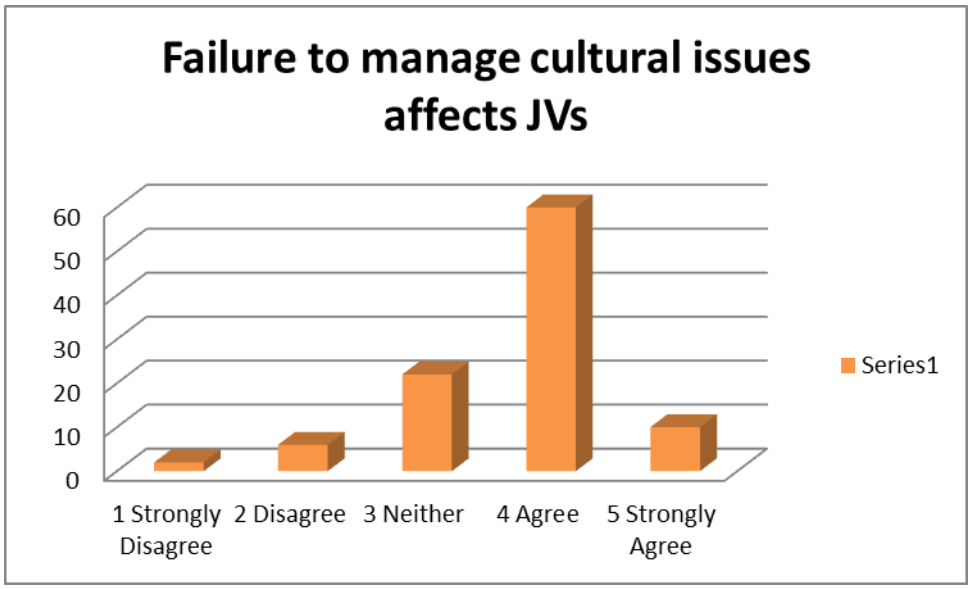

Figure 3: Failure to manage cultural issues affects joint ventures

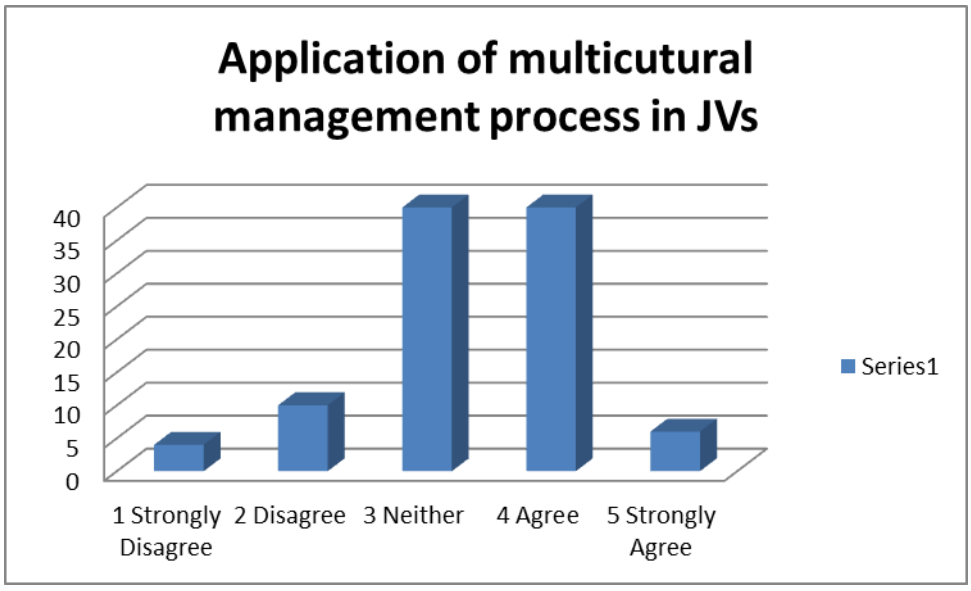

Figure 4: Application of multicultural management process in joint ventures

The findings indicate that to a large extent, organisational culture influenced the success of joint ventures, though less than half advocated the use of a multicultural management process to deal with matters of cultural difference. The results support the statement that organisational culture can influence the performance of a joint venture. The findings also support the research question on whether joint ventures were marred by problems.

CONCLUSION

The study results indicate that although problems were encountered, the partners in a joint venture were focused on delivering a product for the client. Compatibility was seen as a critical factor for consideration in joint ventures. Organisational culture was seen as an important factor that could adversely affect the joint venture relationship. The survey highlighted the major causes of problems and organisation culture. Careful evaluation of culture differences should be undertaken. It is recommended that further research is conducted on the development of a model that can be used for evaluating a culture differences in an organisation.

RECOMMENDATION

Upon establishing that there are organisational cultural differences, the partners should identify ways of working together with diverse views, beliefs and objectives. This can be achieved by the use of workshops and team-building exercises prior to commencing the joint venture activities.

OVERCOMING THE BARRIERS TO INNOVATION IN PPP/PFI PROJECT-BASED ENVIRONMENTS

Ndoni, Doubra Henry[1] and Elhag, Taha[2]

[1,2]*Bartlett School of Construction and Project Management, University College London, UCL, WC1E 7HB United Kingdom*

ABSTRACT

The mainstream literature of the concept of innovation is vast. So far the discussion on innovation has presented views from multiple disciplinary backgrounds of which it can be complementary to improve the understanding of innovation and it can as well lead to more confusion. Innovation in project-based organisations is a major challenge especially in PPP/PFI projects. The main barriers identified in the literature are: a) the one-off nature of projects; b) the configuration of construction work; c) lack of joint collaboration; and d) the challenge of managing innovation. One important aspect of the innovation process is the need for the innovating system to gather information and transmit same to several external information areas across organisational boundaries. But, there is paucity of research that has demonstrated how project-based organisations can influence innovation in construction projects. This is the main challenge of this research to examine empirically the factors that support innovation and to understand how project-based organisations innovate. So that project managers and decision-makers can relate to in order to encourage sustainable innovation in projects marks the point of departure of this research work. To achieve this objective a questionnaire survey was designed and distributed among PPP/PFI practitioners in the United Kingdom based on the likely factors identified in the literature to influence PPP/PFI innovation. Also, three case studies were examined. The findings are evenly replicated and it suggests that to influence innovation in project-based environments: a) interpersonal ties formed are very important; b) networks of learning; c) network governance; d) organisational capabilities; and e) joint collaboration between clients, suppliers, manufacturers and researchers are very crucial. The findings have considerable significance to construction practitioners and managers on how to overcome the barriers to innovation.

Keywords: Collaborative networks, Innovation, Project-based organisation, PPP/PFI.

INTRODUCTION

It is without a doubt that the UK construction industry is suffering its worst recession for 100 years of which banks have virtually stopped lending to construction companies and this have impacted on delaying vital payments on projects (Harding, 2010). However, it is well documented that the integration of innovative approaches in construction projects is a better way to improve the construction industry performance (Egan, 1998). Although, improvements have been achieved after the

[1] d.ndoni@ucl.ac.uk
[2] t.elhag@ucl.ac.uk

Egan report, but there is still shortfall in practice as the 30 per cent target in project savings has yet to materialise (Smyth and Olayinka, 2010).

It then suggests that more research is needed to improve understanding of how to stimulate innovation within established construction methods and processes to improve project performance. The starting point is for the organisation to: a) identify the need for the innovation; b) to establish and maintain effective and efficient innovation process; and c) to provide or acquire the related resources to enable its implementation and application (BSI, 2009). Innovation should not only focus on reducing cost, time and to improve quality but also on achieving a low-carbon future through the use of sustainable building materials. Nevertheless, the temporary and unique nature of project-based organisations can pose a hindrance for the integration of innovation in projects been delivered.

Furthermore, the discussion on innovation has presented views from multiple disciplinary backgrounds which can be complementary to improve the understanding of innovation and can as well lead to more confusion. In a similar vein, Galanakis (2006) noted that several theories have been developed on how innovation occurs in an organisation and which factors affect the outcomes of this process. But, argued that these theories come from different perspectives that focus on management, economics or social sciences and create a complex net that makes managers take decision that the outcome of which contradicts their original objectives. Overall, the literature on project-based innovation in construction is limited. The main challenge of this paper is to investigate empirically the factors that support innovation although varied initiatives to stimulate innovation have been identified in the project-based innovation literature; project-based organisations are limited by the short term focus of participating organisations to initiate or stimulate innovation.

KEY ISSUES IN THE INNOVATION PROJECT-BASED LITERATURE

In the construction literature, Thomas and Bone (2000) identified three key areas for innovation activity that "can deliver significantly improved quality and value as: a) supply chain management and partnering; b) value and risk management; and c) technical innovation (p.67). Based on a substantial literature review of project-based innovation, Keegan and Turner (2002) found that the strict over-reliance on project control and evaluation methods often appears to suppress innovation. Furthermore, innovation is seen to be risky, costly and often dangerous to implement. On the other hand, Gann and Salter (2000) had earlier argued that project-based organisations are only able to harness and reproduce their technological capabilities when they integrate or link non-routine project processes and routine business processes.

But, Acha et al., (2005) argued that the challenge several project-based organisations face is how to manage the interaction between temporary actions and repetitive business practices such as innovation that provide the means in which projects can thrive. Therefore, it suggests that innovation in project-based organisations is more becoming episodic in nature. For this reason, there is a strong need for project-based organisations to stimulate innovative ways to improve their project performance.

On the other hand, to significantly encourage innovation, Blindenbach-Driessen and van den Ende, (2006) found that the success factors for functionally organised firms, as described in the literature seem to be more important in project-based firms but others appear redundant. For example, the application of contingent planning

approaches and the availability of sufficient experts. But the use of cross-functional teams, experienced project managers, and cooperation with customers, suppliers and market researchers are important in project-based innovation process.

But, the view of Whitley, (2006) suggest that project-based organisations differ considerably in a number of ways, particularly the singularity of their goals and outputs and the distinctiveness and stability of work roles and task organisation. It implies that the temporary nature of project-based organisations obstructs the possible development of any distinctive organisational or technical competencies to improve future project performance. To practically influence innovation, collaborative learning and knowledge creation are significant ingredients to sustain creativity for competitiveness (Nonaka, 1994). The challenge for project-based organisations is how to identify organisations with requisite capabilities and knowledge to collaborate with to create valuable products.

Nevertheless, Aouad et al., (2010) discover that innovation, whether at an international, national, regional, firm or project level of analysis, continues to be at the forefront of the mind of policy makers and practitioners alike. Yet, their understanding of innovation is far from complete. They also suggested that more research is required to study innovation at these different levels of resolution and at different points in the project life cycle. In order for the research base to play its part in promoting construction innovation, an engagement mechanism is required that brings together academia and industry in a way that recognises and responds to these multiple perspectives on innovation.

Overall, innovation is found fundamental to improve the performance of the construction industry, but understanding innovation process, how innovation can be enhanced and how it can be measured are key stages to facilitate innovation (Gambatese and Hallowell, 2011). Hence, it is imperative to identify the significant factors that can enable innovation within project-based environments. This study builds on previous studies conclusions on the barriers of innovation, which suggested that the discontinuous nature of project-based production and the configurations of construction work, with divisions between disciplines and organisations is a major obstruction to attempts to initiate new innovations and initiatives within project-based environments (Gann and Salter, 2000; Harty, 2005). However, the literature identified a number of means to stimulate innovation within project-based environments such as: a) technical support of construction practitioners' such as providing training can be a useful means to stimulate creativity (Eaton et al., 2006); b) capabilities need to be accumulated from project-to-project (Bayer and Gann, 2007). The construction literature similarly identified several factors to deliver innovation in construction organisations. The study conducted by Miozzo and Dewick (2002) suggested that inter-organisational cooperation can be a useful means to improve construction innovation. Furthermore, subsequent studies suggested that construction innovation process depends on how knowledge management activities are integrated (Manley, 2008) to stimulate innovation. Nevertheless, the longetivity of projects been delievered by project-based organisations is a key impediment to the recommendations researchers present on how to initiate innovation. Therefore, most academic papers provide little on how to effectively overcome the barriers to innovation within project-based environments. In addressing this concern, there is a strong need for construction and project management practitoners to continuously advocate inter-organisational collaboration for knowledge transformation to improve construction processes.

RESEARCH METHODOLOGY

The main objective of this paper is to identify the appropriate means to successfully stimulate innovation from the perspective of PPP/PFI practitioners working within the PPP/PFI framework in the United Kingdom. Through this approach, the research sought what factors are suggested by practitioners and how the factors can play a significant role to sustain continuous innovation in construction. To achieve this objective, the research used a structured approach in administering questionnaires and case studies on-going projects. The quantitative data provides insight into the views of PFI practitioners involved in on-going PFI projects on critical factors that support innovation and then qualitative data was necessary in order to confirm the factors. Interviews were used to gather information/data on key factors that stimulate construction innovation.

The main project partners were interviewed. These are: a) project clients, b) construction firms and c) project financiers. Interviewees are working for three separate consortiums formed to deliver three different Building School for the Future schemes in the United Kingdom. Overall, seven people were interviewed and the questions are semi-structured. These interviews took approximately one hour for each interviewee. Also, a total of 200 questionnaires were distributed to both public and private organisations representing organisations known to be involved in PFI projects via e-mail and postal mail. A total of 66 completed questionnaires were returned giving a response rate of 33 per cent. Factor analysis technique was chosen as a means to achieve the paper's objective with the help of Statistical Package for Social Software (SPSS), to capture cluster of relationships within a number of variables.

RESEARCH RESULT

The paper identified thirteen (13) essential factors to stimulate project-based innovation. Table 1 shows the ratings of PPP/PFI practitioners on the factors to significantly stimulate innovation within PPP/PFI project-based environment. Table 2 shows the factor loading after rotation. Factor loadings with an absolute value greater than 0.5 was interpreted and Kaiser-Meyer-Olkin measure verified the sampling adequacy for the analysis, KMO = 0.763 and the values of MSA are reasonably high; this ranged between 0.672 - 0.870 except for one variable that is 0.323, apart from that variable the variables are well above the acceptable limit of 0.5 (Field, 2009). Bartlett's test of sphericity x^2 (78) = 359.862, $p < .00001$, indicated that correlations between items were sufficiently large for factor analysis.

Table 1 PPP/PFI practitioners' views of enablers of innovation in PPP/PFI projects

Factors	Private Sector respondents Severity Index	Public sector respondents Severity Index	Category Ranking (Private Sector)	Category Ranking (Public Sector)
Interpersonal and informal networks of learning	73.33%	81.94%	8	6
Formal exchange of knowledge	72.35%	77.78%	9	8
Informal exchange of knowledge	75.61%	76.39%	6	9.5
Joint working team	86.18%	86.11%	2	1.5
Decision making process	79.67%	86.11%	4	1.5
Joint governance structure	61.67%	76.39%	12	9.5
Relevant human resource expertise	73.98%	79.17%	7	7
Incentive policies	64.23%	63.89%	11	13
Diffusion pattern of new idea	61.40%	71.01%	13	12
Trust	88.03%	86.11%	1	1.5
The degree of connectedness between partners	82.50%	83.33%	3	5
Strength of individual, firm and network direct ties maintained	76.67%	76.39%	5	9.5
Strength of individual, firm and network indirect ties maintained	71.05%	72.46%	10	11

Table 2 Rotated Factor Matrix for factors to stimulate innovation within project-based environment
CASE STUDIES ANALYSIS

Factor label	Influential Factors	Code	Factor loading
Factor 1: Interpersonal ties	• Strength of individual, firm, and network direct ties maintained	ToPromIn3L	0.941
	• Strength of individual, firm, and network indirect ties maintained	ToPromIn3M	0.735

Factor 4: Network governance	• Joint governance structure	ToPromIn3f	0.970

Interpreting Patton (2002, p.244), 'there are no rules for sample size in qualitative inquiry it depends on what you want to know, what will be useful, what will have credibility, and what can be done with available time and resources'. The case studies analysis on approaches to overcome barriers to innovation is focused on three BSF schemes: a) Leeds, b) Manchester and c) Blackburn with Darwen. To understand how project-based organisations innovate. The interviews conducted provided some interesting details. First and foremost, organisational capabilities were found to be very significant in any innovation process by the project-based partners.

In this paper, organisational capabilities refer to having the right people with the right knowledge. In order to improve the operational performance of the schools, the project client at Blackburn with Darwen BSF scheme points out that the brief for all the schools projects as a priority the design quality most achieve life sustainability to reduce maintenance cost. However, the project client explained that the standard LEP construction supply chain model may limit innovation because of the processes that are imposed. In a similar vein, one of the project partners at Leeds BSF identified the rigidity of the BSF framework as one of the factors that hinders innovativeness.

Second, one of the interviewees at Leeds BSF highlighted that a number of Head Teachers and Local Education Authorities do not want buildings that are absolutely new and untested. However, the led construction organisation at Leeds BSF scheme was of the opinion that within project-based environments innovation comes when the whole project partners have sufficient time and the scope of the innovation is affordable. Third, also the BSF project client at Manchester believed that innovation in building products is very slow in the United Kingdom but so far most of the innovations are for products that are very expensive and the payback period are very long.

It is clear that still a lot of work has to be done to effectively stimulate construction innovation within project-based environments; it is not surprising that there is growing need for new approaches and concepts to practically integrate innovation within projects delivered by construction organisations. Since, it is expected that the integration of innovation can enhance project performance. To achieve this will require different organisational capabilities.

Overall, the identified major innovations found in the BSF schemes investigated are process innovation such as standardisation of specification and new projects approval process aligned with (Royal Institute of British Architects (RIBA). On the other hand, innovation that has to do with new product development was less visible in the schemes. It then suggests that PPP/PFI project-based organisations struggle with the issue of innovation. However, it is important to note that the projects investigated: a) Leeds, b) Manchester and c) Blackburn with Darwen BSF schemes are judged to have performed well in the schools delivered. All the respondents suggested that: a) innovation is stimulated when you have the respective project-based teams' collectively working together; b) forums to enable the generation and transformation of knowledge and c) human and resource capabilities to stimulate innovation to create value.

DISCUSSION OF FINDINGS

Findings from the questionnaire survey and views summarized in this paper raise discussions about how to overcome the barriers to innovation within project-based environments. Previous studies have suggested that to stimulate product or process

innovation it is crucial that collaborative relationships are maintained (Reichstein et al., 2008). In a similar vein, the study by Eaton et al., (2006) strongly suggested that collaborative relationships with the external environment are important to access information and appropriate facilities. Also, the study by Miozzo and Dewick (2004) was able to demonstrate the significance of inter-organisational networks to stimulate innovation. A missing link in most studies is how to stimulate innovation and what factors are significant in the innovation process. This is the contribution of this paper.

The interpretation of the results provides potential answers. From both studies conducted, a) maintaining interpersonal ties with research institutions, clients and manufacturers b) advocating long-term collaborative relationship; c) networks of learning to provide means to gather and transform knowledge and d) network governance to provide means to control and manage the networks relationships are identified as appropriate means to support innovation. The practical implication here for project-based organisations is that when they embed themselves in collaborative networks it increases their access to new knowledge and provides a means for learning to improve their projects. The BSF schemes investigated demonstrated that collaborative relationships that are long-term focus provide better means to initiate innovative approaches within project-based environments. The standardization of building products and the new programme approval process are examples. Also, the findings of this research suggest that PPP/PFI project-based organisations are no different from other project-based organisations regardless of the project structure.

CONCLUSION AND IMPLICATIONS

Based upon the research results, we have described and identified how project-based organisations can stimulate construction innovation. The paper has demonstrated that project-based organisations working within project-based environments struggle to initiate product innovation as the short-term focus of participating organisations and the working contractual frameworks with which they use hinder their drive to innovate. It is worth emphasizing that if project-based organisations establish and develop collaborative networks their collective project knowledge can be gathered to create valuable products which can be used to improve their subsequent projects. The network can serve as a learning hub for the creation of new ideas. The practical implication for project managers and construction practitioners is that the network approach provides a significant means to enhance their creativity through knowledge sharing leading to the building of organisational capabilities.

PITFALLS IN OUTPUT SPECIFICATIONS FOR PUBLIC PRIVATE PARTNERSHIP PROJECTS AND THEIR SOLUTIONS

ARSHAD ALI JAVED[1], PATRICK T.I. LAM[1], ALBERT P.C. CHAN[1]

[1] *Dept of Building & Real Estate, The Hong Kong Polytechnic University, Hong Kong SAR, China*

ABSTRACT

Public Private Partnerships (PPP) has grown very rapidly in the last couple of decades for the procurement of infrastructure and municipal services. These services are procured using output specifications, which stipulate the output-based requirements of clients and also cover issues such as physical asset, facilities, level of service, change mechanism, performance criteria linking payment mechanism and risk allocation. Output specifications are considered an integral part of contract documents for PPP projects but pitfalls abound in the drafting of output specifications. Well designed and structured output specifications not only provide an opportunity to the private sector to offer innovative and cost effective solutions to the client but can also minimize future conflicts arising from PPP contracts. Value for money can only be achieved with careful drafting and enforcement of output specifications. An examination was undertaken on the roles of output specifications in the PPP process, together with their features and common pitfalls, through a study of examples. Solutions were recommended to avoid the pitfalls.

Key Words: PPP/PFI, output specifications, pitfalls, solutions, change management.

INTRODUCTION

Public-private partnerships (PPPs) have attracted wide interest around the world (O'Flynn and Wanna 2008) and have grown rapidly in the last couple of decades (Doloi and Jin 2007; Regan et al. 2011). PPPs have been used in more than 85 countries around the world for procuring social and economic infrastructure projects (Regan et al. 2009). PPP procurement strategy is still expected to be a major procurement route in the foreseeable future (RICS 2011). One of the prime motives of governments launching PPP projects is to shift the life cycle risk to the private sector (Chan et al. 2010) while achieving value for money through effective and robust output specifications (KPMG 2010). PPP contracts are based on an output specification approach and an output specification is considered an integral part of the bidding documents for PPP projects (Department of the Environment and Local Government 2000). The output specifications articulate the public sector client's required standards of services whilst the private sector chooses how to meet and possibly improve upon these standards (Iossa et al. 2007). They also delineate

responsibilities (as a means of risk allocation) between the public sector client and private sector operator (Lam 2007). A well drafted output specification is fundamental to developing a robust PPP/PFI contract and the successful delivery of long term asset and services (4Ps 2005; Sanders and Lipson 2001).

The main advantage of PPPs is to deliver value-for-money, which takes some efforts to achieve and the most important value-for-money drivers are the transfer of risk, the output-based specifications, the long term nature of contracts, the performance measure, the increased competition and the private sector management (van Herpen 2002). However, experience has shown that they may sometimes go wrong resulting in failures for PPP projects which have happened around the world and in some cases it was because of shortfalls in specifications or unclear contractual obligations and poorly designed contracts (Iossa et al. 2007). For example, there have been instances where contractual deductions for poor performance were insufficient to make the private sector agile (e.g. the London Underground case), or where the contract omitted to specify what should be conditions of the facility before the contract expired (Iossa et al. 2007). Due to the long term nature of most PPP contracts, mistakes at the initial contract drafting stage can lead to very high cost for the public sector client (Iossa et al. 2007). In this paper, the features, prospects and pitfalls of output specifications for PPP/PFI projects are discussed, focusing on the impact of these pitfalls on the performance of PPP projects. Of particular interest are the various problems related to the development of output specifications. Solutions are proposed to avoid possible problems in the project life cycle by careful drafting of output specifications for PPP/PFI projects.

OUTPUT SPECIFICATION FEATURES

Output specifications stipulate *what* services are to be delivered rather than *how* they should be delivered in order to maximize the opportunity for innovation from the private sector contractor (Cartlidge 2006; Infrastructure Australia 2008). Akintoye and Beck (2009) argued that good output specification clearly states the client's requirements and reduce the possibility of disputes in the later operational phase of PPP/PFI projects. Writing a clear and effective output specification is a very difficult and skillful job (Lam et al. 2010). McDowall (1999) opined that the output specification has changed the attitude of specifying building and service requirements, concentrating on the performance aspects which are important to clients. Output specifications contain aspirations, aims, objectives, purpose, scope, performance requirements, and also address standards of compliance, constraints, risk allocation, hand-back requirements, etc. and encourage alternative or innovative solutions (HM Treasury 1998). Payment mechanism is also an essential part of PPP projects and is linked to the performance standards to be achieved by the private sector. Performance standards are necessary for ensuring the delivery of outputs to client's requirements. Some particular performance standards may not be easy to define in output terms; a technique of *equivalence* can be adopted (HM Treasury 2003). To monitor these performance standards, the client specifies key performance indicators (KPIs). Some of the KPIs may be onerous to achieve by the contractor. The following Figure 1 shows the relationships between service requirements set out in the output specifications, the performance framework, the payment mechanism, and the contract monitoring regime.

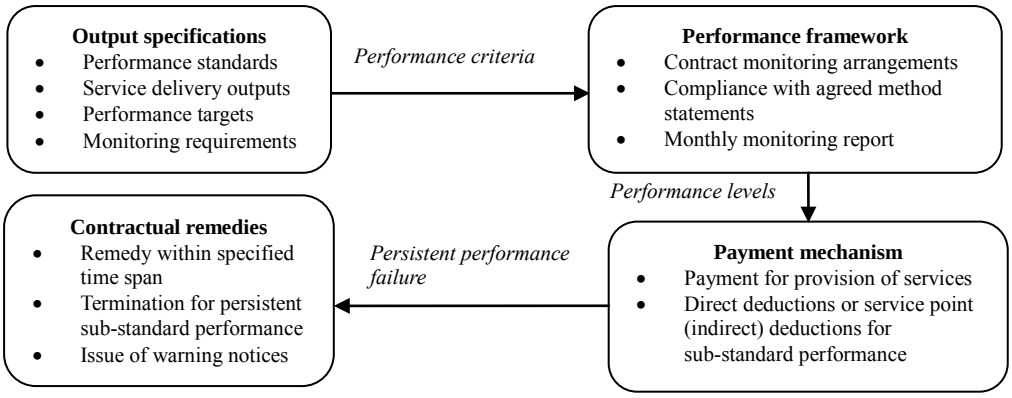

Figure 1 Relationship between output specifications, the performance framework, the payment mechanism and contractual monitoring system (Source: adapted from 4Ps 2007).

Figure 2 shows that the most frequent reason for disputes in PFI projects as surveyed in the UK is over interpretation of contracts and the second frequent reason is poor performance, quality of service and output specifications.

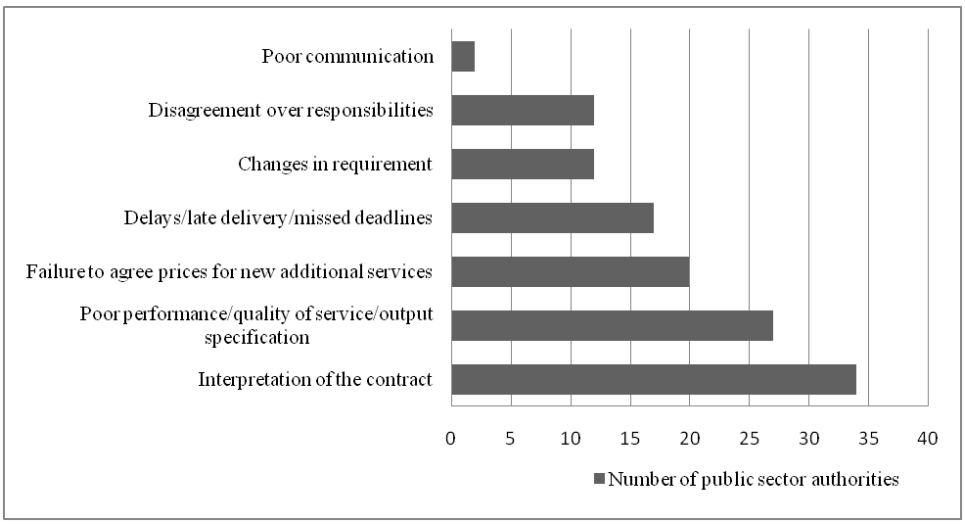

Figure 2 Main reasons for disputes in UK's PFI projects (Source: National Audit Office 2001).

Changes in client's requirements and legislation/regulations also affect PPP/PFI projects. In school and hospital PPP/PFI projects, core services are not part of output specifications (e.g., clinical services, teaching/education services are provided by the public sector) and if there would be any change in the core requirements it can ultimately affect the facilities management services specified in the output specification (Robinson and Scott 2009). Negotiations for large changes after financial close are rather difficult to achieve because the lenders need to be involved (Edward et al. 2004; Partnerships UK 2006).

POTENTIAL PITFALLS IN OUTPUT SPECIFICATIONS AND THEIR SOLUTIONS

Although standard output specifications are being developed and used in mature PPP markets such as the UK and Australia, not much literature addressed potential pitfalls in output specifications and provides solutions on problems arising. There is still a great deal to learn from the pitfalls inherent in output specifications. Due to the long term nature of PPP concessions, the user requirements evolve over time and there is a

risk that the output specifications agreed in the initial contract stage become inadequate because of changes in technology, policy and society preferences, etc. (Iossa et al. 2007). The parties involved are bound for a period of 20-30 years which also reduces flexibility (Alexandersson and Hultén 2007). This lock-in situation may sometimes be exploited tactically by the private counterparts for renegotiations (Hoff 1994; Williamson 1983). The common legal term '*fitness for intended purpose*' seems to be very comprehensive, but can be misinterpreted by the private sector contractor. The fitness for purpose of the project should be aligned with the client's mission statement and the facilities must be appropriately maintained by the private sector and where necessary upgraded to ensure that it continues to be fit for its intended purposes throughout the concession period (Chew et al. 2005).

To cater for future changes in the user requirements, flexibility should be made in the output specifications (Addleshaw et al. 2006). It was found in an inquiry into contractor's performance that a major reason for user dissatisfaction with a number of PFI school refurbishment projects was its output specifications. A spokesman for the Public Private Partnership Programmes (4Ps) pointed out that there was a gap between user expectations of what the output specifications would deliver in terms of quality and what was actually delivered. It was concluded that *"the output specification be replaced with clear input specification in all schools PFI refurbishment projects in the future"*. Most contractors prefer the use of input specifications because everyone will know exactly what is expected and what to deliver (Carol 2003), apart from the retention of design liability by the specifiers. In the case of cleaning in hospitals, it is difficult to describe outputs in contractually effective ways, which are consequently difficult to monitor (Edward et al. 2004). Examples of potential problems of output specifications and their solutions as extracted from the literature are shown in Table 1.

Table 1 Examples of pitfalls and their solutions for output specifications of PPP/PFI contracts

Possible problems	Proposed solutions
• Client unclear about the vision, scope, objectives, aspiration and requirements. • Client's objectives may conflict with each other. • Subjectivity of output specs which permits different interpretations of acceptable standards such as disagreement over the meaning of *clean* is often vague. • Miss-interpretations and different interpretations of contract documents. • Output specs often repeated the following subjective terms (Radford, 2001): - *minimum mechanical ventilation for the building;* - *minimum solar gain to avoid air conditioning/cooling;* - *maximize daylight;* - *sympathetic to surrounding buildings, etc.*	• Client requirements to be adequately defined. • Clear communication of vision, objectives, aspiration and client's requirements. • Enable innovation and cost effective solutions (Ministry of Finance 2004). • Clear, concise and comprehensive output specifications can delineate responsibility and minimize ambiguity. • Objective criteria should be used for performance monitoring. • Subjectivity should be kept to the minimum level. • A clear understanding of what is required and how it is to be monitored. • *Watch out for disputes* over interpretation and subjectivity. • Output specs should not be too prescriptive nor too brief.

• Affordability can create problems in the preparation of output specifications because the government has financial constraints and other financial commitments (Heavisides and Price, 2001). • The public sector may have to sacrifice some user requirements due to affordability constraints after entering into contract.	• Financial planning at the early stage of outline business case (OBC). • Striking a balance between the required services and available funding. • The public sector should not over-specify in excess of the limited budget.
• Unclear risk transfers if the public sector fails to transfer the risk to the private sector. • The public sector fails to quantify the operational risk including volume risk, availability, performance, maintenance, lifecycle, legislation and technology risks, etc.	• Clearly define exclusions of responsibilities. • Appropriate risk allocation to the party best able to manage them to achieve value-for-money objective. • Mutually acceptable risk allocation scheme should be adopted before the contract is awarded (Li et al, 2005). • Clear statement of third party revenue sharing.
• Using input based services specifications • Monitoring problems due to the mixing of input and output specifications (Edward et al. 2004).	• Avoid specifying input such as how to build facilities and how to design the work process but focus should be given to the output-based specifications, instead of input requirements. • Hybrid specifications may be used with care to avoid contradiction (Heavisides and Price, 2001).
• Miss-interpretations and different interpretations of contract documents.	• A clear understanding of what is required and how it is to be monitored, with clients confirming method statements submitted by contractors before contract signing.
• Change mechanism and re-negotiation problems. Change mechanism in the contract is considered as cumbersome and laborious (Partnerships UK, 2006). • Client's requirements may well change in response to shifts in technology, social expectations, and/or policy. • Changes in service requirements can lead to extra time and cost.	• Changes are inevitable and should be envisaged at the initial output specs drafting stage. • Foreseeable changes need to be addressed by pre-agreed framework to facilitate negotiation.
• Inflexible and rigid long term contracts.	• Flexible PPP contracts can allow variations in specification and requirements with appropriate an adjustment mechanism for payment to the private sector.
• Problems with performance measurement system (PMS). • Complex and a large number of key performance indicators (KPIs) and lack of clear understanding among the public and private sector staff (Robinson and Scott, 2009). • Too many and onerous KPIs are not easy to measure. • PMS is not rigorous enough. User satisfaction survey is not linked to the payment mechanism (Akintoye and Beck 2009).	• Clear performance standards and clear understanding of how performance will be measured and monitored. • A clear link should be made between payment mechanism with agreed standards and KPIs (Ministry of Finance 2004). • PMS should be *objectives, transparent*, *easy to measure* and *the same monitoring methods* should be used including customer surveys, performance and fault reporting system. • Establishing the right monitoring method against the required standard is very crucial for the public sector client and ensuring that justifiable deductions are made (Ministry of Finance 2004; Robinson and Scott 2009).
• Payment and performance mechanism may be complex and punitive and do not incentivize for over-performance (Partnerships UK 2006). • Payment mechanism does not incentivize the service provider to deliver higher services than stipulated in the contract. The service provider focuses to avoid performance	• Performance based payment mechanism is necessary to include incentive and deductions for failure of services. • Deductions should *reflect the severity of failure.* • Indexation, benchmarking and market testing are used to minimize the risk of inflation.

deductions rather than getting incentive for higher performance (Robinson and Scott, 2009).

- The assets may not be handed over to the public sector client in a good working condition and are not fit for its intended purpose after expiry of the contract.
- In the contract, the public agency should also specify the state of the assets at contract expiry and it should ensure that the assets are in reasonable working condition and fit for purpose at the end of the contract.

CONCLUSION

In order to achieve value for money, efficiency, innovative solution and risk transfer from the public to the private sector, clients' requirements can be written as service output specifications rather than as prescriptive specifications. A clear delineation of responsibilities is also an essential attribute of output specifications for ensuring appropriate risk allocation. Public sector clients need to devise effective performance monitoring tools. Output specifications should detail *what* needs to be achieved, not *how* it is to be achieved. Output specifications which lack clarity often cause disputes and can adversely affect the value-for-money of PPP/PFI contracts. It has been learnt that there are grey areas in the output specifications, performance measurement system and payment mechanism. There is a need to mitigate these deficiencies by writing outputs as objectively as possible and the public sector should not over-specify, keeping in mind the affordability constraints. PPP projects should deliver innovation, achieve value-for-money through whole lifecycle costing approach and maintain balance between affordability and user requirements. The public sector should ensure that the defined outputs are met by the service provider and also ensure that risk allocation, payment of the unitary charge, reporting and variations to the contract are effectively managed. Learning from previous projects can avoid future pitfalls in developing output-based specifications.

PPPS FOR TRANSITIONAL ECONOMIES: SOUTH AFRICAN CASE STUDY

Nthatisi Khatleli[1]

[1]*Post Doctoral Research Fellow, University of the Witwatersrand, School of Construction Economics and Management, 1 Jan Smuts Avenue, PO Box 20, Braamfontein, Johannesburg, South Africa.*

ABSTRACT

Most countries in Africa have recognized that economic transition does not necessarily mean moving from a state-controlled to a liberalized economy. This is demonstrated by attempts to extricate themselves from economic climate dominated by patrimonial and/or patron-client relationships to a western inclined rules-based system. The compromised environment affects the efficiency and effectiveness of any procurement method in achieving socio-economic objectives.

The profound political change in South Africa within an already existent free-market economy has resulted in economic transition, as the formerly disenfranchised black people seek meaningful economic participation. Through the policy of Black Economic Empowerment (BEE), the new democratic government has tried to use procurement as a tool to effect change and PPPs in particular have been identified as being critical in achieving economic emancipation. This research tracks one of the longest running PPPs in South Africa to assess if there is any alignment with government's socio-economic interests.

This research has demonstrated a substantial goal alignment catalyzed by PPPs peculiarities of longevity and protracted tender processes among others. It is hoped lessons learned in this research will not only help in streamlining legislation for future projects, but could also be of immense benefit to other pre-transitional and transitional economies in Africa and elsewhere.

Keywords: Black Economic Empowerment (BEE), Public Private Partnerships (PPPs), Transitional Economy,

INTRODUCTION

The economic transition in developing countries has not always been the result of a change from a centrally-controlled to a free-market economy. Transition does happen in an already existent free-market economic activity, when change is triggered by momentous political incident, as was the case in South Africa (Cameron, 2003). The release from prison of the ANC leader Nelson Mandela in 1990 was not just a political milestone, but it had repercussions to the social and economic life of about 30 million non-white South Africans who were previously disenfranchised (ibid). Elsewhere in Africa although there are very poor countries which can be labelled pre-transition, some countries have been transitioning as they divorce themselves from

[1] nthatisi.khatleli@wits.ac.za

previously socialist inspired policies and embrace free enterprise (Mckinsey Global Institute, 2010). The 'traditionally acknowledged' transition economies of the former Soviet Union, Central and Eastern Europe, China and Vietnam, were similar in that their planned economies had been dominated by large firms, producing few consumer goods. Although Small and Medium-sized enterprises (SMEs) are a large part of every market economy they were almost non-existent in these economies (McMillan & Woodruff, 2002). Multi-nationals who enter these diverse markets will find contextual differences that require different adaptations. This research explores the lessons garnered in South African Public Private Partnerships (PPPs) where Multinationals are usually leading members of consortia Joint Ventures (JVs), because of their expertise, specialization and experience. Of particular interest is to find if synergy could be found between divergent interests of SMEs promotion by the host country, and profit maximization by the Multi-National Companies (MNCs).

LITERATURE REVIEW

Pessoa (2006) defines a *Public Private Partnership* (PPP) as a sustained collaborative initiative between the public sector and the private sector to achieve a common objective while both players pursue their individual interests. The third "P" of a PPP assumes a joint alliance beyond a traditional contractual relationship. However, Pessoa (2006) contends that the reality of PPPs in developing countries is based more on "complementarity" and not on cooperation. This happens while PPPs are increasingly becoming popular institutional arrangement, as they are perceived to remedy a lack of dynamism in traditional public service delivery (Jamali, 2004). While it looks like PPPs can be an efficient form of enhancing well-being and of promoting growth, the truth about the impact of PPPs is somehow out there waiting to be discovered (Pessoa, 2006). It is for this reason that all stakeholders involved in PPPs in developing countries share an interest in knowing more about their effects (ibid.). The interest of this study is to see how PPPs affect SMEs in transition economies, taking the experience of South Africa in one of the longest PPP projects.

The Role of SMEs during Transition

The SMEs sector carries great hope and great burdens in the evolution of all transitional economies (McIntyre, 2001). Although the role of SMEs in generating employment and an atmosphere of social stability cannot be gainsaid, hopes that this sector by itself will have systems-dynamizing and transformational effects have not been realized (EBRD, 1995). Successful development and deployment of SMEs allow desirable changes to take place elsewhere in the system without affecting or threatening social peace. This is because SMEs are able to absorb resources and workers from large enterprise sector, creating a labour market when large enterprises are being re-orientated and re-organized, thus avoiding disturbing social peace (McIntyre, 2001).

In China the start-up firms drove China's reform momentum; they were arguably the single main source of China's growth. The other ex-communists economies had similar experiences, this despite the fact that reformers did not anticipate their emergence and influence (McMillan & Woodruff, 2002). The omission of SMEs in the theoretical understanding and practical functioning market economies is predicated on market automaticity assumptions – i.e. spontaneous processes can be counted on to create new, viable entities to fill the interstices between large organizations (Riskin, 2001). Overlooking SMEs is detrimental to a complete

scholastic discourse on transition because globalization compels MNCs to interact with local SMEs, either positively or with sour consequences. According to Buckley and Casson (2003) most international business scholars, would rather influence the boardroom than the office of the president, where broader political, social and economic issues are analysed, simply because business pays better. The over-emphasis on business has led to a situation where advice that could have been given to politicians is withheld resulting in the perpetuation of weak institutions in host governments, a situation that is sometimes unfairly advantageous to MNCS.

Weak institutions in host countries

In many transition economies reformers and advisors share an appreciation of speed and secrecy, since this could musk personal appropriation of public assets where self-dealing is rife, masqueraded as 'expert' recommendation (Wedel, 1998). Real markets function 'successfully' only when a fairly elaborate set of surrounding institutional, infrastructural and behavioural conditions are already in place and are internalised as a cultural norm. Although technocrats who are in favour of allowing time to build market infrastructure, are accused of opposing market reform, this approach avoids a simplistic view of capitalism as a self-organizing system of natural equilibrium (McIntyre, 2001). Where there is no adequate institutional preparation, there will be a long-term dysfunction of the new system in transition, as was the case in Russia (Kolodko, 1999). This is manifested in extortion of bribes by bureaucrats, a lack of market-supporting institutions like courts to enforce contracts and unobtainability of loans from banks (McMillan & Woodruff, 2002).

Besides weak institutions in host countries, they also lack created assets like infrastructure and human capital (Narula & Dunning, 2000). Many transition countries today continue to wrestle with persistently high unemployment rates even though the 'transition' path has been embarked on for over a decade (Aidis, 2005). Aidis (2005) posits that a strong SME sector could provide further employment opportunities and contribute to economic growth as well as the development of the competitive market system. However, private business in transition economies is confronted with a multitude of barriers; the most important are *formal barriers* such as high taxation and general regulatory environment (Hashi, 2001); *informal barriers* like weak regulation implementation, corruption and unfair competition from a large informal economy (Bartlett & Bukvic, 2001). This shows that although SMEs are important to transitional economies the general environment must be conducive for their growth and survival. These critical requirements are discussed next.

Critical Requirements of SMEs

Development Economics research demonstrates that the SME sector by itself will not create a successful economic growth, without supporting local-level institutions, a surrounding context of successful large enterprises and facilitative overall demand conditions (McIntyre & Dallago, 2003). SMEs do not normally thrive without a set of continuing links to larger entities and measures to assure them market access (McIntyre, 2001). SMEs need large enterprises as a source of inputs and market for their outputs, thus a synergistic relationship between the SME and the large enterprise sectors is critical to avoid a zero-sum environment where success of the small is secured at the detriment of the large (ibid.). SMEs during transition are also crucial as a source of innovation potential and job creation possibilities (Aidis, 2005). The

MNCs entering transition economies need SMEs as they have extensive knowledge about government relations, laws and customs, on the other hand SMEs attain managerial and technological expertise from MNCs (Steensma & Marjorie, 2000). In order for the host transition economy to benefit from the MNCs, knowledge transfer mechanisms have to be understood.

Knowledge Transfer Mechanisms for SMEs

The processes of learning from an MNC partner willing to share knowledge are different from learning from unrelated businesses (Meyer, 2004). The knowledge spillovers come on the basis of: demonstration effects and the movement of labour. Within MNCs, even rank and file staff acquires skills, attitudes and ideas on the job through exposure to modern organisation forms and international quality standards. Many entrepreneurs of local firms started their careers working for MNCs, where they learned vital skills (ibid.). When MNCs work with local SMEs, the *technology gap* hypothesis proposed by Gerschenkron (1962) which stipulates that spillovers are increasing with the difference in technology levels between domestic and foreign firms in the industry, could be applied. If a relationship is a joint venture, two partners share their resources in return for access to the partner's resources and this can lead to mutual learning, and thus extend linkages and knowledge transfers in the local business community (Meyer, 2004).

METHODOLOGY

The methodological approach adopted in this research was phenomenological. Since the study is essentially about human behaviour and experience, it could only be effectively interrogated by having direct access through the lived experiences of the Black owned SMEs in PPPs JVs using interviews to assess their experiences. A phenomenological approach was adopted because it is holistic, with a primary focus on human experience and sustained contact with people in their natural experience (Munhall, 2001). The phenomenological paradigm was selected in this research because its qualitative approach is holistic in orientation and it treats the phenomenon as a whole system as it searches for patterns that lie with the boundaries of the research environment. Its empathetic inclination attempts to understand phenomena holistically from the perspective of the participants (Cupchik, 2001).

Yin (1984) cites the main reasons for selecting a research method as firstly the type of question posed; embedded in this research are questions of *how* and *why,* thus militating the use of a case study. *How* in the sense of establishing the approach adopted by Multinationals and the government in implementing SMEs involvement in PPPs and also *why* they were targeted given the history of South Africa. Case studies are also useful when the researcher has minimal control over activities and when the main focus of the inquiry is on a contemporary phenomenon in the real-life every day context (ibid.). Interviews formed a critical part of this research and through them respondents related their lived experiences. It was not expected that their stories were going to be objective 'facts' but they were rather authentic accounts of subjective experiences. That is why as much as possible it was intended "to formulate questions and provide an atmosphere conducive to open and undistorted communication" (Gubrium & Holstein, 1997, p. 116). Open-ended interviews with consortium shareholders and contracts managers of Black owned SMEs sub-contracted to the main Facility Management (FM) company involved in the operations of the project

were conducted. Probes served only to give direction to the discussion but the interviewees freely articulated the *hows* and *whys* of their JV experiences.

DISCUSSION AND ANALYSIS

The case study used for this research is an 850-bed referral hospital in the province of Kwazulu Natal just outside Durban. The Inkosi Albert Luthuli Central Hospital (IALCH) is named after the first president of the African National Congress (ANC) and a first South African Nobel prize winner Albert Luthuli, and it is one of the most modern in the country, boasting the novelty of being the first hospital in Africa to go paperless. All patients' records and scans are captured and retrieved electronically. When it opened it was the first provincial PPP project in the country. Consequently there was a concerted provincial and national governments' effort to instigate practical Black owned SMEs (mostly start-ups) involvement at all levels as the intention was that the project would be an example of best practice. The project has three tiers; the first is the shareholder level where the Previously Disadvantaged Individual(PDI)/black project sponsor, a PDI women's group, Medical supplier, Facility Management (FM) and Information Technology companies are all shareholders in the Special Purpose Vehicle (SPV), christened IMPILO.

The second tier is operational where all the companies except the PDI women's group are sub-contracted to the main SPV company at the first tier. At the third tier twelve (12) sub-sub-contractors are all sub-contracted mostly to the FM company and they perform various FM tasks from security, cleaning, portering, catering, waste management to store and warehouse management. The PDI women's group comprises of two different companies which teamed up for this project and they do most of their tasks together. They formed JVs with a number of reputable established companies to perform six different activities but they are all ultimately answerable to the main FM operator. Highly specialized activities like medical waste management are outsourced to independent vendors who have periodic contracts with the FM operator. The discussion section in these project looks at how Black owned SMEs were involved in this project, the role they played and experience they gained. This discussion is intended to provide a practical example that can be scrutinized for possible adoption elsewhere in Africa and other transitional economies.

South Africa has a very well developed legal framework that guides the PPP implementation. Since PPPs by nature have a protracted procurement mechanism, this helps the government to scrutinize the consortia proposals to ensure that there is congruency with government's empowerment policy. Most importantly it is the requirement for the inclusion of black owned SMEs as sub-contractors whenever possible. Their inclusion is a contractual requirement that must be verified during adjudication, and this is done to screen out fronting. The financial trickle down to the PDIs is strictly monitored throughout the project. All the international players also have to demonstrate a workable skills transfer plan that is monitorable because of the milestone they would have committed themselves to.

Project Approach

The approach that was taken at IALCH was to ensure that all the unskilled labour is first sourced from the surrounding community to ensure that the locals are the first ones to benefit from the scheme. There was a bursary fund availed to local high

school matriculants enabling them to study for professions that are related to skills required at the hospital. The hospital gave them experiential training when this was required and there was no strict requirement to serve the hospital once they have completed their studies. The longevity of the project had other positive spin-offs; pre-school education of the staff's children had to be offered onsite, since there was no good school in the vicinity, as the surrounding Cato Manor area is an impoverished township designated for Indians and blacks under the apartheid system. This school is open to the members of the community, for those who can afford and it is providing a world-class foundational education that would not be easily accessible to the locals.

The PPP requirement of PDI SMEs involvement led to the formation of start-ups who wanted to be involved in this project. Although some of them were professionals, they had never been involved in business as this was the preserve of whites in the past. After working in the project most of them could see their businesses growing, and some had already started other initiatives outside the project. This is what one of the ladies had to say*: "But it is has been worth it. ... there is ownership there. You've learned employing people… paying them… how to deal with a workers' strike…. we've heard it all. I started a company with other professionals and we invested in a big pharmaceutical multinational company, which is a good investment."* The approach of the Facility Management (FM) Company was for them to share office space, and have a direct daily interaction. This has helped a great deal: " *you see us as service providers we are run by a head company FM operator which sub-contracts all the work to us and everything is being monitored every second of the day. So all service providers are keeping up to whatever service standards they need to keep up to."* Besides the *demonstration effect* from sharing space with the main contractor some of the managers were seconded to other sites of the FM Company to be mentored in different scenarios.

It is not only the management that was targeted but the rank and file staff benefitted by working in a world class facility. The FM Company went an extra mile for instance by ensuring that everybody who works in this facility is computer literate, from cleaners upwards. This skill is not only helpful here at the facility but it is going to be of benefit even when people leave the facility to work elsewhere. Since most of the people had not worked in a similar environment because the companies were mostly start-ups, the *technology gap* was big. The emphasis on the MNCs to have the ultimate performance responsibility, ensured proper training and mentoring of the SMEs, which was not only going to help the performance of the project but was a foundation for a whole new entrepreneurial opportunities.

Generalization of Findings

Although the transition economies are diverse all the lessons learned from elsewhere have to be contextualized, it is worth comparing lessons from South Africa with experiences articulated above in literature. Since start-ups were crucial in driving the economies of most countries, PPPs can provide an incubatory environment where these are nurtured under the government's watchful eye and given enough time to mature, since PPPs have a long duration. Without government intervention and assistance the success of SMEs is compromised, and with that the health of the economy. The emphasis by South Africa to include PDI SMEs has resulted in confident new business people that were suppressed previously by the very state

institutions. And this is instructive to other governments not to leave the economy to self-propel as this could result in exclusionary practices detrimental to the SMEs.

Although some transitional economies are not showing much by way of emerging from their transition, the weak institutions could take greater blame for not providing a conducive environment amenable to weak SMEs. The South African government took a lot of time studying the UK PPP model before adapting it to South Africa; this happened in a country that already had an advanced business culture. Whereas speed and secrecy has led to a lot of self-dealing and corruption in other jurisdictions; screening of proposals, for SMEs meaningful involvement in PPPs and protracted negotiations have mitigated fronting and malicious compliance in South Africa. In South Africa the special legislation: *codes of good practice for BEE involvement in PPPs specifically* deals with unique PPP environment in involving PDI SMEs in projects. This put the MNCs in a position where they know what the government goals are in involving SMEs in PPPs and this has mostly improved congruency and contractual relations. The requirement to form JVs with the local SMEs has served to improve the *demonstration effect* of the locals learning. Some members of the sub-contractors were already looking beyond the project where they can deploy the skills they had learned. The 'quantum leap' in skills attainment could not have been garnered within that time if they were not partnered with experienced MNCs. This confirms the importance of MNCs assistance in skilling the local SMEs especially where the *technology gap* is big.

CONLUSION

Although transition economies are diverse and unique, the South African experience can be emulated and adapted elsewhere. PPPs longevity is amenable to start-ups nurture, and start-up development is critical as they are drivers to any transition economy growth. *Demonstration effect* is very effective when entering *Greenfield* markets (undeveloped/un-entered) where experience is wanting, as the South African black community was. This militates towards the case of JVs which are a prerequisite in PPPs. Where there is a huge *technology gap*, comparatively JVs could be the most effective tool. This is instructive as the technology gap should not be a hindrance in involving local players.

State intervention is critical to SME success to mitigate exclusionary practices by MNCs, and PPPs provide a long-term incubatory environment for SMEs. Well articulated laws are very helpful during transition when PPPs are adopted, as project failure could lead to a lot of negative economic ramifications. Openness and transparency is critical for PPPs in luring MNCs who yield so much knowledge to SMEs in PPPs. The uniqueness of South Africa militates against the generalizability of this study but the lessons are instructive to most transitional economies.

PUBLIC-PRIVATE PARTNERSHIPS: A LEGAL VEHICLE FOR ROAD CORRIDOR DEVELOPMENTS

Prof. Andries C. Hauptfleisch[1], Prof. Johannes J.P. Verster [2] and Dr. Maléne M. Campbell [3]

[1,2] *Department of Quantity Surveying and Construction Management, University of the Free State, PO Box 339, Bloemfontein, 9300, South Africa*

[3] *Department of Urban and Regional Planning, University of the Free State, PO Box 339, Bloemfontein, 9300, South Africa*

ABSTRACT

The development impacts of road corridors are important and substantially greater than the cost of the actual road construction. Resultant property and socio-economic development is widely discernible, but difficult to quantify. A suitable legal and economic vehicle is required for execution of projects making public-private partnerships (PPPs) attractive. The theoretical bases for these developments have been analysed and evaluated. The Maputo Development Corridor (MDC) stretching over 590 km from the economic heartland of South Africa to Maputo, the capital of Mozambique, was used as a case study. Extensive literature reviews covering the period since inception in 1996 to date were undertaken. Quantified studies were conducted and qualitative observations made. The study results indicate consensus that many development objectives are met, whilst others are difficult to quantify. Reliable statistical data on traffic movements, harbour usage, etc. are available, but the substantial "trickle-down" effect observed is difficult to quantify. PPPs are hailed as desired vehicles, if not a mandatory requirement to create sustainable infrastructure, such as road corridors.

Keywords: nodal points, property and socio-economic development, spatial development.

INTRODUCTION

The development impacts of road corridors are important and substantially greater than the cost of the actual road construction. Resultant property and socio-economic development is widely discernible, but difficult to quantify. A suitable legal and economic vehicle is required for execution of projects, making public-private partnerships (PPPs) attractive. PPPs are also known as P3s and in the United Kingdom mostly called PFIs (Private Finance Initiatives). The theoretical bases for these developments have been analysed and evaluated. The Maputo Development Corridor (MDC) stretching over 590 km from the economic heartland of South

[2] versterj@ufs.ac.za
[3] CampbeMM@ufs.ac.za

Africa to Maputo, the capital of Mozambique, was used as a case study. This road corridor is known and mapped as the N4 (National Highway 4), a toll road. Trans African Concessions (Pty) Ltd (TRAC) is the concessionaire that built and operates the MDC. Extensive literature reviews covering the period since inception in 1996 to date were undertaken. Quantified studies were conducted and qualitative observations made. The study results indicate consensus that many development objectives are met, whilst others are difficult to quantify. Reliable statistical data regarding traffic movements, harbour usage, etc. are available, but the substantial "trickle-down" effect observed is difficult to quantify. PPPs are hailed as desired vehicles, if not a mandatory requirement to create sustainable infrastructure, such as road corridors.

PROBLEM STATEMENT, OBJECTIVES AND DELIMITATIONS

The **problem** investigated is the following:
Do PPPs as legal vehicles have the ability to provide additional and suitable procurement avenues for fixed asset developments?

The **objectives** of the study cover the following:

- To conduct a survey of the typical structure of PPPs as legal vehicles for developments
- To describe the theoretical and planning and policy aspects underlying the development of corridors
- To utilise the MDC as a case study, reflecting the outcomes of an extensive PPP road corridor development. Empirical research was undertaken to establish perspectives of beneficiaries and other stakeholders

The following **delimitations** apply to the study:

- PPP fundamentals portraying perceived practice are provided, while a comprehensive practice guide is not provided.
- The MDC is used as case study to demonstrate outcomes, expanded where relevant, to reflect broader regional and African perspectives.

RESEARCH METHODOLOGY

The following research methodologies were applied:

Qualitative research methodologies

An internet survey was undertaken to establish the salient features of typical formats of PPPs. This has been reduced to descriptive research outcomes, thus a summary reflecting general practice.

Varying theoretical perspectives on regional planning as well as development corridors were compared and concepts related to corridors and their theoretical foundation revisited. Some sectors and components of socio-economic development have been included as well as main activities that have occurred since the inception of the MDC.

The changing South African government approaches to regional planning were also studied and qualitative, unstructured interviews conducted.

Quantitative research methodologies

Purposive sampling was applied and quantitative structured questionnaires were administered to business owners, -managers, government officials and professional people in the main centres, either on or very close to the corridor, during June 2011. In South Africa 76 questionnaires were completed and in Mozambique 14.

PUBLIC-PRIVATE PARTNERSHIPS AS LEGAL VEHICLES

PPP Constraints

PPPs are internationally used to create infrastructure. A number of countries have been identified by commentators over a several years as the "leaders" in the field. This report reflects some of these countries as well as some other first world countries that potentially have the skills and capacity to utilise PPPs. Many constraints hamper the development, application and benefits of PPPs to varying degrees, all over the world. The following are the most common constraints that contribute to the complexities inherent to PPPs, also contributing to the generally slow development of PPPs:

- Some concerns regarding privatisation have been transplanted to PPPs though the latter are not synonymous to privatisation, but an alternative procurement model that can be exploited in many ways.
- The most desired terrain for PPPs is in high-value projects, typically in $ billions, the magnitude of which overstimulates causative positions.
- PPPs are very long-term projects that do not only involve the provision of projects, but also "living" with them, often for generations. It is problematic for decision-makers, particularly civil servants, to commit the public for generations. The private sector in turn has to evaluate the road ahead, particularly financially, for unheard-of contractual terms and risks.
- Although not based on much quantified research, there is ample speculation that "private partners" are receiving unacceptably high returns from PPPs.
- The ability of governments to ensure PPPs' accountability is problematic in light of the complexities.
- PPPs are contractual arrangements, practiced legal vehicles to achieve the objective of meshing public sector physical facility needs, with the overall capacity, often including financial capacity, of the private sector. It should thus be possible to structure PPP agreements that ensure mutually beneficial outcomes.
- The above constraints seem to retard development, to the detriment of both the public and the private sectors. The lack of universal (or national) PPP procurement guidelines and model contracts/legal documentation increases risks and strains implementation.

International perspectives

The following perspectives regarding a number of countries shed light on the utilisation of PPPs:

Australia

Australia is presently hailed by many as the leading nation regarding PPPs. The following literature reflects the Australian position:

- The Australian Government (2008) overview: National Public Private Partnership Guidelines, reflects the following:

- Infrastructure is the main focus of PPPs with the private sector providing design, construction, financing, maintenance and delivery.
- Government contributes land, capital works, risk sharing, revenue diversion, purchasing of agreed services.
- The private sector receives payment from government or users of economic infrastructure (including toll roads: "user-pay") contingent on the private sector's performance.
- PPPs are not synonymous to privatisation.
- Table 1 shows the key difference in procurement methodology in Australia, portraying to a large extent the universal position.

Table 1: Comparison of traditional procurement and PPPs

Traditional procurement	PPPs
Government purchases an infrastructure asset	Government purchases infrastructure services
Short-term design and construction contracts (two to four years)	One long-term contract integrating design, build, finance and maintain
Input-based specifications	Output-based specifications
Government retains whole-of-life asset risk	Private sector retains whole-of-life asset risk
Payment profile has a spike at the start to pay for capital costs, with low ongoing costs	Payments begin once the asset is commissioned. The payment profile is relatively even, reflecting the level of service provision over the longer term of the contract
Government is usually liable for construction time and cost overruns	Private contractor is responsible for construction time and cost overruns
Government operates the facility	Government may or may not operate the facility
Government manages multiple contracts over the life of the facility	Government manages one contract over the life of the facility
Often no ongoing performance standards	Performance standards are in place. Payments may be abated if services are not delivered to contractual requirement
Handover quality less defined	End-of-term handover quality defined

- The key steps in investment and procurement decision-making are portrayed in Figure 1, also reflecting universal methodology.

Figure 1: Key steps in investment and procurement approval

- The Australian Government (2008) *National Public Private Partnerships Policy Framework* sets the following objectives:
  - Encourage private sector investment in public infrastructure.
  - Encourage innovation.
  - Ensure rigorous governance of the selection of PPP projects.
  - Provide a framework for streamlined procedures.
  - Clearly articulate accountability for outcomes.

- Infrastructure Partnerships Australia ([s.a.], online) reports the following key findings on PPPs and traditional procurement:

- PPPs are clearly superior in cost-effectiveness.
- PPPs are expected to contribute a 10-15% share of infrastructure during the next decade. This will generate $6 billion (Australian) in potential community benefits.
- PPPs are generally executed faster than traditional projects, being superior in terms of cost and time, improving with size and complexity.
- Contrary to popular belief, PPPs are more transparent than traditional projects.
- PPPs provide an additional procurement avenue that furthermore provides benefits far beyond the construction time of the projects.

Canada

PPP Canada was created as a Crown Corporation with an independent board of directors. Its mandate is to improve the delivery of public infrastructure by achieving better value, timelines and accountability to taxpayers through PPPs.

PPPs are utilised by federal government, also increasingly being viewed more favourably by provincial governments in Canada.

PPP Canada (2010-2011) reflects the following in their Annual Report on PPPs:

- PPPs are delivering a broad range of public infrastructure on-time, on-budget projects, reducing risk and maximising value over the entire project life cycle. This includes transportation.
- Integrated solutions regarding design, construction, finance and operation of public infrastructure are developed. PPPs draw leading expertise together in all aspects, using the discipline of competition and capital markets to ensure private sector delivery.
- Federal government is increasingly dedicated to promote the use of PPPs.
- Federal government has committed to the future assessment of the suitability of federal projects for PPP application. All projects with a capital cost in excess of $100 million (Canadian) will be required to be assessed for PPP suitability.

United States of America (USA)

PPPs in the USA are regarded as an evolving market with new opportunities according to Chase (2009), who regards PPPs as moving through three generations. PPPs have moved on from first generation monetisation deals, now in transition from the second generation ad hoc projects to the present third generation, where projects with potential should be selected and advanced to well-structured PPP programmes.

Private investors and public pension funds are very specific that they require infrastructure in their portfolios.

During the first generation, public officials for the first time considered innovative private financing. Some unsatisfactory results, however, discredited PPPs. The second generation also posed problems blamed on public sector fragmentation. However, success has been achieved with corridors and user-pay projects. Improved alignment of interests, incentives and risk sharing between public and private partners have produced better results. But, the lack of a comprehensive PPP programme still results in ad hoc projects in project partnerships, each time reinventing the wheel.

 ISBN: 978-1-84219-840-7 .

Performance-based approaches have evolved in the third generation, now fostering the development of policy and detailed implementation processes through PPP units in government agencies.

Reinhardt (2011) recently reported the following status:

- Noteworthy PPP progress has been made in the water market with quality improvements due to PPPs.
- Buildings provide an opportunity to be exploited by gains that could be made on the misallocation of risks costs as high as 30% of project costs which may be saved by appropriate risk distribution.
- Highways have been developed on an on-off PPP basis but are not developing consistently. Yet, Canada, starting at the same time, has established numerous very successful PPPs, presently at the rate of $300 million (Canadian) annually.
- As yet there is not a financial formula for USA highways. There seems to be general consensus that the creation of an intelligent coast-to-coast highway system is only possible on a user-pay basis, thus tolls.
- Like Puerto Rico, it is time that government (USA) realise they are broke and cannot meet expectations. Like Puerto Rico, the USA government could discount this fact and utilise PPPs to tap into private sector capital, creativity and long-term diligence. Puerto Rico is very successful in this regard.

United Kingdom

The UK more often refers to a Private Finance Initiative (PFI) than to a PPP.

The PPP Forum (2011) describes a PFI as a procurement method where the private sector finances, builds and operates infrastructure and provides long-term facilities management through long-term concession agreements. The lifespan of these concessions is at least 25 years. Payment is only made if services are delivered according to the requirements of the concession.

The National Audit Office in 2003 estimated that 73% of procurement under traditional methods was delivered over budget and 70% was late.

PFI from both a public and a private perspective was challenged to address the above deficiencies.

PFI projects have now probably become the largest infrastructure sector in the UK. Over the past fifteen years the PPP Forum has reported over £60 billion worth of projects signed. This includes almost 100 hospital schemes, more than 100 education projects, more than 800 school projects, 43 transport projects and over 300 other operational projects.

Risk is distributed in PFI projects and the private sector accepts the risks that they can best manage. Construction and design rest with contractors; finance providers take the financial risk; etc. Typical PFI participants are construction contractors, insurance companies, banks, equity investors, professional advisors and obviously the public sector participants from transport, health, education, etc.

 ISBN: 978-1-84219-840-7 .

It is estimated that PFI projects are about 2,25% more expensive than traditional projects, attributed to the cost of private sector finance, versus lower-cost public finances.

Europe
The European view of PPPs is overly positive, but politically challenged.

The major motives for moving towards PPPs in Europe are macroeconomic, budgetary and improving efficiency of public service delivery, as reported by McQuaid and Scherrer (2008).

In some European countries there is a strong preference for consensus societies. The political context in Europe is also different from that in Anglo-Saxon countries. There is a reluctance to increase the level of direct privatisation. This position is also confirmed by recent political developments in a strained Eurozone environment.

However, some regard PPPs as the middle ground, and not as privatisation. The uptake of PPPs in Europe is slow, but with the impact of high tax burdens and restrictions placed on governments to borrow money, PPPs are becoming attractive to raise private funds to close infrastructure gaps.

Overall there appears to be considerable scope to develop PPPs in Europe.

South Africa
- PPP Manual
  The Department of Finance (2004) has created a PPP Manual. In the preface the following statement is made by the minister of finance:

  > *National Treasury's PPP Manual* is indeed a world first. It systematically guides public and private parties through the phases of the regulated PPP project cycle for national and provincial government, unpacking policy and providing procedural clarity as it does so. It draws on South African project experience to date and on best international practice, without infringing on the authority of accounting officers and authorities. It sets rigorous risk-assessment standards by which government will make affordable project choices that best leverage private investment for quality public services.

  This manual contains sections on regulations; code of good practice; inspection; feasibility study; procurement; management of agreements; auditing; accounting; project finance.

  Although the PPP Manual is available, and some very successful projects, such as the MDC, had been undertaken even before the manual existed, the PPP procurement strategy has lost steam. There appears to be substantial private sector appetite to engage in PPPs, but the success rate of bringing PPPs to fruition is low. Private sector construction contractors have recently indicated that it is becoming too uncertain, cumbersome and costly to pursue proposals despite successful projects having been executed.

- The MDC

The MDC is a success story, also confirmed by the continued smooth operation of the legal format. The following are some of the noteworthy observations:

- The South African government's role included entering into agreements with the government of Mozambique and TRAC, which included facilitating the upgrading of an existing road to a well-managed and well-maintained road corridor of significant importance.
- The Build-Operate-Transfer (BOT) agreement provides for the N4 toll road to become the sole property of government after 30 years. Renewal is an option.
- The development equity was secured by a 20% contribution from the construction contractor consortium (including some international contractors) and 80% debt by four major banks.
- The road is so successful on a user-pay basis that it was refinanced in 2006 under improved terms and release of capital.
- Shareholders have been able to successfully trade their interests in TRAC. TRAC is thus a marketable investment instrument.

EXPERIENTIAL KNOWLEDGE GAINS: INTERNATIONAL LITERATURE REVIEW

The following experiential PPP knowledge gains are universal in character:

- PPPs do not imply privatisation.
- PPPs open additional procurement avenues.
- Key differences between PPPs and traditional procurement as indicated in Table 1 for Australia, are universal in character.
- Although they present "new" challenges, PPPs as legal vehicles have successful track records.
- There is a sufficient international knowledge base for the successful implementation of PPPs as legal vehicles for procurement.
- The pronounced use of private funds and expertise to create public infrastructure is hailed as an important accelerator of development.
- PPPs are particularly suitable for large and long-term (life cycle) projects.
- Introduction and utilisation of PPPs require concerted effort and dedication from all stakeholders.

THE MAPUTO DEVELOPMENT CORRIDOR: A CASE STUDY

Theoretical aspects regarding regional and spatial planning

According to Gertler (1972), regional planning is directed towards facilitating development, private or public, in a manner that results in areas where people settle, establish regional communities and create the best environment and the soundest use of resources that civilisation is capable of effecting. Regional planning is viewed as a phenomenon which distributes economic resources centrally between regions in an effort to achieve certain regional and national objectives. Furthermore, regional planning is a necessary endeavour to address pressing economical, physical, social and environmental problems of regional significance (Glasson, 1978). Friedmann and Alonso (1964) define regional planning as a process which integrates development at a national level, and increases investment opportunities through strategic decision-making and planning endeavours at a regional level and economic development programmes at subnational level.

Glasson (1978) is of the opinion that growth occurs along diverse channels and is intensified at certain development poles with variable intensities. Perroux (cited in Glasson, 1978) propelled this theory and argues that intensified development should occur in certain growth points or economic spaces from which outward-working forces are generated and to which inward-working forces are attracted. Jooste (1994) postulates that the growth pole theory is one of the most renowned strategies to ignite development in underdeveloped regions, especially rural ones in a regionalised or nationalised planning system. He further argues that the main objective of regional planning theory is to encourage economic dispersal and to counteract the process of isolation and disintegration of marginalised areas. The rationale behind this theory is premised in the principle of agglomerations and transmissions of economic benefits through certain spheres of influences or poles. The theory highlights the importance of intensified economic development at certain locales with divergent benefits across certain spheres. Gauteng and Maputo can be seen as agglomerations of economic and industrial activities while the MDC may be seen as a channel (axis) to spread the economic and social benefits from and to these two growth poles.

Figure 2 diagrammatically reflects the present MDC, also indicating "development areas" into Swaziland, capital city Mbabane (o) to the east, and the northern regions of the Limpopo province with dual development nodal points at Polokwane (l) and Phalaborwa (k). Other corridors also project out of the terminal nodal points of the MDC at Pretoria (a) to (m)/Johannesburg (b) to (n) (Gauteng, South Africa) and Maputo (j) (Mozambique).

Figure 2: Diagrammatic presentation of MDC with development arms

The Japan International Cooperation Agency (JICA) (2010:1-276) has prepared a comprehensive study titled *Preparatory Survey for Southern Africa Integrated Regional Transport Programme*. This study was conducted to cover the region reportedly with the highest cross-border traffic in Africa, covering the eight most

 ISBN: 978-1-84219-840-7 .

southern countries. Figure 3 indicates the existing 18 corridors, for which in each case comprehensive trade movement data is available. Some of the corridor positions are (probably) not geographically 100% correct, but the overall presentation is acceptable for the purpose of this paper. From a socio-economic perspective, comprehensive data is available for each of the countries regarding demographics, scale of economic activity, governance and the business environment. From this, a corridor development priority programme has been created for southern Africa.

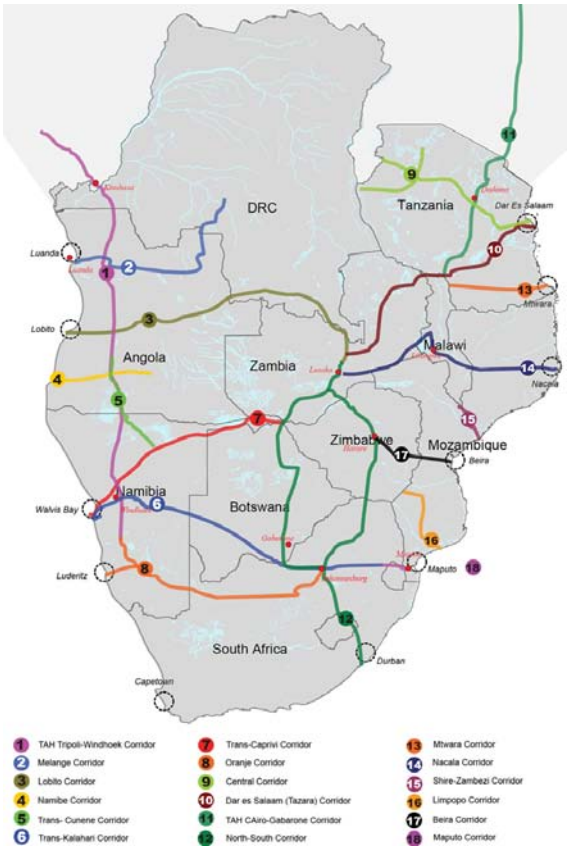

Figure 3: Southern Africa Transport Corridors and Major Ports (JICA, 2010: 2-22)

Government initiatives: PPP as vehicle

The objective of the National Physical Development Plan (South Africa, 1975) was to link existing metropolitan areas with identified or future growth poles by means of development corridors. Geyer (1986) found that some corridors were not supported by secondary development centres (nodal points) on one of the terminal ends of the axis, or were stretching over too long distances to be influential in making development realistically viable. The greater the distances between centres, the stronger these centres should be as development centres. In some cases so-called corridors are not corridors but only finger developments with no equilibrant development centre at the other end.

The Spatial Development Initiatives (SDIs) of the South African Government, conceived in 1995 by the Cabinet was an attempt to improve investment in those areas where the greatest potential for growth exists (Jourdan, 1998). The MDC satisfies economic realities, Maputo being the closest harbour to Gauteng. In the 1970s 40% of the export from Gauteng went through this port, but this faded away due to socio-

political factors (Jourdan, 1998). However, strong growth has subsequently been experienced, following new political dispensations, also manifested by the MDC.

The South African government's more recent National Spatial Development Perspectives (NSDP) of March 2006 provides a framework within which to discuss the future development of the national space economy. The NSPD reflects localities of severe deprivation and need; of resource potential; of infrastructure endowment; and of current and potential economic activity by describing the key social, economic and natural resource trends and issues shaping the national geography.

The MDC is regarded as a most successful PPP, with the concessionary already investigating further similar developments in Africa. In contrast to the success of the MDC (and several other similar corridors in South Africa) as a PPP project, the government agency, South African National Roads Agency Ltd (SANRAL) has recently completed a Gauteng toll-road system (that links the MDC with Johannesburg and Eastern Gauteng) with disastrous financial consequences. Allegations regarding exorbitant tolls and corruption have led to a supreme court ruling suspending tolls in April 2012, the outcome of a public outcry, legal action and possible payment boycotts. In stark contrast, numerous PPP projects are running smoothly, being managed by private sector concessionaries.

A "mid-term" overview

Söderbaum and Taylor (2003:6) compiled, with the aid of seven co-writers, a book, *Regionalism and Uneven Development in Southern Africa*, providing an in-depth analysis of the topic, focusing primarily on the MDC. The perspective they hold provides an important balance sheet, reflecting, albeit negatively, on the impact of the MDC. The following abstract, in some instances reworded and/or summarised for this report, is relevant:

The MDC is based on four key objectives:

1. To rehabilitate the primary infrastructure network along the corridor, notably road, rail, port and dredging, and border posts, with the participation of the private sector in order to have minimum impact on the fiscus.
2. To maximise investment in both the inherent potential of the corridor area and in the added opportunities which infrastructure rehabilitation will create, including the provision of access to global capital and facilitation of regional economic integration
3. To maximise social development, employment opportunities and increase the participation of historically disadvantaged communities
4. To ensure sustainability by developing policy, strategies and frameworks that ensure a holistic, participatory and environmentally sustainable approach to development

Concluding remarks by Söderbaum and Taylor (2003) suggest, contrary to popular belief, that the MDC is a failure as the stated objectives 3 and 4 have not been achieved. They fail to acknowledge or fundamentally evaluate the real effect of the "trickle-down" impact or to provide guidance as to how objectives 3 and 4 should be practically brought to fruition. Guidance is also not provided as to how the desired social development and employment resulting from the MDC are measured, or are measurable. The positive outcomes regarding key objectives 1 and 2 are evaluated by

Söderbaum and Taylor (2003) as negative, probably because 3 and 4 are emphasised as failures. These views are fundamentally flawed and contradictory in view of the obvious positive outcomes of the MDC project.

African continent
Jourdan (2008:20) reports:

> An African Development Corridor desk-top study was undertaken by the RSDIP(Regional SDI Programme of the SA Department of Trade & Industry) & Mintek (for NEPAD) in 2006 to investigate the potential and status of continent-wide development corridors, examined in a preliminary fashion the potential of DCs across Africa. It makes the case that Africa's physical and social infrastructure needs are so large that they cannot be met in any reasonable time frame without substantive contributions from the private sector.

The Japan International Cooperation Agency (JICA) (2010:1-276) study confirms substantial growth in Direct Foreign Investment (DFI) in the region since 2005. However, to ensure sustained development, corridors are a key requirement for growth. JICA (2010:ES-4) states:

> The existing 18 corridors in the region connect local mineral and agricultural resources with global markets. The study proposed re-defining the role of regional economic and transport corridors according to growth scenarios (strategies), building on the growth belt concept, which encompasses the integration of resources, value creation, and global markets.

A World Bank (Africa Region) Summary Report (2010:4-21) regarding Mozambique, states that the further extension of the MDC is anchored in a "growth poles strategy" that supports the position in this report, i.e. that development centres/nodal points/growth poles are key drivers of corridor development. Evidence indicates that "a road is a road" that connects poles, and development tends to take place mostly in the centres/nodes/poles, with the axis benefitting socio-economic development, along the corridor in a catalytic fashion.

Noteworthy in this summary is the lack of specific "social upliftment" strategies, silently supporting the view that private economic development is the driver of development in general. "Social engineering" is not mooted and it could therefore be assumed that "social development" is regarded as an automatic "trickle-down" beneficiary of private sector-led economic growth initiatives.

Observations 2010
An interview with Chief Executive Officer, Brenda Horne (2010) of the Maputo Corridor Logistics Initiative (MCLI) was conducted to obtain a perspective on the ensuing years since 2003, thus observing the resultant outcomes up to 2010. The MCLI, a non-profit company, was registered to create a body where all stakeholders may contribute to develop the MDC in their collective best interest. The MCLI subscribes to the following mission: "To support the development of the Maputo Corridor into a sustainable, highly efficient transportation route, creating an increasingly favourable climate for investment and new opportunities for communities along the length and breadth of the Corridor".

In pursuance of the above, the following provides an overview of the MDC as perceived by the MCLI presently, as was published as an MCLI Editorial in *Export News*, February 2009:

- To date, the private sector has committed an estimated figure of well beyond US$5 billion worth of investments in southern Mozambique and Mpumalanga.
- Some US$70 million has been invested in the priority works programme at the Port of Maputo since April 2003, including dredging and marine operations, cargo handling, terminal and warehousing functions as well as port planning and development. Before the end of 2004, the port had been working 24/7 in full compliance with the highest international security standards, the first African port that is International Ship and Port Facility Security compliant.
- Trans Africa Concessions (TRAC), a founding member of MCLI, has spent US$400 million on the rehabilitation and upgrading of the road from Gauteng to Maputo, with at least another US$400 million to be spent on the road over the balance of the 30-year concession. The fact that this road has drastically reduced travelling time between the two countries has contributed significantly to the increase of traffic and consequently trade. TRAC has indicated that traffic volumes have increased by between 5% and 7% per annum, with truck traffic increasing by 10% per annum.
- By 2007, passenger transport between South Africa and Mozambique had increased by 80% since the lifting of visa requirements between the two countries in April 2005. This phenomenal increase has put pressure on the existing infrastructure at the Lebombo/Ressano Garcia border post, which is being addressed in the planning and implementation of a joint 24-hour one-stop border post scheduled for completion during 2010.

Questionnaire results: Stakeholders 2011

Out of the 76 respondents in South Africa that completed questionnaires and 14 in Mozambique (the relatively low number of respondents in Mozambique could be attributed to most of the people approached not being fluent enough in English to complete the questionnaires and only 89 km of the corridor being in Mozambique) the minority of the South African respondents, 10,5%, had over 20 years' experience in their current field of work while the majority, 40,8%, had fewer than five years' experience. In contrast, the majority of the respondents in Mozambique, 42,9%, had over 20 years' experience in their current field of work while only 7,1% had fewer than five years' experience.

If the substantial "Neutral" and "Missing" responses from Table 2 are ignored (taken as 0), the "disagree" and "agree" categories provide an enhanced and more powerful response, reflected in the columns marked with an *. The figures provided are expressed as percentages based on the data which reflect an opinion.

Table 2 below shows some of the perceptions of the stakeholder respondents regarding the impact of the MDC on general economic growth. The data obtained has been drastically simplified for this report.

Table 2: Simplified MDC stakeholder perspectives

Q1: General economic growth is attributable to the MDC (Result: Agree)
Q2: Business improved due to incentives by government (Result: Disagree)
Q3: Business improved due to revitalisation of Maputo harbour (Result: Disagree)
Q4: The MDC contributes towards wealth creation (Result: Agree)
Q5: The MDC contributes towards job creation in the region (Result: Agree)
Q6: The MDC caused infrastructure development (water, electricity, roads, etc.) in the manufacturing sector (Result: Agree)

Question No.	South Africa					Mozambique

Q6	30	41	29	51	49	21	43	36	37	63

CONCLUSIONS

The presented data on the MDC, particularly the N4 toll road, overall reflects a highly successful outcome. As a PPP it passed the success test in most respects. The main critique is related to socio-economic issues. However, there is neither acceptable evidence that this criticism is justified, nor is it quantified. Benefits stemming from the MDC as a PPP project are overwhelmingly discernible as “trickle-down” results, but difficult to isolate and quantify.

From the qualitative data it could be concluded that the success of corridors as transport routes and, importantly, creators of general socio-economic development, is undisputed. It could be stated that without the successful development, maintenance, border-crossing improvement and optimal functioning of ports, socio-economic development and regional trade growth and integration will be seriously compromised for the entire region. A noteworthy shortcoming in general is the lack of quantification of benefits per capita to support qualitative observations. Quantitative data collection per questionnaire, in the mode of a survey for this study, also presents collective perspectives.

It is also difficult to specifically adjudicate positive developments that emanate from the MDC into detailed socio-economic segments. Local municipalities, especially those on the N4 road along the MDC corridor, see the MDC as an important component in planning and marketing. The positive effects of the corridor are clearly there, and in some instances measurable, but very difficult to quantify according to specific growth in specific sectors. It is rather in the style of a mass movement than individual events. Collectively the data supporting growth resulting from the MDC is undisputed physical development that observable, particularly pronounced around development nodes on the axes, and at terminal development nodes. The terminal development nodes in particular, and some secondary development nodes, show strong support for the development of further corridors. It is clear that regional socio-

economic development, particularly in Africa, will benefit extensively from corridor developments. It is also concluded that the "trickle-down" effect of development corridors calls for further research, with particular focus on quantification of its effect on the different economic sectors.

The overall evidence portrays PPPs as attractive vehicles for the development of road corridors. It adds expertise and financial resources to the creation of road corridors. Regarding Africa, and many other places in the world, PPPs offer a structured legal solution for the enhancement of road (and many other kinds of infrastructure) development. Local and regional needs can benefit from "internationalised" PPP solutions.

Well-structured and -managed PPPs provide satisfactory financial outcomes, expressed as return on investment. Public and private partners should strike a balance between development imperatives and return on investment, in a transparent fashion. Government agencies, like SANRAL, not being primarily driven by "business" motives like a private partner, are seldom adequately equipped with the necessary combination of business and technical skills to bring difficult solutions to the fore at an acceptable risk level.

No evidence was found which indicated that any of the countries described have adequate financial and other resources to responsibly further circumvent the necessity and potential of PPPs for infrastructure development, particularly roads/corridors that offer simple user-pay options.

The following aspects require specific attention to engage PPPs successfully as legal vehicles for the creation of infrastructure:

- Policy and procedure guidelines are to be in place, providing optimal strategies regarding design, build, maintain, manage, finance, skills development, duration and close-out.
- The long-term risk elements could be demised by introducing reviews at certain time milestones, say 25 years.
- Transparency, accountability and reporting, similar to what is expected of public, listed companies, will counter suspicion of profiteering, corruption and other subjectively perceived risks.
- The identified "tradability" of equity and finance indicates the distinct possibility that PPP finance has the potential to become a typical private sector investment instrument.
- PPPs are not a panacea for all problems, but should be regarded as a very viable alternative for many projects that would normally under traditional procurement processes be executed less successfully or perhaps not at all.
- PPPs are complicated, but there is a wealth of successful PPP projects in the world from which lessons could be learned. It is not necessary to reinvent the wheel.
- Various legal frameworks have been tried and tested for PPPs. It is proven common cause to set achievable, satisfactory legal arrangements and risk mitigation.
- The most important missing link is the will and dedication to remove impediments and create policies, structures, procedures and model contract documentation for repetitive application.

CAUSES OF VARIATIONS IN THE COST PER UNIT AREA IN UGANDA

Jessica Nabuuma[1]

[1]*School of the Built Environment, University of Salford, Salford, M5 4WT, United Kingdom*

ABSTRACT:

The use of different depreciation methods, rates and the lack of centralized data source of costs estimates available to the valuers is the chief cause of differing costs per unit area in Uganda which leaves much uncovered ground for research. The findings reveal that variations in the costs per unit area were due to various factors such as; the differences in cost of information sources where several valuers used a single source of information while others used a combination of sources, which also varied from one valuer to another. Another cause of variation was the difference in the percentages that were attached to depreciation and which percentages were also an individual opinion while to others the percentage was established according to the age of the property. The assumptions were also different and some of the assumptions were also extremely exaggerated. Therefore valuers should agree on a standard method of assessing depreciation. Valuers should also agree on the most appropriate source of cost information or get a central source of construction cost information that is available to all valuers in order to reduce on the variations in the final estimated market value when using the Replacement cost method of valuation.

Keywords: Construction Cost, Replacement Cost Method, Valuation, Variations, Depreciation

INTRODUCTION

When carrying out a valuation of a property to ascertain its market value[2], it is ideal to use the Market Approach where direct sales comparisons are used to get the market values of the property being valued. However, in Uganda (Kampala) there is insufficient or at times total absence of data on recent sales and thus lack of comparable, hence most valuers' resort to using the Replacement Cost Method of Valuation. Replacement Cost Method of Valuation also usually referred to as the Cost method/Summation method refers to a method of ascertaining the market value

[1] j.nabuuma@edu.salford.ac.uk

of a property by reference to two key elements; the cost of construction and depreciation (Dr. Geho, 2002). The method is mostly based on the principles of Reproduction cost and Replacement cost. The Cost Method is a method based on the principle of substitution. The principle states that no rational person will pay more for an existing house than the amount for which he could obtain, by purchase of site and construction, without undue delay, a house of equal desirability and utility (Dr. Geho, 2002). The methods of estimating building cost when using the cost method include; the quantity surveying approach, unit-in-place cost, unit comparisons and the cost indexing method. Though valuers may have a standard method of estimating the building cost when using DRC, they usually end up with differing costs per unit area for similar buildings, which leads to very wide variations in the final market value that estimate for the same property.

LITERATURE REVIEW

Kampala has a young property market and thus attracts investors but information about recent sales of properties is unavailable due to a number of reasons. Due to this unavailable information and insufficient data about recent sales of properties, the Replacement Cost Method of Valuation is resorted to by most valuation firms in Kampala when carrying out the valuation mostly of residential properties. Though the method is widely used, valuers tend to return quite varying value estimates on the same piece of property. Variances in values are expected but the ranges evidenced are far too wide and varying. This may be due to fact that there is no exact science on the accepted variance or any literature written on the accepted ranges. Land comparisons are also not readily available when establishing the value of land on which the property is situated. International valuation standards state that; where there is sufficient market data to support the valuation, **Market Value** is derived. In other circumstances, where there is insufficient market data, the result will be **Non-Market Value** (IVSC, 2005). The replacement cost method is used in circumstances where there is insufficient market data, when use of the sales comparison or income capitalization method is not possible, and so the output will be a non-market value. However, when valuing specialized property where possible, the valuer develops land value, cost, and accumulated depreciation estimates from market information (IVSC, 2005: General Valuation Concepts and Principles, paragraph 8.2). In the cost approach, comparable data refer to the cost of building or development, and adjustments are made to account for differences in quantities, qualities, and utility. In addition, analysis of comparable land data and comparable depreciation estimates is undertaken (IVSC, 2005, International Valuation Guidance Note 1, paragraph 5.20.3). The cost method is mainly used on residential properties in Uganda and especially in Kampala city. This is because there is usually insufficient market data on such properties and thus lack of comparisons and hence the valuers cannot use the sales comparison method of valuation neither can they use the income capitalization method.

Conditions That May Lead To Variations In Costs Method Of Valuation

The method implies that there is equivalence between depreciated replacement cost and the market value under conditions of perfect competition, however, in real life there is no perfect competition and imperfections of the property market can result in market value being above or below depreciated replacement cost. Also the amount required to construct a building or a specific property price in the market does not represent the property's market value because some factors such as; special time

transaction considerations, such as a special relationship between the buyer and the seller, besides the transaction may have been part of a larger set of transactions in which the parties had engaged. Another possibility is that a special buyer may have been willing to pay a premium over and above the market value; the price paid does not present the true market value of the property. Also in estimating the cost of new buildings, discrepancies can result due to differences in construction quality that may be assumed by different valuers. Also at times the historical cost method is used but it is usually difficult to determine all historical development costs, in some circumstances, assets and liabilities may be shown at their historical cost, as if there had been no change in value since the date of acquisition. The balance sheet value of the item may therefore differ from the "true" value. Historical cost does not generally reflect current market value. When using the DRC, costs are usually derived from recent construction costs of similar buildings. But there may be marked variations in construction costs by buildings contractors for the same building this leads to variations in the costs per unit area. On the other hand, building costs may be derived from the construction market rather than the real estate market (Whipple, 1995). Different market forces therefore influence them even before depreciation is estimated. Depreciation assessments are largely influenced by personal feelings and there is no common agreement on the methods of refining the depreciation allowance. This usually leads to variations in the final DRC assessed. It is difficult to imagine a market in depreciation adjustments that is capable of being monitored and from which reliable adjustment factors can be derived. The US Appraisal Institute (2001) argues that: “the cost approach can be applied to older buildings given adequate data to measure depreciation” but “the difficulty of estimating depreciation in older properties may diminish the reliability of the cost approach in that context”. Certainly no research explains the nature of this market in depreciation or how it should be analysed to determine market-based depreciation adjustments. The cost approach is a direct consideration of the economic benefits and the period over which they might be enjoyed is not accurately captured in the value. A patented product may have been inexpensive to create but still have significant value because of the huge demand for product regardless of the selling price. Therefore, cost approach fails on the ground that economic benefits will be enjoyed are not directly considered to have significant affect on value

RESEARCH OBJECTIVES

1) Establishing reasons for the different values when using the Replacement Cost Method of Valuation and try to come up with ways to lessen the variance.

2) The study being the first of its kind hopes to set a ground work for a further in-depth study in the use of the DRC method of Valuation in Uganda

3) The research was mainly focused on variations in costs per unit area and not on the whole replacement cost method of valuation. The research was also focused on the case study, that is, valuation firms in Kampala city.

HYPOTHESIS

The use of different depreciation methods, rates and the lack of a centralized data source of cost estimates available to the valuers is the cause of the differing Costs per unit area in Kampala City.

MODEL

The use of different depreciation methods, rates and the lack of a centralized data source of cost estimates available to the valuers is the cause of the differing costs per unit area in Kampala City. International valuation standards state that; where there is sufficient market data to support the valuation, Market Value is derived. In other circumstances, where there is insufficient market data, the result will be Non-Market Value (IVSC, 2005). The replacement cost method is used in circumstances where there is insufficient market data, when use of the sales comparison or income capitalization method is not possible, and so the output will be a non-market value. However, when valuing specialized property where possible, the valuer develops land value, cost, and accumulated depreciation estimates from market information (IVSC, 2005: General Valuation Concepts and Principles, paragraph 8.2). In the cost approach, comparable data refer to the cost of building or development, and adjustments are made to account for differences in quantities, qualities, and utility. In addition, analysis of comparable land data and comparable depreciation estimates is undertaken (IVSC, 2005, International Valuation Guidance Note 1, paragraph 5.20.3). The cost method is mainly used on residential properties in Uganda and especially in Kampala city. This is as a result of insufficient market data on these properties and thus lack of comparisons and thus in this case the valuers can nevertheless use the sales comparison method of valuation nor the income capitalization method.

METHODOLOGY

The major elements that were executed in approaching the study consisted of planning, distributing questionnaires and scheduling of interviews. Planning included; a reconnaissance to map out the study areas while scheduling included organizing meetings with respondents and key informants. It was carried out using qualitative designs and quantitative designs. Qualitative designs were divided into descriptive, explanatory and evaluation designs. Interviews and questionnaires were utilized during the process of obtaining the opinions of key informants.

DATA SOURCES

The research was basically a case study of valuation firms in Kampala city. A deliberate simple random sampling procedure was also employed to (7) private real estate consultancy firms out of the (32) registered valuers with (25) valuation firms (ISU; 2008) whereby (3) valuers from each firm were interviewed and given a questionnaire to fill. The sample size was 21 valuers from 7 valuation firms out of 25 registered ones. 3 were chosen randomly to make 21 respondents. The primary data was collected from the case study using research instrument, that is, structured questionnaires. Twenty-one valuers from private firms were also interviewed on top of filing in the questionnaires to get the required information. Respondents were professional valuers from either government or private firms. Secondary data was obtained from of various valuation firms such as Allied Property Surveyors, East African Valuers and Surveyors, Associated Surveyors among others.

DATA ANALYSIS

Data Analysis, Quantitative data involved checking all field data to see whether they contained the required information, the results of the study was presented with the use of tables and charts to produce trends of the respondents. Techniques such as statistical description and tabulation were used for easy interpretation of the

quantitative data within the context of the study. Casual comparative educational search, which were part of the study, helped in attempting to identify a causative relationship between independent and dependant variables.

RESULTS AND DISCUSSIONS

The study covers responses from 21 respondents from 7 valuation firms in Kampala City out of 25 valuation firms. From each valuation firm 3 Valuers were selected randomly to answer the researcher's questionnaire.

Analysis of the valuers estimated market value for the property, which was under valuation.

As shown in the table below valuers came up with different market values due to several factors. The main difference was in the rates attached per unit area and this variation was because of the depreciation percentage used, the sources of cost information and the different assumptions. For the same property the valuers came up with the following market values.

Table1: Showing the estimated market values among different valuers.

Ranges Market values in shillings	No. of valuers	Percentage
120,000,000-140,000,000	6	29%
140,000,000-160,000,000	12	57%
160,000,000-180,000,000	3	14%

Source; Author's construct basing on the Field Work, April 2012

Analysis of the approaches used to come up with the cost in the Replacement Cost Method of Valuation.

From the survey carried out, it was realized that the Cost per Square Meter is most used in the Replacement Cost method of valuation as 21 out of 21 respondents responded to this approach as compared to the other approaches as shown below in the following table.

Table 2: Showing the most used approach in the Cost Method of Valuation

Approach	**Number of Responses**	**Percentage**
Quantity Surveying	None	0%
Unit-In-Place	None	0%
Cost Per Square Meter	21	100%
Cost Indexing	None	0%
Others	None	0%

Source; Author's construct basing on the Field Work, April 2012

Analysis of the use of Depreciation Factor in the Replacement Cost of Valuation

As shown in the table 3, all the respondents answered yes to the use of a certain percentage of depreciation in the method. This percentage is deducted from the final cost of the property before getting the final value. From the responses, it is evident that depreciation is an important factor when determining the market value in the Replacement Cost method of valuation. But the depreciation percentage varied from one valuer to another as shown in table 4 whereby 85% of the valuers used between 0%-20% depreciation percentage while 15% used between 20%-40% depreciation percentage and this was due to a number of factors such as; age of the property where by certain was attached per year, nature of the materials used, the purpose to which the property is put among other factors. Because of this, there was a variation in the rates used in costs per M^2.

Table 3: Showing the responses to the use of depreciation in the Method

Response	No. Of Respondents	Percentage
Yes	21	100%
No	None	0%

Source; Author's construct basing on the Field Work, April 2012

Table 4: Showing the depreciation percentage used on the same Property

Depreciation percentages	No. of Valuers	Percentage
0%-20%	18	85%
20%-40%	3	15%

Source; Author's construct basing on the Field Work, April 2012

Analysis of the information cost sources as used in the Replacement Cost of Valuation.

From the survey carried out on sources of cost information that are used in the Replacement Cost Method of valuation, It was realized that most valuers get their cost information from Quantity Surveyors, followed by Engineering firms/ Contractors, Architects, Real Estate developers. It was also found out that some valuers use a combination of the above sources such as Real Estate Developers and Contractors or Architects and Quantity Surveyors.

Table 5: Source of cost information used in the Replacement Cost of Valuation

 ISBN: 978-1-84219-840-7 .

Sources of cost Information	No. Of Respondents	Percentage
Quantity surveyors	15	72%
Engineering Firms/Contractors	4	14%
Real Estate Developers	2	10%
Others	1	4%

Source; Author's construct basing on Fieldwork, April 2012

Analysis of factors assumed during the computation of the Market value using the Replacement Cost Method of Valuation.

From the responses of the sampled out population, some factors were considered and some assumptions made before the computation of the market value when using the replacement cost method of valuation and they included the following; The materials used on the property under the valuation, the functional and economic obsolescence on the property, the age of the property, purpose of valuation, site works (the percentage varied from one valuer to another), the location of the property, the accommodation, the interest of the property, services available such as electricity and water mains, reduced area of say the garage or the covered veranda depreciation per year, highest and best use, prices of the building materials were from a common market.

CONCLUSIONS

From the above research findings, it is evident that the variations in the Cost per M^2 in the Replacement Cost Method of Valuation is due to a number of factors which range from the sources of cost information, the assumptions used in the valuation, the depreciation percentage attached, to the factors considered during the valuations. The above facts do vary from one valuer to another and this leads to a big difference in the rates that the valuers attach per M^2 and thus a huge variation in the end market value of the property that is under valuation. Variations in the estimation of the market value are expected since they are valuer opinions and are due to different factors considered nonetheless when using the replacement cost method of valuation; the estimated market values between different valuers are extensive. This is due to the variations in the costs per unit area because of; the cost information differences where a single and combinations of information sources were used. Depreciation and property age percentage differences with individual opinion and percentages were attached.

PRIVATE RETIREMENT VILLAGES: ANALYSIS OF RESIDENTS' NEEDS REGARDING SUSTAINABILITY AND WELLNESS

Prof. Andries C. Hauptfleisch[1] and Olive R.C. du Preez [2]

ABSTRACT

Private retirement villages (residents purchase residences and are personally liable for all expenses, not subsidised) have been in existence in South Africa for about three decades. There are successful as well as failed developments. The main problems are the lack of well-defined requirements regarding residents' preferences, sustainability and creation of wellness environments. These problems have been addressed in this research in order to add value to the decision-making process for both property developers and potential buyers (residents). A literature review was undertaken, but literature in this field is limited, and some new envisaged elements which might be of vital importance, have not been agreed upon or tried and tested. Extensive primary data was collected in a structured fashion. The research is ongoing and presently being extended. The study has revealed specific development and resident indicators based on resident decision criteria. Preliminary observations indicate that problems experienced are comparable to first world experiences. A noteworthy international USA research organisation states: "With one of the highest Gini co-efficients of inequality in the world, South Africa is in a certain sense a micro-cosmos in which aging can be studied – the aging world in one country".

Keywords: development directives, measurable preferences, residents' requirements.

INTRODUCTION, PROBLEM STATEMENT AND METHODOLOGY

Private retirement villages (residents purchase residence and are personally liable for all expenses, not subsidised) have been in existence in South Africa for about three decades. During this period, certain laws have been introduced and the format and ways of delivering retirement villages to the market have developed. As was to be expected there were successful as well as failed developments.

[1] ach@ecospan.co.za
[2] dupreezorc@ufs.ac.za

The **problem** addressed in this research is the lack of availability of quantitative and qualitative data based on the experiences and needs of residents of private retirement villages. The **objective** of this study is to create such data.

The research described in this report thus adds to the creation of a knowledge base that will contribute to the decision-making process of developers of retirement villages, as well as to the understanding and selection of retirement villages most suitable to satisfy individual prospective buyers' needs, thus creating directives for retirement village development.

The **methodology** used focuses on the creation of quantitative and qualitative data. A literature survey has been done to establish fundamental guidelines in support of the development of sustainable private retirement villages. Relevant literature is, however, very limited.

Quantified data regarding this specific field of study is a rare commodity. Empirical primary data generated during the research was obtained by means of questionnaires completed during structured meetings. A seminar, attended by the chairpersons and managers of retirement villages, was conducted to explore "democracy in design" information; in other words, which aspects of retirement villages function optimally, through to which might be regarded as failures.

Although this research has been conducted in South Africa, the methodology and content could be of value elsewhere. The terminology "retirement village", or "resort", or "estate", or "centre" is used synonymously in the "private retirement village" domain.

It is also noteworthy that private retirement villages in South Africa are presently almost exclusively populated by white South Africans (typical first world citizens). This is primarily ascribed to cultural differences in South Africa, where the black population traditionally has a well-developed "extended family" structure that takes care of family, particularly the young and the aged. This might change in the present-day democratic dispensation, also moving towards a more "westernised" society, set to benefit from this ongoing research.

It is to be noted that the terminology "trustees" and "body corporate" is often used synonymously. Legally the trustees are the persons, usually owner residents (not legally required) elected by the residents (they form/are the body corporate) as the "management committee" that in turn typically appoints a salaried manager – referred to as the manager of the village – to manage the village.

LITERATURE OVERVIEW

The research was conducted in a field about which very little has been published. "Sustainable private retirement villages" for all practical purposes have been in existence for less than three decades. Significant development has taken place in the last two decades. This time scale, with the resident population now having moved into average age groups around 80 years, is magnifying what is sustainable, and what is not. Very importantly, some new or envisaged elements, which might be crucial, have

not been agreed upon as yet, or tried and tested. "Sustainability" aspects needing serious consideration could be placed in a variety of compartments. One of the aspects covered in this study is health care from the perspective of "wellness" and "longevity". Financial sustainability, according to all indicators, is rapidly becoming a serious problem. The elderly simply cannot afford to sustain their lifestyle and personal care. Life-supporting services and goods are becoming more unaffordable as time passes, while needs are increasing all the time. Thus, sustainability of personal health needs, nutrition, services (utilities) such as electricity, water, sanitation, gas and general maintenance, is simply increasing beyond many of the elderly's means to afford.

Development guidelines, even if informal, in the traditional subsidised (by government and welfare organisations) "old age home" environment are well established, but these developments are fast becoming historic remnants with very little, if any, new projects being launched. The emphasis has thus shifted almost completely to private retirement villages. However, development guidelines are by no means entrenched and proven, making the developments repetitive experimental projects, unfortunately with serious and sometimes unscrupulous deficiencies entrenched. Some developments could even be classified as suffering from "criminal neglect". Prospective buyers are able to take comfort from the Consumer Protection Act (CPA) recently promulgated, which will assist them with recourse against blatant "developer non-performance". But, that still does not solve the problems associated with the creation of so-called retirement villages that are simply unsustainable. The establishment of a sustainable retirement village is well above the simple scoping of "design-it-sell-and-build-it". Enlightened retirees buying into retirement villages should hold typical hit-and-run developers accountable in terms of the CPA.

The following literature is relevant to the above:

(a) *Guide to Retirement Places* (McAlpine 2006). This guide deals with the physical location and provides concise notes on "retirement places". Although it summarises some elements, it makes no contribution to broadening the knowledge base about sustainability.

(b) *Retire Right* (Cameron 2004). This publication deals with various elements of personal and financial concerns of retirees. Although very little attention beyond financial advice is given to ensure that retirees buy into sustainable retirement villages, valuable warnings are, however, provided regarding investment risks, resale, levies, poor management, financial concerns, health care and other support. Cameron (2004:272) sounds a cautionary note: "The retirement village industry has not had a very satisfactory history in South Africa".

(c) The all-pervasive long-term affordability crisis that has to be addressed head-on is demonstrated by the shrinking purchasing power of the rand which has lost 90% of its purchasing power since 1991 (Human Action website, 2009).

(d) The bimonthly journal *Plus 50*, endorsed by two noteworthy organisations for older persons, namely GreyPower and the South African Confederation of Seniors Organisation respectively, makes important contributions towards the sustainable retirement debate. The following article references bear relevance to this research:

- Malan and Labuschagne (2009:24-27) published an article, following a symposium, with the title "Meaningful Aging – A Multi-disciplinary

Challenge". Important factors which they highlight address issues such as the behaviour patterns of aging related to biological, psychological and social processes. Social demographic issues like the erosion of traditional support structures, residential facilities, impoverishment, medical care, social and religious services, are highlighted. Reportedly already (2008) 7,5% of the South African population is older than 66, and is expected to have grown by 50% by 2021. Racial group poverty expressed as percentages of elderly persons is at 4% White; 19,5% Coloured; 6,6% Asian and very alarmingly at 56,2% Black.

- Van der Zel (2009:30-31) reports the following factors that influence longevity and health in an article titled "Creative and Positive Aging":
  - Genes
  - Nutrition
  - Lifestyle
  - Environment
  - Socio-economic status
  - Attitude and change
- Eckley (2009-2010:23-24) provides the following insights in an article: "Care of Older Persons":
  - Demographics are changing rapidly:
    - 3,7 million South Africans are older than 60, and this figure will have grown to over 6 million by 2030
    - The 80-years-and-older groups will have grown from 550 000 to 1,2 million by 2030
    - Children as a social support system is degrading for a variety of reasons
    - Mortality data indicates that older persons tend to die as a result of lifestyle diseases. Particular reference is made to inactivity; boredom; lack of "challenges" like working; and not taking charge of managing their lifestyle, health and aging.
    - There are presently about 480 independent retirement villages in South Africa that house approximately 89 000 people older than 50.
  - He identifies the following factors that promote successful aging:
    - Live and surround yourself with people that challenge you to still dream and work
    - Take care of your health
    - Take care of your energy sources, your psychological and spiritual well-being
    - Plan financially and live where the surroundings are conducive to your health
    - Ensure availability of security and health care
- Malan, Eckley and Bekker (2010:26-27) report the following, with specific reference to frail care centres, in their article "Frail-care Centres – Achilles Heel of Many Retirement Villages":
  - Developers of retirement villages incredibly often do not fulfil their undertaking to provide the "promised" frail care centre
  - Only about 2% of residents (ten years ago about 4%) actually do require the services of a frail care centre
  - Frail care centres are not economically viable below 25 fully occupied beds (absolute minimum), but the critical number should ideally be 40
  - The cost of running frail care centres is exorbitant and many residents simply cannot afford frail care if it is not subsidised

- Trustees of retirement villages are ill equipped to manage such centres
- Some frail care centres fall prey to obscure operators on contract basis
- Home-based care (in resident's own home) should be available in retirement villages

(e) Hoffman (2009:16-17) in an article "A Good but Affordable Old Age", reports that by 2030 half the population of Europe will be over the age of 50; by 2050 20% of the Asian/Pacific population will be over 60; China alone will have 300 million people over 60; and Sub-Sahara Africa 140 million over 60. The Oxford Institute of Ageing (University of Oxford) is actively studying global ageing demographics, also focusing on Africa. Hoffman (2009:17), senior research fellow at the institute, states: "With one of the highest Gini co-efficients of inequality in the world, South Africa is in a certain sense a micro-cosmos in which ageing can be studied – the ageing world in one country".

QUANTIFIED DATA PER GROUP

Primary data on the needs of residents in private retirement villages, or the shortcomings they experience, was collected in a structured fashion. Qualitative data to support this data was also collected for completeness. The questionnaires were created in table format with tickboxes for ease of completion, and respondents were given opportunities to add qualitative comments. Also see the section on Democracy in Design Workshop conducted in aid of further qualitative data collection. The actual data collected is comprehensive, but has been reduced in order to shorten the tables in this report. The data – based on either a 5-point Likert Scale, or presented as percentages, or as "yes" or "no" responses – reflects arithmetic means of the findings.

Respondents were categorised into two groups. Group 1 was easily identified, being the trustees of each retirement village. In some instances they preferred to provide a consensus-based questionnaire, as answers to some questions would be the same, for instance, "How many people reside in the village?". In the case of individual responses the arithmetic mean was used.

Group 2, representing the resident population, could not be selected by common statistical methodology as some residents are too old or frail to take part, or may have resided in the resort for too short a period of time. It was therefore concluded that the most suitable and informed responses from residents would be obtained from groups of 10 to 15 residents selected by the trustees as persons with representative views about their retirement village. Practically this methodology worked well.

This research is ongoing with surveys having been done in Pretoria, Bloemfontein and Knysna. Surveys in Johannesburg and Cape Town are being planned. The residents' questionnaire has been loosely divided into different sections as indicated in the presentation in the next section. Group A represents Pretoria (8 villages), Group B Bloemfontein (5 villages) and Group C Knysna (2 villages). The 15 resorts that have thus been surveyed house 1704 residents.

The data presented in section 3.1 was collected from the trustees and from the residents, section 3.2. The data has been reduced to the arithmetic mean per group,

ranked in order of preference (where applicable) for the dominant Group A. Corresponding results are given for Groups B and C.

	A	B	C
How many living units are there in your village?	127,2	97,48	99,50
How many living units in your estimation change hands every year in your retirement village?	6,09	3,70	6,50
How many residents are there in your village?	144,87	146,19	128,50
(calculated number of residents per unit)	1,14	1,50	1,29
What is the average age of the residents in your village?	81,03	78,81	76
How long (number of years) has your village been in existence?	17,34	14,29	17

It is apparently becoming more difficult for residents in retirement villages to afford frail care services. If you had the choice, when buying a housing unit in a new village, to pay about 5% more for your unit (which amount would be placed into a stabilisation fund by the developer), and to contribute about 8% of the reselling price of your unit to the stated stabilisation fund, would you be prepared to do it? Such contributions (which would be applicable to all living units in the village) would provide free, or very affordable frail care for those residents that might need it.

	A	B	C
Yes	77,1%	45%	100%
No	22,9%	55%	0%
What percentage (%) of your village residents requires long-term care, typically bedridden? In other words, of all the residents, which % will according to your estimation, and based on your experience, ever require such long-term care? Figures that are often quoted range between 3% and 5%, but it has not been fully researched.	4,57	6,50	3,50

It is apparently becoming more difficult for residents in retirement villages to afford frail care services. If you had the choice, when buying a housing unit in a new village, would you be prepared to pay about 5% more for your unit (which amount would be placed into a stabilisation fund by the developer), and to contribute about 8% of the reselling price of your unit to the stated stabilisation fund? Such contributions (which would be applicable to all the living units in the village) would ensure free, or very affordable, frail care services for residents that might need it. The stabilisation fund would be under the control of the management body/trustees of the village.

DEMOCRACY IN DESIGN WORKSHOP

The following data was collected during a morning workshop with the chairpersons and managers of villages in the Pretoria region. It is presented in the format of agenda points only. The preference responses of the participants (democratic evaluation of design responses) are available.

 ISBN: 978-1-84219-840-7 .

OBJECTIVE: To determine which aspects concerning the design and management of retirement villages function well, and which are insufficient. The following were investigated for this purpose:

1 Functionality of living units:
- 1.1 Floor layout
- 1.2 Private gardens
- 1.3 Home security

2 Functionality of the following areas:
- 2.1 Offices
- 2.2 Dining room
- 2.3 Lounges and halls
- 2.4 Kitchen
- 2.5 Garages, carports
- 2.6 Parking areas
- 2.7 Care facilities
- 2.8 Sub-acute facilities
- 2.9 Public areas and passages
- 2.10 Guest house/visitors' accommodation

3 Functionality of general services:
- 3.1 Energy efficiency
- 3.2 Garden water/borehole (well)
- 3.3 Premise perimeter security
- 3.4 Gate security
- 3.5 Catering
- 3.6 Intercom
- 3.7 Emergency call system
- 3.8 Gardens
- 3.9 Maintenance problems
- 3.10 Municipal services or the lack thereof

4 General management aspects:
- 4.1 Personnel requirements
- 4.2 Office installation and equipment
- 4.3 Financial management
- 4.4 Long-term financial viability/sources of additional funds
- 4.5 Residents' long-term affordability
- 4.6 Property insurance
- 4.7 Possibilities regarding co-operative management services and facilities

5 Developers' legacy:
- 5.1 Broken promises
- 5.2 Dysfunctional aspects
- 5.3 Financial aspects
- 5.4 Statements made with general consensus
- 5.5 Practical, sustainable and affordable health care in private retirement villages?
- 5.6 Architectural conformity
- 5.7 Turnaround strategies for existing retirement villages with deficiencies

SUMMARY AND CONCLUSIONS

This research is ongoing, and further knowledge should ensue. Preliminary observations indicate that the problems experienced by the target groups in this study (private, not subsidised retirement villages) are in many respects similar to those observed in the developed world. The latter, however, are experienced in countries where governmental and other forms of support are well entrenched, contrary to South Africa where practically no such support exists.

For practical reasons the overall data that emanated from this study has been condensed to the following:

5.1 Frail care and other forms of health care are top priorities for retirement village residents.

5.2 Personal safety and security rank equally high in the stated requirements of residents.
5.3 Other supporting services and general convenience aspects also rank high.
5.4 There seems to be little testimony that a need exists for "extravagant" services.
5.5 Although the researchers are of the opinion that a total wellness approach and provision of holistic wellness facilities and concepts are very important, there are few comparative elements in existing villages that could be evaluated and responded upon by residents. It could be argued that these represent the "new challenge" in creating a holistic environment that supports longevity, wellness and financial sustainability.
5.6 Provision of practical and functional facility designs that cater for the needs of the aged are regarded as non-negotiable.
5.7 Simplex/town house/bungalow accommodation is strongly preferred, but is less affordable.
5.8 Other than in support of churches and welfare organisations, no sound reasons could be found for retirees buying residences in life right villages rather than in villages where they will be title holders. It simply does not make sense to let the capital growth mainly accrue to the "developer".
5.9 There is strong support for efficient energy and other resources.
5.10 Residents are acutely aware of the affordability crisis that faces retirees and are strongly in favour of financial modelling that will promote long-term financial sustainability and care services for their villages.
5.11 Although the first leg of this study has been conducted in what is regarded as affluent areas in South Africa, more than half of the residents cannot afford more than the fixed village levy. Practically that means that if there is no suitable intervention to provide support for what is perceived to be necessary, and "nice-to-have" items, most residents cannot afford it. This affordability crisis, which is set to worsen, includes frail care and many other forms of care and wellness which could be classified as essential.
5.12 Although not quantified in this study, it is recommended that a grading system be introduced against which the quality of retirement villages could be measured to support the creation of sustainable and functional villages in general.
5.13 There are obvious concerns internationally that the world's ageing population could present a grave problem in future. However, many sources report in parallel to this perceived eminent affordability crisis regarding the care retirees require, that many ageing people do not necessarily prefer the route of "traditional retirement". There is sufficient testimony that staying active is healthy, reduces the risk of diseases such as Alzheimer's disease, and assists in bridging the affordability crisis. Some countries are already increasing the qualifying age for receiving retirement benefits in line with higher life expectancies and national affordability. The advent of an ageing population automatically becoming a social burden could perhaps be overstated. If ageing people remain economically active, even at a reduced pace, the problem of an ageing population could be relieved in many ways.
5.14 Available data indicates that the percentage of elderly people requiring frail care in later life is decreasing rapidly despite life expectancy increasing, which also indicates that the quality of life is improving in higher age groups. These observations are worthy of further research in order to test the general

assumption that the higher life expectancy of people will automatically create serious problems. That might only be true if the ageing population also requires dedicated health care for longer periods than previous generations. Obviously the increase in numbers of the elderly carries weight, but the exact impact with all factors attached to it requires more serious consideration and research than what is available at present.

SPATIO-TEMPORAL ANALYSIS OF COMMERCIAL REAL ESTATE AUCTIONS IN THE UK

Shane Patrick Galvin[1] and Dr. Charlotte Louise Leigh[2]

ABSTRACT

The commercial real estate market has witnessed a turbulent time over the past number of years as a result of the economic downturn. The auction room is an ever-present element of the market, acting as a barometer on which the wider marketplace gauges activity. Auction lots are inherently fixed in terms of space and time, with a fluctuating variable of cost. While research has been conducted to investigate the sustainability and viability of auctions, the geographic component through time has yet to be explored. This paper explores how commercial real estate auction data from the UK can be fused with other forms of geographic information and analysed in a spatio-temporal context using GIS techniques. The paper concludes by considering the impact that the geographical distribution of commercial real estate auction lots has on the sustainability of the auction market.

Keywords: auctions, commercial real estate, GIS, spatial analysis.

INTRODUCTION

The turmoil experienced by the economic downturn has had a deep impact across many sectors of the economy and the Commercial Real Estate Market is no different. The past number of years has been some of the most challenging for the industry as its tries to remain buoyant in a subdued marketplace. The auction room as a fountain of liquidity in this market offers transparency of transactions, as well as a window into market activity levels. Total commercial auction sales for 2010 were £1,000,739,341 reflecting only 43% of the 2007 total of £2,314,037,767 (EIG, 2007-2010). This has led to a deep impact in the industry with many auction houses realigning, retreating or being made redundant.

The use of simple quantitative techniques in the analysis of commercial real estate auctions and the property market in general is in wide spread use. In a time of uncertainty for the market amongst unprecedented economic challenges, the analysis of the data using an alternative technique may lead to the exploration of some interesting findings, which can perhaps shed light on the current performance and future direction of the market.

LITERATURE REVIEW

Relevant academic literature on real estate auctions in the UK is severely limited and confined in the main to professional publications. There are a number of papers that flirt with the auction topic but not wholly in the context of real estate, let alone commercial real estate. It is this finding in itself that has necessitated the need for further research in to the UK real estate auction market. The author has conducted research in this area for a number of years and previous papers by Galvin et al. (2009, 2010) have discussed the Commercial Real Estate Auction Market in a variety of approaches including sustainability and viability. This paper is utilising a new approach in analysing auction data. While the techniques are not new in entirety, their application to real estate data is limited and non-existent regarding auction data.

The use of Geographical Information Systems (GIS) for analysing spatial distributions of geo-coded data has been widespread in the fields of crime (Zhong H. et al., 2011) (Chainey & Ratcliffe 2005), health (Bell et al. 2006; Widener et al., 2012), urban planning and ecology but there is little evidence to suggest that GIS has been employed for the analysis of commerical property auctions. A concise definition of GIS is put forward by Burrough and McDonnel (1998), GIS is defined as "a powerful set of tools for collecting, storing, retrieving at will, transforming and displaying spatial data from the real world for a particular set of purposes". GIS provides the ideal means to store, manipulate, analyse and visualise the data collected using these techniques, especially when considering the spatially varying nature of the data proposed for commercial real estate auctions. The application of GIS in real estate research is not a new concept as Wyatt (1996) explored its use as a tool for property valuation. While commercial real estate auctions have not been analysed in terms of a statistical geographical context, livestock auctions have been examined by region and catchment area (Saizen et al., 2010; Wright, et. al., 2002) and viability explored.

Point Pattern Analysis which is the spatial analysis of geo-coded point events or phenomena has been widely exploited in many domains. A variety of methods built on spatial statistics have been developed for identifying 'hot spots' or clusters of point events. Kernel Density Estimation (KDE) is an established and accepted 'hotspot' technique for the analysis of point data; however it is under exploited in the area of real estate auction analysis. KDE is a grid raster based type of analysis and works by fitting a smoothly curved continuous surface over each point event. Subsequently grid cells containing no points have interpolated values. The density at each output raster cell is calculated by adding the values of all the kernel surfaces where they overlay the raster cell centre. The kernel function is based on the quadratic kernel function described in Silverman (1986, p. 76, equation 4.5). KDE is one of the most popular methods to be used for analysing a point distribution (Bailey and Gatrell, 1995) (Silverman, 1986). Some KDE tools for point and line pattern analysis are available in commercial GIS software such as Spatial Analyst Extension (ArcGIS) and more specific spatial statistical analysis software, such as CrimeStat (Levine, 2004).

Thematic mapping is a GIS technique used to visualise and analyse aggregated geographic data that is typically contained using census or other polygon boundaries. It is useful for obtaining a general overview of spatial distributions. Caution needs to be taken when deciding upon the chosen boundaries. For the purpose of this paper UK Local Authority boundaries have been used due to the large geographic extent of the auction dataset.

Spatio-Temporal analysis lends itself particularly well to commercial property auctions due to adding the dynamic of 'time' in a spatial context, which in such a changing market place can not be omitted from the model. The use of Spatio-Temporal Analysis in a real estate context although a recent application, has been previously utilised in papers mainly focusing on China's booming economic growth and related urban sprawl (Seto & Fragkias 2005).

METHODOLOGY

The data was obtained from the Essential Information Group (EIG) which specialises in providing data for the real estate auction industry. A dataset was distributed at the completion of each auction which contained all the information which then had to be processed in excel and geo-coded using separate Postcode data which is the essential link when mapping the data in a GIS. When only the first part of the postcode is given for example, CF38, then the location plotted will be the centriod of that postcode area. The mid 2009 - 2010 data contained the full postcode for the auction properties which enabled a level of far greater accuracy when plotting the properties.

The data supplied was from auctions that sold mainly commercial real estate during the time period analysed. During the downturn in the market, some auction firms which traditionally traded exclusively in residential or commercial auctions sold both commercial and residential properties in their auctions to boost their auction catalogue. Therefore firms chosen were done so by mainly selling but not exclusively, commercial investments. The breath of possibilities for the use of this technique and the varying data is discussed in further research.

All data storage, manipulation and analyses were processed using the leading commercial GIS package ESRI ArcGIS 10. The two main techniques employed for the analyses were thematic mapping using quartile classifications and the spatial analytical technique of hotspot analysis using Kernel Density Estimation (KDE). Chainey et al. (2008) compared KDE to other methods using a prediction accuracy index and concluded that KDE consistently produced the best hotspot maps for predicting future events. For the purpose of this paper a hotspot can be defined as a geographical area of higher than average occurring real estate auction lots (sold or unsold).

During the time frame of 3 years that was used (2008-2010) the auction industry underwent some changes and takeovers. Firms closed and other firms taking over whole auction teams for rivals. Therefore the firms active within the market over the 3 year sample are not consistent, although many are reincarnations.

ANALYSIS & DISCUSSION

The data utilised in the research was a large sample taken from the leading commercial auction houses in the UK. Table 1 outlines the distribution of auction lots amongst the leading commercial real estate auctioneers. The commercial real estate auction market in the UK is dominated by about 10 firms, and of those Allsop Commercial, having the largest market share increasing from 35% in 2008 to 45% in 2010. The table also identifies the firms that have changed over this short time span, illustrating the flux that the industry in currently experiencing. The majority of these firms hold residence in London from which they offer a national service.

 ISBN: 978-1-84219-840-7 .

Table 1 - Auction Lots by Auctioneer

Auctioneer	**2008**	**2009**	**2010**
Acuitus	0	0	188
Allsop Commercial	697	745	773
Cannon Capital	0	0	61
Colliers CRE	340	128	72
Colliers International	0	0	30
Cushman Wakefield	341	238	183
Erinaceous	65	0	0
Jones Lang LaSalle	292	231	49
King Surge	75	188	113
Lambert Smith Hampton	0	0	56
Savilles Commercial	171	104	157
Total	1981	1634	1682

Table 2 illustrates the status of lots that went to auction. Various rationales would have led to the possible outcomes that are achievable when a property goes to auction and many factors influence bidding activity. For example, on the lots that failed to usher a single bid, there could be a multitude of reasons why this was so, from missing information in the legal pack, the condition of the property or the conditions of sale. For the purpose of this research the main focus will be on the spatial distribution of sold and unsold lots. Between 2008 and 2010, the amount of commercial lots that went to auction dropped by 17%. However, during that time the combined amount of sold and unsold lots remained stable at 79% of lots offered, with the sold fluxuating between 50-55% and unsold 23-29%.

Table 2 - Status of Lots at Auction

Status	**2008**	**2009**	**2010**
Total Auction Lots	1981	1634	1682
Conditional Sale	1	0	0
No Bids	42	18	15
Refer to Auctioneer	12	2	1
Sold	999	904	862
Sold Post	43	26	21
Sold Prior	107	163	127
Unsold	578	388	474
Withdrawn	199	133	182

 ISBN: 978-1-84219-840-7 .

Spatio-temporal Analysis

Figure 1 shows the hotspot analysis of sold commercial real estate auction activity in the UK from 2008 to 2010. Although the national auction houses that dominate the market operate out of London, the spatial distribution illustrates that the properties are widely located across the UK. It is obvious for each year that there is a hotspot cluster of sold commercial properties present in London, however it is clear from the maps that there has been a definite shift in distribution. In 2008 it is evident that there are many more hotspot locations other than London, with similar density being achieved in South Wales, the Midlands and the North West. This is a diminished case in 2009 and by 2010 it is clear that the majority of sold commercial properties were centralised in the Greater London area. When using the KDE technique to examine unsold lots (Figure 2) relative to the sold lots, this trend remains relatively consistent over the 2008-09. However, in 2010 London clearly was the investment market of choice reflecting its status at the hotbed of the UK economy. Furthermore, the geographic concentration of sold and unsold lots for 2008 is relative, 2009 could be classified as a transitional year, where there are slightly more clusters of unsold lots to sold lots. The 2010 map illustrates that there are more hotspots of unsold commercial property lots than sold lots.

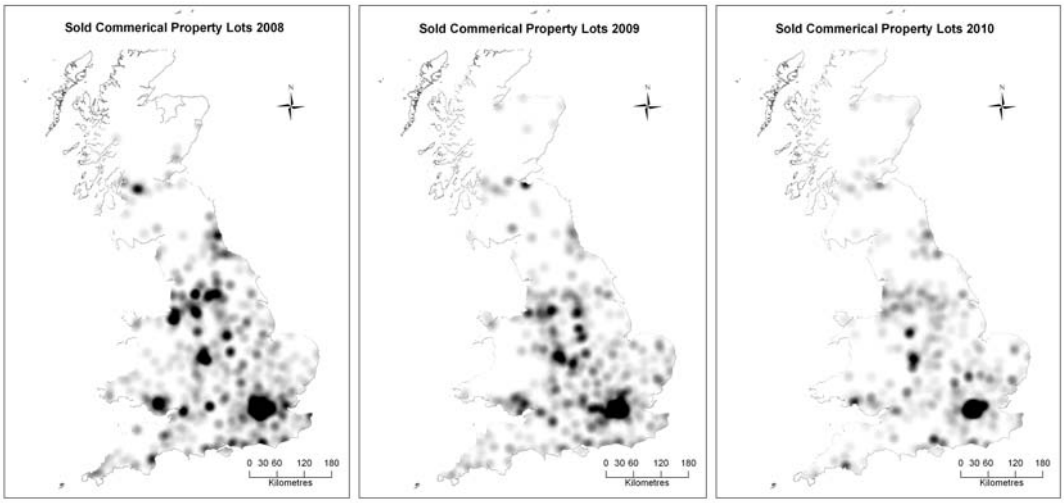

Figure 1 KDE Sold Commercial Property Lots 2008-2010

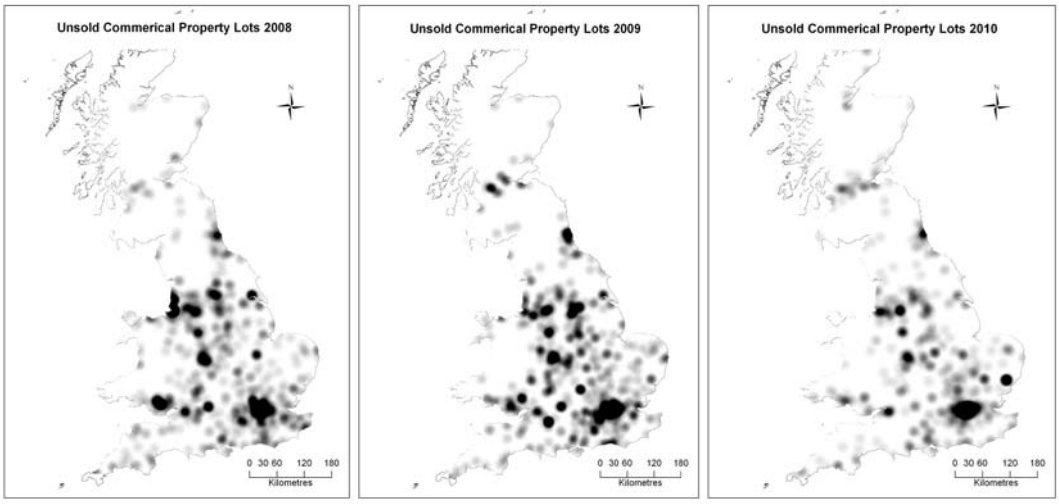

Figure 2 KDE Unsold Commercial Property Lots 2008-2010

Thematic Mapping by Local Authority

While KDE has successfully identified hotspot clusters of sold and unsold commercial property lots in the UK, the maps are somewhat dominated by the quantity of lots available in Greater London, therefore it is important to use thematic mapping to gauge an understanding of the distribution at Local Authority (LA) level. As London is divided into much smaller LA boundaries, it is evident that there are some interesting findings in other parts of the UK (Figure 3). For example, in 2008 featuring in the top 10 rank of LAs with the most sold commercial real estate lots, Greater London LAs only appeared in 4 instances, with Rhondda Cynon Taff containing the most sold commercial property lots in the UK. Other featured LAs included Ellesmere Port and Neston (Cheshire), Birmingham, Leeds and Swindon. By 2010 sold commercial property lots were most certainly centralised in London, with 7 London LAs featuring in the top 10 rank of areas. The upper quartile of unsold lots (Figure 4) featured LAs outside of the Greater London area such Ipswich (England), Swansea (Wales) and Highlands (Scotland) illustrating a more even distribution.

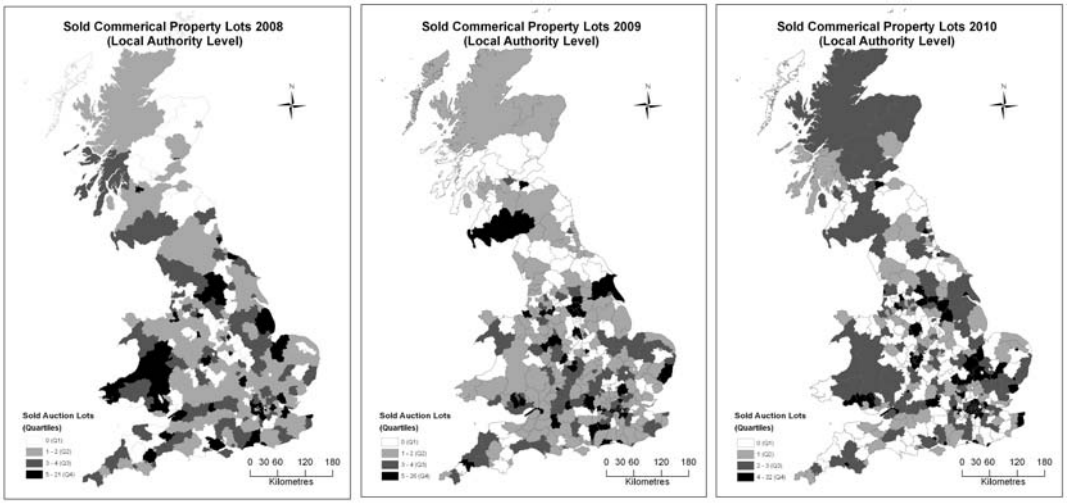

Figure 3 Thematic Mapping Sold Commercial Property Lots 2008-2010

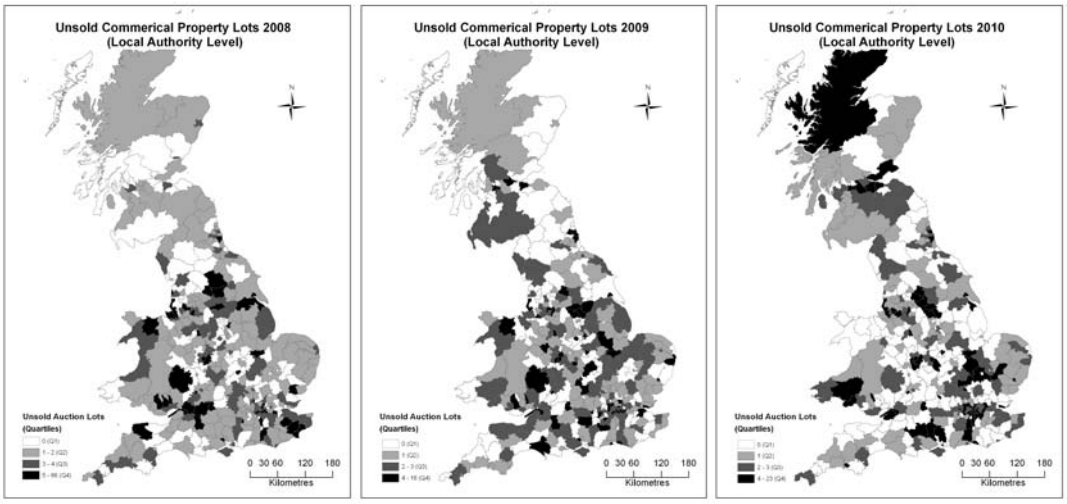

Figure 4 Thematic Mapping Sold Commercial Property Lots 2008-2010

CONCLUSION

This research has clearly demonstrated the potential of using GIS and Spatial Analysis techniques for the exploration of the geographic distribution of commercial real estate auctions. Location and time being the essential elements in the valuation of real estate, it is a logical progression to integrate spatio-temporal mapping into the knowledge pool of information available in the market. In an ever-changing market such analysis is crucial in predicting future trends and focus, for vendors, purchasers and the auctioneers themselves. As the market has changed over the 3 year period, with a decrease in lots offered, there was an increasing lack of demand for properties outside of the Greater London area. This is reflective of the concentration of investment in the capital, while highlighting investors caution to investing outside of the central economic hub in an uncertain market and economic climate. A sustainable auction market needs an increase in investor demand beyond the Greater London area.

Future research will include using other innovative GIS techniques to fully interrogate the drivers of the changing auction market place such as geographic regression and the Getis-Ord GI* statistic. Additional analysis and mapping could be undertaken by investigating tranaction yields and price, auction lot catergorisation by type (retail, industrial & office) and classification (prime, secondary & tertiary). This would give more in-depth understanding of the sub-categories within the market and their performance to market stakeholders.

A NEED TO INNOVATE THE DUTCH BUILDING REGULATION

Dr.N.P.M. Scholten, PhD [1], R. de Wildt, MSc, FRICS [2] and Prof. A.C.W.M. Vrouwenvelder[3]

[1] *ERB Foundation Expertcentre Regulations in Building, Motorenweg 5M, NL-2623 CR DELFT, the Netherlands*

[3] *TNO, P.O. Box 49 NL-2600 AA DELFT, the Netherlands*

ABSTRACT

Increasing dissatisfaction with the regulatory burden, with the (municipal) system of quality assurance and the general loss of knowledge and experience on operational levels led to two Governmental Committees who presented in 2008 their conclusions and proposals. For instance private certification of the building permit procedure, and to concentrate the knowledge of municipalities in regional intermunicipal bodies. These proposals will however not change fundamentally the attitudes and behaviour of the parties in the building process, owners and users of works. Experiments since show only increased costs and liability.
Also more fundamental questions were raised about quality assurance and responsibility in a market driven construction sector. Should the national building regulation set a minimum standard for all relevant aspects because of market imperfections? Or is self regulation feasible. And if so, will it be effective without supervision by an authority?
In 2011 three new studies were commissioned by the Government to address perceived problems. Two subjects were the economic effects of changed regulations, the and the cost effectiveness of existing building regulations. The third integral study, executed by Foundation Expertcentre Regulations in Building (ERB) was based on the weaknesses in the knowledge circle of the building sector. It led to proposals to redefine responsibility and liability for all parties.
This study states that by an effort of yearly € 100 million, unnecessary costs up to € 1 billion can be avoided and a real quality push will take place in the building and real estate markets.
This paper discusses the three studies and the given proposals.

Keywords: deregulation, education, liability, system innovation.

INTRODUCTION

The Dutch Building Decree has been under discussion for decades. Clear building rules and regulations form an important, even an essential link between building

[1] n.scholten@bouwregelwerk.org
[2] Rob.de.Wildt@rigo.nl
[3] ton.vrouwenvelder@tno.nl

practice and society, aiming primarily at the availability of safe, healthy, usable and sustainable buildings. How effective building rules and regulations are depends largely on their practical applicability, costs and the extent in which they allow building innovations.

With its Building Decree 1992 Dutch legislation took an important first step a system that meets these objectives. As opposed to the traditional building regulations, the Building Decree does not prescribe in detail how to build, but indicates, the required performance. This system leaves space for the introduction and application of fresh, innovative solutions.

Now, almost twenty years later, the building regulations have been changed three times fundamentally, initiated by deregulation initiatives. The last one is more and more based on the idea that governmental regulation can be skipped in the belief that market forces will ensure a good performance, in the whole building sector, also for the long run.

Although the Building Decree has proven to be successful in many aspects, various problems have emerged which appear to be structural in origin.

ERB published its first, overall analysis and vision (Scholten, et al.2008) in 2009. One of its conclusions was that the end user – who, as the owner of a building, is legally accountable for it to meet the rules and regulations set – is represented too feebly in the building process, and often does not even play any role at all in the decision-making, especially not in the formulation of regulations. Because of this, the end user could in practice become the loser. As a result ERB assigned a group of experts and scientists to further investigate this issue and to come with a remedy to this undesirable situation.

Other conclusions were that in the public and private sectors two separated circuits of knowledge development took place, and that the building regulations in their present form insufficiently warrants that public objectives are realized.

In the end of 2011 a quick scan study was realized commissioned by the Government:

to describe the desired change in public and private roles of involved parties in the building process and in the management and maintenance of real estate.

to sketch a robust future picture of the development and content of the building regulations and the role of the different parties in that process by focusing on the protection of the non professional end-user.

to change the building control process and the process of assessment of the performance of existing stock to strengthen the position of the end-user in such a way that the realized performance fulfills the regulations and that at the transfer of real estate by owner or tenants the performance will be transparent and guaranteed.

THE PRESENT SYSTEM

As a reaction to the abominable bad housing of city immigrants in the second half of the 19th century the Netherlands introduced the Housing Act in 1901. From then the municipalities were responsible for the drawing up and enforcement of regulations in the form of local building codes. In the 20s and 30s of the 20th century, the Housing Act advanced the construction of good - and still attractive - dwellings.

After World War II building contractors and developers operated more and more nationwide. They were confronted with all kinds of different and inconsistent local regulations. In order to to rationalize the building process, countrywide uniformity was required. As a first move the Association of Dutch Municipalities issued the

 ISBN: 978-1-84219-840-7 .

Model Building Bylaw. But many municipalities kept adhering to their own building regulations and the call for national uniformity became stronger.
In 1982 the Lubbers-1 cabinet took the initiative that finally resulted in the 1992 Building Decree. The Housing Act stated that from then on municipalities, fire brigades and utility companies were no longer allowed to issue regulations supplementary to or deviating from the Building Decree.
This first Building Decree had a completely different structure. In the old system, the building regulations described specific solutions to many regularly occurring construction problems; innovative solutions were formally not allowed. As the Building Decree states the performance required of complete buildings, constructors could apply both existing standard solutions as well as new, equivalent or better .
Between 1992 and 1998 the government worked on a second edition of the Building Decree which was never enforced. In 2003, the presentation form of the Building Decree was changed at the request of the market into the so-called tables legislation. However, the Dutch government simultaneously introduced a new modeling principle of works that was not in conformity with the experience of neither the construction partners nor citizens.
On April 1st of 2012 a revised Building Decree 2012 came into force after a long development struggle. It integrated elements of Building Decree 2003, of 418 municipal building bylaws, the Decree on fire safety structures in use and the Decree on road tunnels. The political goal was to reduce more than 25% of the volume of all clauses and to diminish the freedom of local authorities to decide about exemption of requirements for renovations.
Since its publication in 1991, the Building Decree has now been changed 31 times. Often miner changes and two mayor revisions as described above.
The Building Decree does not cover the whole spectrum of regulations relevant to building. For specific buildings and safety and healthy rules, the specialised Ministries published their own technical regulations.
Besides these, EU regulations for construction products were introduced, due to the required free movement of goods and reduction of use of energy.
In order to reduce the burden of too many regulations and organisational fragmentation the Dutch government recently decided to implement three important measures:

a) one ‘environmental counter’ for the dealing with ‘environmental’ related permits (the General Physical Environmental Rights Act), but at the start of the Government Rutte I in 2010 a more rigid law reconstruction in the Environmental area is foreseen;
b) bundle all knowledge at the enforcement level by combining the responsible local services at regional level, implementing the advice of the Mans Committee (VROM 2008);
c) organize the fire departments regionally (Act on Safety Regions).

A NECESSARY REVIEW OF THE SYSTEM

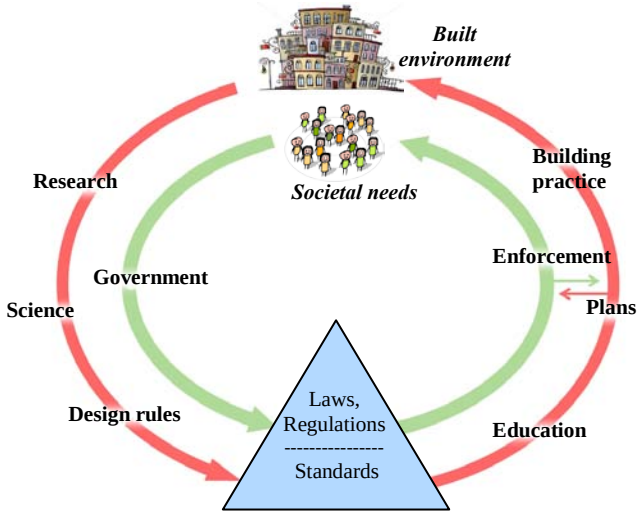
The three recent measures are administrative and organizational answers to problems that are rooted deeper. Both, the public legislation and the privately developed system of Building Standards form part of a knowledge system that is necessary to realize and manage safe, healthy and sustainable buildings. That system should function properly, which is not the case at present. Regulation is more effective, when it is developed in line with this knowledge system. Everybody involved in buildings,

construction and its management, must be able to properly understand, interpret and apply the regulations.

This knowledge system should also facilitate possible adaptations and the development of new regulations. Of course, these regulations should comply with the practice of design, construction and use. Lessons learned from practice should in turn lead to research and improved regulation. Attention must be paid to the transfer of knowledge as well as to the restructuring of the regulations.

The cycle of knowledge

The skills of designing and constructing good and reliable buildings are rooted in building science. This has largely developed empirically and is continually developing further. With a view to practical applications, scientific knowledge has been incorporated in design regulations, governmental rules and regulations and Standards. We may assume that buildings are sufficiently safe, healthy and sustainable when architects adhere to these regulations. Naturally, the same counts for owners and users when managing and running their real estate. Should they not do so, we ought to change the regulations or stimulate people's adherence to the regulations. Occasionally, or in case of technological innovations, people should be able to deviate from the details in the regulations without necessarily endangering safety, health or sustainability. We have depicted the process outlined here as a circle of knowledge (see figure 1):



The *public* learning track (green): public requirements are translated into rules and regulations through legislation, enforced according to public law by means of a licensing system, general terms and conditions, or sanctions recorded in the Housing Act, Municipalities Act and the Provisions of administrative law;
The *private* learning track (red) runs from research and science, through technical specifications and known solutions which are transferred in training programs, leading to professional practice. Some of these specifications and agreements have been laid down in Standards and assessment guidelines.

Figure 1. Knowledge circle (Scholten, et al. 2010)

Building regulations combine the two tracks to become a crossroads. Knowledge of Standards and their background is also essential for enforcement, and knowledge of rules and regulations is just as important for education and training programs.
On the basis of the ideal model we are able to clearly illustrate the practice related hitches. Figure 2 charts these hitches.

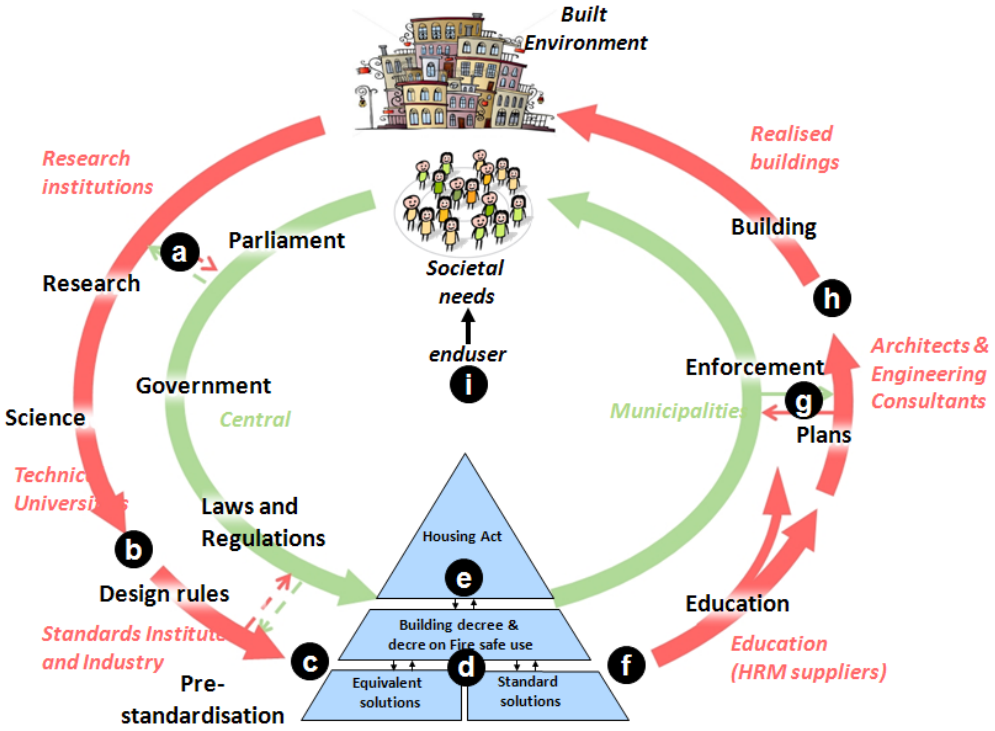


Figure 2. Hitches in the knowledge circle (Scholten, et al. 2010)

The first general problem is that the various actors in the private-law circle of learning work totally independently from each other. Universities, research institutes, schools for professional training, commissioning clients, designers, engineering consultants, building contractors, fitters, suppliers and consumer representatives, they all adhere their own policies, focusing specifically on their direct self-interests, and without much coherence.

The next problem is caused by both a highly fragmented sector and the fact that not a single party individually obtains a competitive advantage from investing in the development of communication systems and therefore chooses not do so, however these systems are necessary to structure and improve mutual understanding in the sector. Centralised communication systems are no–one's priority, and no 'central market superintendent' exists who could organise this.

And then there are other factors. We refer to the characters in the black dots of figure 2, described in (Scholten, et al. 2010). We summarize the importing ones. In order to make public-law rules and regulations and private- law agreements match, the two learning tracks on the left-hand side should be linked up with each other. At present there is no interaction whatsoever.
Standardisation must be based on research. The performance requirements must be based on measurement, determination or calculation methods. At present, unfortunately, many terms and conditions, and Standards are insufficiently based on science. Due to the lack of proper financing, universities have little interest in the methodology and modeling necessary to formulate rules and regulations. The technological institutions such as TNO (Netherlands Organization for Applied Scientific Research) largely depend on occasional commissions from the government and industries. This is the reason why they miss the long-term stamina necessary for the development of scientifically sound rules and regulations or Standards.

 ISBN: 978-1-84219-840-7 .

The knowledge on which the development of regulations and Standards is based has been insufficiently recorded and managed in the present system. After the successful completion of a regulatory project, everybody should be able to easily find the relevant background information with a view to clear objectives and an unambiguous interpretation, and support of the equivalence of possible, fresh solutions. Now, this knowledge seems to ebb away to such an extent that even the responsible bodies themselves do not always understand their regulations.

Individual private-law regulations, such as Standards, have been drawn up based on different disciplinary backgrounds, for instance: by constructors, experts in fire safety, and those in building physics or materials specialists; also European standards use other words than the Dutch regulator; so these regulations do not match nicely. One result is a differing and inconsistent use of language. As the Building Decree (2012) refers to such regulations, unavoidable inconsistencies develop in legislation. The legislator's use of language is not that of the standardization committees, while neither speaks the language of the man on the building site the performance approach requires a level of abstract thinking which is not used on the shop floor; specialists with secondary education only understand problems by way of practical solutions. Would regulation be consistent and translated in shop floor language, the correct application of regulations would improve greatly.

The scope of application of building regulations should probably be extended. According to the original Housing Act, building rules and regulations were meant for the safety and health of the users of a building. Later, as an effect of these, regulations were added with a view to its usability and energy efficiency, later followed by accessibility and sustainability and by April 2012 also by fire safe use, demolition, safe maintenance en sustainability. Up to now, economic and cultural aspects and the prevention of criminality have been included only to a small degree. However, the regulations which have to promote the well-being of construction and aid-workers, such as firemen, have been laid down in the Law on Conditions at the Workplace; one can only find them implicitly in building regulations. Although the construction industry is one of the most dangerous, unhealthy and energy-consuming economic sectors. Surely, a building application or process should not only meet the building regulations, but also satisfy the Commodities Act: elevators and appliances), the Environmental Management Act, the Nuclear Power Act: ionization alarm, Police Act, Records Act and the Law on Conditions at the Workplace. With such complexity it is not surprising that people experience regulations related stress.

Rules and regulations only form a minor part of the curricula in secondary and tertiary professional education and universities. This creates an important gap in knowledge both within industries and within law enforcement organizations of the government. It seems as if people no longer see how closely the administrative and building laws as well as technical regulations are connected.

Preventive assessment to meet public law is done only in the design stage of a building. So, one cannot be sure that buildings realized actually comply with the relevant regulations.

In today's building processes the end user, often the owner (to be) of a building, hardly plays a role. As the end users often are parties differing from the commissioners of buildings (the developers and investors), their specific interests will generally be insufficiently represented in the design and construction stages. Therefore they will have to rely on the public rules and regulations to protect their interests. Many commissioners completely ignore many kinds of aspects that, for a society, are desirable and beneficial in the long run – think of the accessibility of

 ISBN: 978-1-84219-840-7 .

buildings for persons with functional limitations, or the adaptability to various other uses of a building. If these requirements have been carefully dealt with in their design and construction, the layout of buildings might have to convert less often, the risk of vacancy might be lower, and early demolition due to their being unfit for purpose might be scarcer. The only way in which to realize this societal goal is for the government to list minimum regulations and enforce them.

PROPOSALS FOR SYSTEM INNOVATION

Starting point is the enforcement of regulations whose societal usefulness has been proven. To diminish the burden of overregulation we can for each aspect present the rules on three different assessment levels. That is needed for three areas of application: the newly built buildings (construction works); the renovation/-refurbishment/transformation and the existing stock. For each of these areas an own set of objectives and rules might be necessary and logical.

Starting point should be for all sub aspects that the objectives of regulation are quite clear and are discussed between all parties concerned, not in the least with the end-users, and are formulated clear and concise. This is functionally a governmental task and should be taken up before anything else.

The translation of the objectives into regulation for constructions and buildings is clearly a task of the professional market parties.

A first assessment level is meant for easy elaboration of ‘standard solutions’. We assume that possibly 80% of the building plans or existing buildings are or consist predominantly of ‘standard solutions’. The middle level more or less resembles or would be an improved Building Decree 2012, that focuses on performance. The proposed third level concerns building works in which unconventional and innovative solutions are to be implemented, using a probabilistic approach in assessment.

Should an applicant differ in opinion on whether a proposal meets the level of the standard solutions or the level of the ordinary assessment according to the performance requirements of the Building Decree, the third level would then provide the possibility of assessment according to the objectives regarding safety, health, usefulness, energy efficiency and sustainability. In that way discussions with regard to technical content need not end in judicial disputes.

For many people the introduction of these two new levels will substantially diminish the burden of overregulation. By standard solutions one could implement the greatly simplified regulations instead of those of the Building Decree 2012. While, at the third level, one can judge innovations against the the formulated objectives. outside the known territory of solutions and construction rules.

It is in no-one’s interest to enforce regulation that is not well understood. The three level structure will improve the practical use of the regulation and will promote the legislators real objectives: the enforcement of safety, health, usefulness, energy efficiency and sustainability. That is how regulation is linked with objectives.

Because of the lack of knowledge the development of the objectives and structure of three levels and three areas of application should be prepared by a "Knowledge Institution", financed by the Government and the market parties together (PPP). In this institution the few experts there are at the moment will join forces to organize and prepare the outline of the objectives and to oversee the development and elaboration of the structure of regulation. Within the Knowledge Institution all data behind the regulations will be concentrated and stored, accessible for all parties concerned, for now and in the future.

ERB proposes also to improve the safeguarding of the regulation related knowledge. Together with all those involved in the building process - from science, knowledge institutes, education, architects and engineering consultants, to the actual builders and the real estate sector - we must try and form a secure chain of knowledge with properly linked up sub processes. Only with a properly functioning knowledge system can we rely on the building sector to meet the objectives which we may expect from it. The foreseen Knowledge Institution will form the focal point.
Procedural innovations are required. We need to attune the three assessment levels. The accepted standard solutions will be assessed according to the performance requirements as laid down in the second category and the question whether the performance requirements themselves meet the objectives set, is answered by means of the risks approach which we will apply in the third category.
The elements which the three levels share at a generic level: objectives, risks models, user models, functional models and performance requirements, prepared by the Knowledge Institution and discussed with all parties concerned.
The general structure of rules and regulations as presented below, in figure 3, has been depicted in the form of the grey triangle. This part of the structure ensures that the system remains consistent, also when objectives change or new objectives, rules or constructions are introduced. The parts relevant to applicants and assessors are represented in blue.

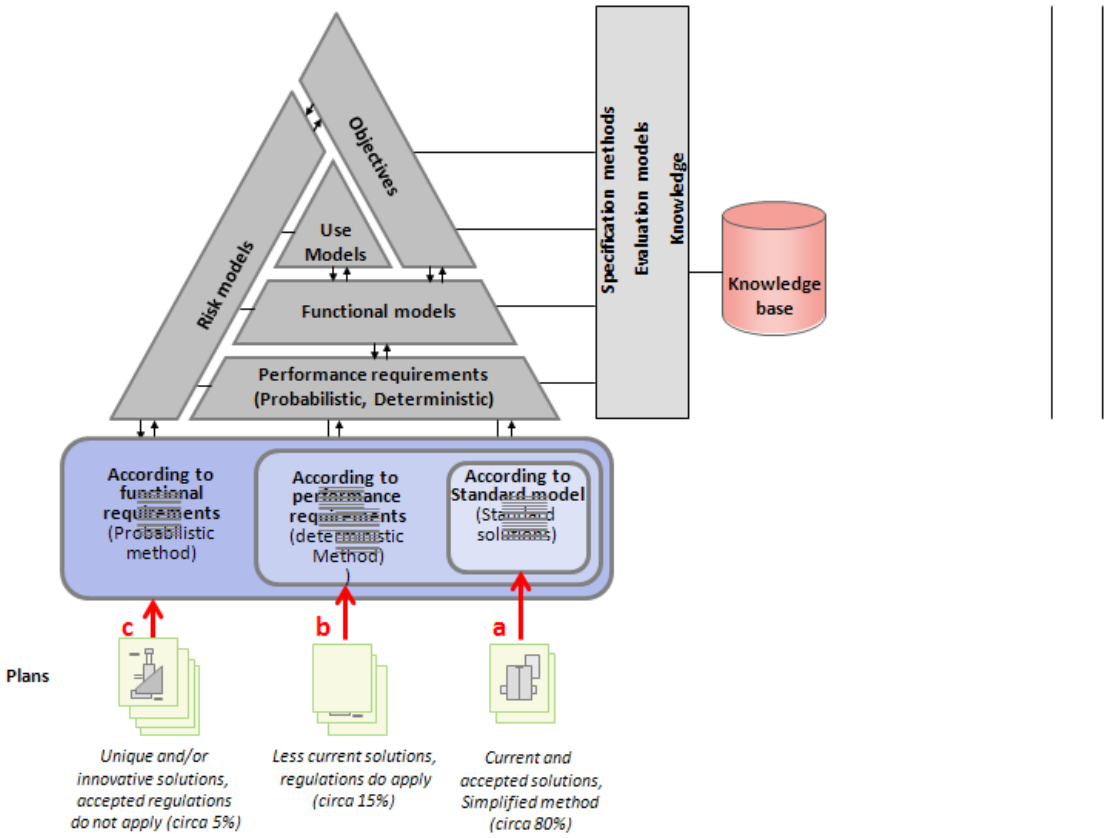

Figure 3. Presentation of the firm structure of development of building regulations (Scholten, et al. 2010)

 ISBN: 978-1-84219-840-7 .

Explanation of captions used in figure 3.

Objectives. Regulation must be the outcome of a single coherent system of objectives. These objectives are the foundation of the regulatory system and should be well defined and written down.
Risks models. Absolute guaranties for safety, health and sustainability cannot be given. Objectives always deal with *possibilities* and *risks*. They deal with the possibility of collapse, the risk of permanent physical injury or death, and the possibility of environmental damage. The present regulation often provides strictly limited values for these possibilities and risks. Does it mean that exceeding these limit values immediately results in unsafe and unhealthy situations or limited sustainability? Depending on varying circumstances or the use expected, a building may still, in an acceptable way, meet the objectives laid down.
That is why we will again have to standardize the whole system of regulations, standards and limit values according to the objectives using risks models and the theory of probability. These models must become an integral part of the regulatory system. This too would greatly simplify regulation.
User models. We can only translate objectives into specifications for buildings if we also know how these are going to be used and who their end users will be. Models are necessary because of the variation of use in practice. That is why there is a need for realistic rules and regulation based on *user models*. By projecting these user models on the model of a building, in terms of floors, working spaces and partitioning elements, we then can list functional and performance requirements.
Functional and performance requirements. Functional requirements describe the requirements of a building in a functional sense. The performance requirements for a building and its parts depend on their function and use.
Modifiability. Naturally, the rules and regulations system reacts to ever changing opinions in the society. In the past decade, for instance terrorism, climate change and sustainability moved to top positions in agenda. Undoubtedly, new requirements and objectives will be added in the coming decades which cannot be foreseen for the moment. We should be able to change the rules and regulations as easily as possible, with minimum economic effects for users and real estate managers, while retaining previously acquired rights.
Knowledge. Many rules are clear-cut. But it is not always clear why certain rules exist or why others *don't*, or why specific terms are used. Often, the persons involved have stored this background knowledge in their minds, but it is not at all or hardly available to third parties. That is why this knowledge has to be publicly recorded and everybody will be able to properly interpret and apply this.

The government wishes to withdraw from markets that might just as well be left to trade and industry, as underlined in the report of the Dekker Committee *'P*rivate whenever possible, public whenever required'.

Differing from most of the other industrial sectors, the knowledge process in the building sector is highly dispersed, as has been shown earlier and depicted in figure 2. Most of the parties only take responsibility for their own part in the process; nobody feels any overall responsibility. The chain of responsibilities is poorly organized in the building sector and the process highly fragmented. This might be different in other countries, but it is the case in the Netherlands. We are highly dependent of the smooth cooperation of all parties. This has its advantages but also many disadvantages.

 ISBN: 978-1-84219-840-7 .

The system of regulations and Standards forms an essential link in the knowledge process, so we should continue to invest in it for future development and maintenance. However, that does not happen sufficiently. In figure 4 we have indicated several points of necessary improvement in the knowledge cycle.

The present public system of assessment against building regulations is aimed at the granting of an "Environmental" permit in case of a construction or renovation project. But the authority will never be responsible and will never guarantee that the building fulfills the regulation. The authority does not have the duty nor the capacity to check the whole building process. Many people have the false hope that the Authorities will guarantee that the performances of the building will be in line with the regulations and the market wishes. Reality is that most of the buildings do not fulfill the regulations, a lot of mistakes are made and that contractors do not feel the responsibility en liability. They say „we have a permit and it is accepted by the Authorities".

The owner of real estate is responsible that the building will be in line with the regulation. The Authorities should issue penalties in case if non compliance. But the Authorities do not have the manpower and the knowledge to do so. In reality we don't know whether buildings comply or not. The owner doesn't know what the performance is of his real estate, nor the requirements. When transferring to a new owner or tenant no one knows what quality is sold or rented.

To break through this false chain we propose the following:

- A technical assessment of the construction project will be no longer be necessary on beforehand, but just before occupation of a building it should be clearly stated and documented by a recognized, independent body, that it meets the regulation; if not the use of the building will be forbidden; in the environmental permit this clause will be standard implemented. How much documentation is necessary depends on the level of regulation that is applicable (simplified solutions, performance based clauses or probabilistic methods).
- The regulation for existing buildings will be based on the Civil Law so that liabilities are clear and people can submit objections and complaints at the Civil Court Chamber; experts of the Knowledge Institution can advise the Court on the technical content.
- When transferring real estate (sale or rental; conveyance) a guaranteed documentation of actual performance will be handed over for which the seller or landlord is liable;
- All parties involved, also the normal man in the street, can complain at a new Body in case of unsafe or unhealthy building in the neighborhood.

By changing the system in this way and by changing the content of the building regulations and the process to develop and maintain the regulations as mentioned before, self regulation of the marked will become possible and a knowledge push will take place. All parties concerned will probably take insurance so they can bear their responsibilities and liability. Not the Law dictates the duty to insure, but the market system will realize that by itself. That also will strengthen the quality chain. This innovated system will give a upward impulse to realize real performances to the level that the market expects. This system will only function when the knowledge chain is closed.

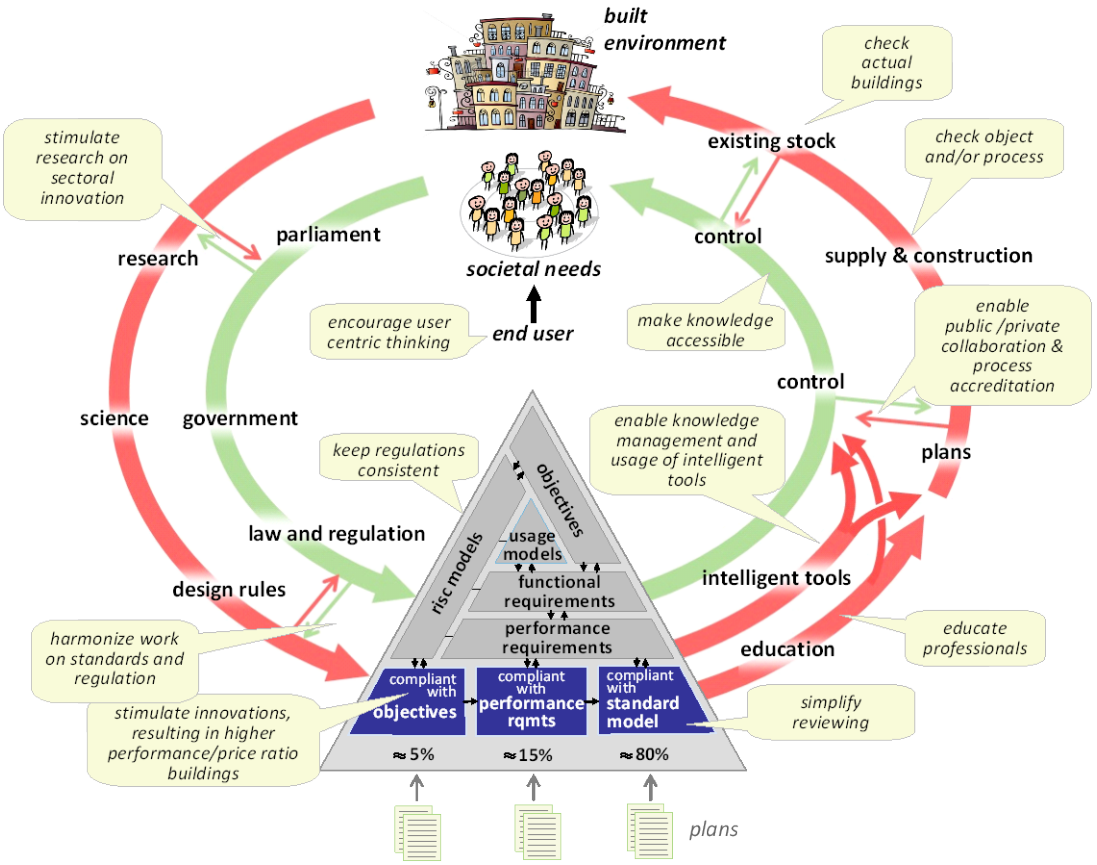

Figure 4: Vision on future development of building regulations in closed and linked public and private law chains of knowledge (Scholten, et al. 2010)

The implementation will create new functions. Acknowledgement should be organized for independent technical-legal arbitration, so that for parties that have a conflict on technical points, the dispute can quickly be settled on technical-legal arguments. The formal road of objection and appeal according to the General Administrative Law is much too cumbersome for this and can be evaded.

Furthermore, knowledge should be easier accessible and actively promoted through training, publication, the internet and knowledge systems. Thus transferred to professionals in the building chain as well as to the law enforcement organizations.

Moreover, emphasis could shift from design to process assessment, and possibly to process certification. That is to cover the complete process from design to the building process, including quality management and guarantee after acceptance/completion. This quality related thinking (ISO 9001) has been accepted in many sectors of industry, but what would this mean for the structurally so fragmented building sector? The ultimate test in quality related thinking is customer satisfaction, but as already stated, the actual customer, the end user, generally, takes no part in the Dutch building process, except the scarce homebuilding principal . Besides, designers, contractors, suppliers, and authorities have shared responsibilities: nobody feels accountable for the whole process. Although integrated contracts are becoming more popular -partly as a consequence of the need of integral accountability -they still only constitute a small part of the present market of construction and refurbishment.

With a coherent approach also methodical improvements can be implemented and monitored leading to a more consistent practice that, by means of reference, can become part of the same chain of knowledge.

ECONOMIC AND SOCIETAL RELEVANCE

Structured regulation has a key role in the translation of essential needs regarding the built environment. As we are all regular users of that built environment, whether it be living, working, recreating or travelling, that regulation is essential for our society.

However, everything has its price. When we look specifically at the development, learning, applying, enforcing and implementation of the rules and regulations – which we have symbolically represented with the two knowledge circles in figures 2 and 4 – then this refers to a process which involves thousands of specialists on a daily basis. There are no exact figures on this commitment of people and costs.

The construction, management and maintenance of real estate involves substantial amounts of money. Some expenses directly contribute to the quality of the built environment; other expenses are needed solely to apply regulations, so at the best they contribute indirectly to the safety, health and sustainability of buildings. The latter expenses ERB estimates for a big part unnecessary.

Moreover, costs arise when a design or existing work does not meet the regulation, because the applicant simply knows them insufficiently and the regulation is not enforced. At present, enforcement takes place mainly by means of random checks based building plans on paper. Enforcement should take place much more on the basis of buildings actually constructed, specifically with a view to the real risks for which this regulation has been written.

In the ERB study report it is demonstrated in a conservative estimation that by implementing the proposals every year more than € 1 billion can be saved on a turnover of € 20 billion. Other benefits will be;

- Better and more understandable building regulations;
- A very simplified process to get the environmental permit;
- Better environmental performance ;
- Less disputes;
- More satisfied people in relation to the quality of buildings.

THE STEPS TO TAKE

The ERB report 'After Dekker' describes actions to be taken to innovate the building regulations and the building assessment system. First of all the parties concerned have to sign a covenant that outlines their intentions, their duties and their rights. The Government has to provide starting capital to finance the creation of the independent Knowledge Institution and the first steps of the renewal of the system of building regulations (stating the objectives). Also the Government has to decide the necessary changes in the laws and the moment that the environmental permit system will no longer need the technical assessment of a building plan, but in stead owner and contractor will have to declare the performance at the occupation moment.

When those decisions will be taken all other improvements will follow as the logical outcome of the new structure. All parties involved can finance yearly the Institution from

their savings every year, estimated at least the € 1 billion predicted efficiency improvement.

At the moment the Parliament is in discussion with the Ministry about the future of the building regulations and the innovation that is needed. The reports of Actal, EIB and ERB are therefore starting point. The need is the higher because of the political discussion about the limited quality of Building Decree 2012.

6. ACTAL AND EIB-STUDIES

The Actal study is complete in line with the ideas of the ERB-study. The differences are that the ERB-study is comprehensive, both in regulation steps as in process steps, with an activity plan, time schedule and cost reduction estimation. The Actal study only does suggestions without further motivations and conclusions.

The predominantly monetary EIB study calculates costs and benefits of rules and regulation. They focus on rules and regulations that they define as unnecessary, because they are not cost effective. The study sees balconies and sheds as unnecessary: houses are cheaper without. The same applies to high standards for energy saving. The calculation of the savings of money is too high: it is not related to the effects in reality (e.g 10% less balconies, because the majority of houses still gets them) but takes the costs of all balconies because they are not longer an obligation. For other aspects they argue that the rules are not effective and thus unnecessary (the measurements of staircases). We think this is an argument for better regulation, not doing without. In total the study counts to 0,5 billion cheaper construction without these rules, which is only theoretical and highly overstated.

A Risk Response Plan Framework for Housing Construction Project Delays in the UAE

Omayma Motaleb[1] and Mohammed Kishk[2]

Scott Sutherland School, Robert Gordon University, Aberdeen, UK

ABSTRACT

The risk response plan in delays control is a crucial process in risk construction project management. However, it has not yet been fully implemented in many construction companies in the United Arab Emirates (UAE). Furthermore, few studies provide evidence of its impact on control delay risks. That said, it is known as a guiding tool in decision-making to reduce conflicts and increase co-operation among the project stakeholders and to create the essential conditions for optimal risk identification and assessment to determine whether a risk has increased or decreased. This has encouraged construction companies to focus more on the development of strategies to avoid such delays through risk mitigation (reduction, avoidance, transfer, or absorption). Demonstrating a close-fit view with past and recent research as published in the literature, this paper discusses preventive and mitigating measures for risk response plan development from several options. A case study in a PPP construction company for housing development in the UAE was investigated. The risk responses used were risk reduction and risk absorption, applied due to the nature of the risk involved. To validate the preliminary results from the case study, structured interviews with engineers, project managers and managers in the contractor and consultant companies dedicated to the project were conducted. An adaptive management framework for developing risk response is then suggested on the basis of the outcomes from the case study and the analysis of the interviews.

Keywords: construction delay, delays risks control, project management, risk response plan, UAE.

INTRODUCTION

Most organizations attempt to manage their risks within the identification and assessment process. Such development has generally been considered to ensuring comprehensive identification and assessments of risks through project planning in the risk management (Cooper and Dale 2005) however, identification and assessment will be worthless in the risk management process unless risk response can be developed and defined.

As already mentioned, delays risks response planning in construction has not yet been fully addressed, but over the years, many studies have been undertaken in quite different environments, and have critically reviewed the issue of delays in order to determine the causal factors. From these studies, it is known that there are significant factors related to

the client and project managers (Ahmed, et al. 2003, Motaleb and Kishk 2011), the contractors (Dimitracopoulos 2008), and financial problems, possibly coinciding with the recessions arising in 2008-2009, such as poor cash flow, funding programme constraints, and payment delays, that are related to the economic situation (Sweis, et al. 2008, World Bank Iraq Trust Fund 2009). This situation is not peculiar to the UAE; indeed the effects of the financial crisis are shared by all countries (Motaleb and Kishk 2010, 2011). Consequently, it can be appreciated that the management of the outcomes from each category-related delay risk may require risk response development rather than the traditional management, and accordingly, there would be a need to make certain priorities in the risk response plan.

The objective of the research that underpins this paper is to outline a framework for appropriate risk response management in construction delays for construction companies in the UAE.

Risk Response Management

Having reviewed the literature relevant to risk management, it appears that risk response management is the most important stage in the process since this determines the ability of managers to enhance opportunities and reduce threats in projects. More specifically, the risk response plan has the potential to create the essential conditions for optimal risk identification and assessment that allow managers to determine whether a risk has changed in nature, increased or decreased.

Earlier research has encouraged the risk response through three channels: response by contracts, by retention, and by insurance (Zhi 1995). Some identified responses such as prevention, mitigation, transfer, retention or combination have been considered, particularly in the early stage of the project lifecycle (Thomson and Perry 1992). Detailed preventive measures and contingency plans should be provided by the project manager (Risk Management Guidelines 2003), and they are most valuable at the early stages (Thompson and Perry 1992). Furthermore, reduction, protection, contingency, acceptance, and transfer types (Risk Management Guidelines 2003) are all known to affect the overall strategy of the project, albeit in limited areas of risk (APM 2006). However, although both preventive and mitigation measures are useful, and indeed commonly used in the development of a risk response plan, the mitigation route is identified as the most expensive (Cooper and Dale 2005). Hence, it is advisable for clients to take responsibility for each agreed risk response (Burtonshow 2009), and deal effectively with risk severity for cost effective, time success, positive procurement, quality, and schedule plan outcomes (Sanghera 2010).

In the UAE, the impact associated with delays risks has been attributed to two factors, these being: 1) Limited research, and 2) Traditional management used by construction companies. However, the global financial crisis of 2008-9 was (and remains) a major delays risk, and little understanding has emerged as yet of the extent of the influence occasioned by the financial crisis, on the delays experienced in projects. At the same time, it can be said that few studies in construction management have concerned themselves with exploring how a more developed approach to project management,

rather than the traditional one, could be more valuable (Wysocki 2009). Certainly, it is reasonable to expect that all stakeholders in construction projects should possess sufficient knowledge to enable their effective participation in decision-making, yet their experience of contributing to risk management efforts is limited because of the emphasis on the traditional approach that excludes them. In particular, the quantified risks like change orders, on-time performance, would benefit from such inputs since the traditional project management approach omits these completely, and hence, does not consider the potential for change nor the way to deal with it. Additionally, the traditional management technique has failed to ensure that the most appropriate tools for evaluating the way to respond to risk are used. The adaptive project management cycle as envisioned by Taylor and colleagues (Taylor, et al. 1997), involves learning from experience to control uncertainties or risks, and assessing the relevant assumptions made in light of that experience (see Figure 1). Adaptive management has shown itself to offer a more successful framework for operation than traditional management, in several disciplines such as environmental management (Murray and Marmorek 2004), and recognises the value of the various stakeholders' knowledge in its decision-making (Lal, et al. 2001). Consequently, there is no reason why action levels should not be defined for risk response in construction to identify links between monitoring and adjustment to the responses. With the use of adaptive project management in construction, improved risk response outcomes can be obtained, and hence, improved productivity will follow.

In addition, the review of preventive and mitigating risk response measures, as discussed in the literature, supports the contention that both types of measure are important when considering project risk response development. On the basis of the outcomes from the survey in the case study in Abu Dhabi, and the interview analysis, a framework is suggested as shown in Figure 1.

Figure 1: Adaptive management cycle for construction project risk response (adapted from Taylor, et al., 1997)

RESEARCH METHODOLOGY

The research method involved a literature review which identified key factors relevant to risk response measures, and interviews with the stakeholders in the case study project.

Sixteen structured interviews were conducted with engineers, project managers and managers in the contractor and consultant companies identified in the case study. The structured interview approach may be used when more quantitative data is needed, in effect allowing for a survey of particular parties' attitudes (Yin 2003). The main advantages offered by interviewing include being able to obtain in-depth information on a wide range of issues, and the ability to develop a relationship with the interviewee that might be of use later to validate the study. The case study employs the SPSS to analyse and to help in the presentation of the data, which in itself contributes to the development of a framework for the case study.

The Case Study Project

As part of the development of the country, the Abu Dhabi Government is implementing various projects/programmes to enhance public living standards in the different regions of Abu Dhabi, the capital of the UAE. Housing development projects undertaken by the governmental general services company (MUSANADA) and Nael and Bin Harmal Hydro Export Est. (a prestigious contracting company with annual turnover more than $5 million and a contract value of $30 million) are the main objective. The work involved is the construction of 60 villas. In addition to the construction of these villas, the infrastructure is also to be provided, so activities such as site grading/leveling, sewage works, storm water works, potable water works, electrical work (including the building of a sub-station, and street lighting), road works (including road signs and road marking etc.) are all included within the scope of the work. Additionally, there is all the planning, procurement management, execution, and stakeholder management to be considered and effectively delivered.

Furthermore, because the client (the government) changed the specification for the rooms after securing more information concerning the size of the families who are expected to occupy these villas, all of the villas have had to be internally modified to enlarge the rooms, and this had to be done when more than 50% of the work on the villas had already been completed. After the client's approval, the relevant documents must be submitted to the appropriate authority for the building permit. The traditional risk management extract as presented in Table 1, indicates the consequences of the delay, the risk measures, and the potential risk response.

Table 1: The Traditional Risk Management Extract for Abu Samra Project

Consequence of the delay	**Risk measure**	**Risk response**
Construction of villas cannot start before obtaining the building permit	Client and Consultant should approach the relevant Authorities in order to expedite building permit sanction	Risk reduction
Construction of three villas can be started after obtaining the revised building permit	Client has to co-ordinate with the end user requirement before proceeding with the building permit	Risk reduction
All the constructed villas have to be modified as per the revised design after obtaining the revised building permit	It is a major risk	Risk absorption

RESULTS AND DISCUSSION

This section reports the results of the structured interviews conducted to understand the measures for risk response development according to the case study project. To improve the risk response, twenty-two preventive measures (in pre-construction) and fifteen mitigating measures (during construction) were identified from the literature with a 1-3 Likert Scale. The preferred measures as indicated by the interviewees are considered to be (1= least recommended, 2 = recommended and, 3 stands for highly recommended):

- In respect of the preventive measures (pre-construction), the top factors as identified by the interviewees (considered to be highly recommended) are: more anticipated risk identification (62.5%), and prepare a programme from previous experience observing the effect of the financial crisis (50%) while the factors considered to be recommended are: contingency plan development (62.5%), improve decision-making support system (62.3%), knowledge in product positioning and market success-technological development for market competition (56.3%), significance shared with stakeholders' effective communication (56.3%), high share impact risks with other stakeholders (risk owner) (56.3%), proper performance knowledge proper quantitative and qualitative risk analysis (56.3%), and prepare advance programme from past learnt projects under financial crisis effects (50%). In addition, developing knowledge base for planners, contract performance (50%), develop labour knowledge (50%), and proper risk management training (50%).
- In respect of the descriptive mitigating measures during construction, as shown in Tables 2 and 3, the interviewees indicated a new core for adaptive management using the reduction risk response type development as follows:

Table 2: Risk Response Development during Construction (highly recommended)

Mitigating measures (reduction)	**Frequency**	**Percent (highly recommended)**
Develop change management (in variations)	9	56.3%
Exchange of adequate incentives and rewards-between contractors and clients	9	56.3%
Use past lesson learnt	8	50%
Up-dating project schedule for any new identifying risk-avoidance	8	50%

Table 3: Risk Response Development during Construction (recommended)

Mitigating measures (reduction)	**Frequency**	**Percent (recommended)**
Manage the overlapping activities considering budget and schedule	11	73.3%
Delay re-analysis	10	62.5%
Proper plan for optimal risk allocation	9	56.3%
Increase project team productivity –resources (Expert manpower/efficient equipments/ technology)-risk buffering	9	56.3%
Improve Municipality inspections process for change requests	8	50%

- 62.5% are preferred to proceed into transfer risk response type, and 62.3% preferred to absorb the risks by new risks reviews and updating the risk plan under any new approval permit.
- 50% have agreed on the effect of the stakeholders on the project objectives (time, cost and quality) and 56.3% have strongly believed the project manager is the most important person in delays risks control. More specifically a trained project manager is preferred by 62.5% of respondents.

The quantitative approach was adopted to allow for an easy comparison to be made between the key issues identified from literature and the different dimensions identified in the data collected from the interviews (i.e. participants' experiences of the case study project, and their reflections on how changes and improvements could be achieved in the future).

Accordingly, the proposed framework for the project risk response plan adopts a cyclical form, representing a different approach from the traditional management strategy, thereby introducing adaptive management (see Figure 1). Such a change in management style will facilitate the achievement of the stipulated project goals (time, cost, quality) and more specifically, a reduction in time:

1- The suggested preventive and mitigating measures should be schematic and placed at the core of the company's new strategy which should take account of stakeholders' opinions and the new and iterative risks, like client change orders, which are frequent in the UAE. Hence, there should be a strong client focus.
2- The client and the project team/stakeholders should develop the preventive and mitigating measures scheme accordingly.
3- The client and the project team together should develop the design and budget for plan B (contingency) by passing through many iterations until they have met the client's defined goal, and only then should they move to the next stage (design risk response plan).
4- The design and budget should be revised at the 50% design stage when there is a possibility to change if necessary. During this stage the client and the stakeholders might encounter the need to make many changes (implement risk response plan).
5- The final development of the design (100%) should be a client-focused step to finalise the project parameters for client sign-off to proceed to the construction documents (monitor the risk response plan).
6- Similarly, the construction documents process (permits, new approval) should follow the same development as in numbers 4 and 5.
7- Finally, adjust the risk response plan accordingly.

As outlined above, there should be two groups of measures developed, the preventive measures in pre-construction and the mitigating measures during construction, and the risk manager should identify alternatives/contingency plans or options as a strategy to minimise delay risks. However, such alternatives should not imply that the business direction of the project changes. Rather, the idea is to be flexible in the

management style, effectively ensuring an adaptive management approach in which all stakeholders are involved.

CONCLUSION AND FURTHER WORK

Both the literature and findings from the case study supported the argument for risk response improvement in the performance of stakeholders and projects. The use of the adaptive framework can be perceived as valuable in bringing success to a project through its use of two measures that could improve the nature of project stakeholders' performance. The first set of measures are those described as preventive and should be introduced in the pre-construction stage as a result of more concentration on risk identification, contingency planning, improving the decision-making support system, knowledge, etc. The second set of measures are those described as mitigating measures, and these involve the development of change management (variations), exchange of adequate incentives and rewards (between contractors and clients), building on the knowledge gained from previous experience, etc.

This study has identified a number of interesting aspects in the risk response management of construction delays in the UAE. The development of a response to risk is essential in order to control delays risks. The research work has shown that both the literature and the findings of the case study call for risk response development in an effort to making improvements to traditional management approaches by the introduction of adaptive management, which would have as its core, preventive and mitigating measures development. A framework has been developed in seven steps considering both stages (design and documents at 50% and 100% stages) to identify and finalise client goals and the method of stakeholder management. Accordingly, risk response would be adjusted.

The limitation of the current study is the single case study approach. There was a need to investigate further how project 'success' is achieved, particularly in relation to developing risk response strategies in construction companies in the UAE for the following areas: (1) Stakeholders and risk management (eg. decision-making support, skills development and training, etc.); (2) The construction process (eg. developing risk response measures in the pre- and during construction stages).

ABSTRACT

The risk of deviations on construction projects has been high. However, without a methodology to identify the sources of project cost and time deviations, construction deviations have been a necessary part of the project. The City of Rochester recently adopted the best value PIPS approach to minimizing project risk. It has minimized the need for client project management and also changed the paradigm of delivering the project. It has identified a major source of project deviation as the client and their design representative. It has also shown the need for the participants to use a different paradigm of being proactive instead of reactive.

Keywords: risk minimization, best value education, mediation, performance information, decision making.

INTRODUCTION

Construction risk can be defined as project cost and time deviations (Kashiwagi, 2012). Delays, cost overruns, and misalignment of expectations can be common in construction, and especially complex projects (Heijmans & Hyland, 2012; Bosch-Rekveldt, M. *et al.*, 2010). Larger more complex projects which have more participants have a greater potential for risk, but all projects seem to have the risk of time and cost deviations (Benta, 2011).

This paper documents the City of Rochester's (Minnesota, United States) approach to implement a proactive risk management system that increases transparency of all parties. The paper begins with a brief literature review to help define "risk", current risk management practices in construction, and a review of best value (BV) procurement processes. The paper also discusses modification of the best value selection criteria, and concludes with a discussion of the system's impact on the delivery of services at the City.

There are two primary objectives of this paper:

- Document a methodology that reduces decision making and need for technical expertise during selection

- Explain the implementation of a best value approach to manage projects and resolve issues

Literature Review

The traditional low-bid procurement system is riffed with problems: it can attract companies "hungry" for work that use change orders during the project to make up the cost (Winston, 1999); there is a lack of expertise in the environment (Angelo, 2003); higher number of claims, schedule delays, and public safety issues (ENR, 2001); and a potential lack of money to successfully complete the project (Anonymous, 1998). The alternative to "low-bid" is "best value", where the owner considers multiple factors during selection: technical capabilities, financial viability, past performance, and of course, price (Gransberg, 1996). One such best value system is the Performance Information Procurement System (PIPS) (Kashiwagi, 2012).

"Risk," in a general business sense, is an event that somehow affects a company's finances, and risk management is the process by which companies eliminate such events, or minimize their impact (Kraman & Hamm, 1999). Risk, as considered in the construction industry, is anything that increases project schedule or cost, or decreases customer satisfaction (Kashiwagi, 2002). Therefore, logic follows that in order for construction personnel to perceive the existence of risk, they must measure their projects (Cotts, 2010). Cotts suggests that the only way for personnel to actually improve their ability to meet customers' objectives is by consistently measuring their performance over time.

Simply identifying the presence of, or potential for, risk does not necessarily mitigate it. Some literature suggests that the accountability and control of actually minimizing the risk should be left to the expert (Kashiwagi, 2012; Sullivan & Guo, 2009). In fact, this literature suggests the following approach to risk management:

1. Before awarding a contract, the owner, or their representative, asks the expert to identify their overall plan to successfully complete the project.
2. Within this plan, the expert should clearly explain anything that could stop the project from being completed in accordance with their baseline expectations (in terms of cost, schedule, or customer satisfaction).
3. Once the contract is signed, the expert should document the sources of any deviation to the baseline expectations.

PROBLEM

The risk of deviation on construction projects is high and the management of the risk has become a necessary part of managing the construction project risk. As a result, miscommunication, lack of accountability, cost and schedule deviation, and owner dissatisfaction become a regular part of an owner's projects. Therefore, the problem is that owners do not have a structured selection system that minimizes biased decision

making, and project management methodology that clearly monitors performance in terms of deviation from the baseline expectation.

HYPOTHESIS

The authors' hypotheses for this paper are as follows:

1. A structured selection approach will help the city obtain the best value for the lowest cost
2. The PIPS best value system clearly documents deviations and assigns accountability to the appropriate party
3. The overall best value system helps participants be more proactive in resolving issues before they become cost or schedule deviations

METHODOLOGY

The authors used the following methodology to test the hypotheses:

1. Pilot the PIPS best value selection process on several construction and professional services projects at the City of Rochester
2. Implement a risk management and documentation system that shows the source of risk
3. Monitor the results in terms of performance over time

IMPACT OF THE BEST VALUE SYSTEM

The City of Rochester has used the PIPS Best Value process since December 2009. In that time, they have used it on four phases of the new Public Works Transit Operations Center (PWTOC), the Rochester National Volleyball Center (RNVC), and the Lenwood Height Neighborhood sanitary sewer and water main upgrade project. Additionally, the City piloted the PIPS selection methodology for the evaluation of the 2nd Street SE Reconstruction's (2SE) Statement of Qualifications. This project was part of the Minnesota Department of Transportation's (MnDOT) design-build pilot program. The City publicly released the budget for each project as part of the Request for Proposals (RFP) documents.

Best Value Consideration of Price and Lowest Bid

Table 1 below shows the project budget, best value awarded contractor's base cost, average proposal base cost, and the lowest proposed cost for each pilot project. Note that the proposals for 2nd Street SE Upgrade and Lenwood Heights projects have not yet been received as of the time of this writing; thus, the cost information for these two projects is not available.

Overall, the best value proposers' cost is 20 percent less than the budget, and 3 percent less than the average proposal cost (we have seen similar outcomes on numerous other best value PIPS projects). These results are important for two reasons. First, the large differential between the best value proposal cost and the budget suggests that giving the budget as part of the proposal does not encourage vendors to arbitrarily increase their costs to be equal to, or slightly less than, the budget. The nature of construction procurements, even in best value environments, ensures that proposals are price competitive. Secondly, the best value proposals are generally more price competitive as compared to the average cost proposal. Owners have occasionally expressed concern that under PIPS, the awarded contractors will have a higher cost; however, the results of these projects should help to alleviate this concern.

Table 2 – Best Value Proposer Cost Comparisons

No	Cost	PWTOC –2	PWTOC – 3	RNVC	PWTOC – 4	PWTOC – 5	Overall
1	Total Budget	28.50	0.40	3.40	1.84	7.80	41.94
2	Best Value Proposal's Base Cost	21.50	0.37	2.75	1.79	6.96	33.37
3	Average Proposal Base Cost	22.10	0.31	2.85	1.89	7.13	34.28
4	Lowest Proposed Base Cost	21.24	0.25	2.75	1.79	4.77	30.80
5	% BV Cost +/- Budget	-25%	-8%	-19%	-3%	-11%	-20%
6	% BV Cost +/- Average Cost	-3%	17%	-4%	-6%	-2%	-3%

Contractors in the Low Price Paradigm

The PIPS evaluation criteria were modified, beginning with the Rochester National Volleyball Center project, in an effort to encourage respondents to identify their technical and risk-minimization capability in terms of metrics. The primary updates to the process were as follows:

1. Separation of the RAVA plan into two distinct, and separately rated, components: Risk Plan and Value Add Plan. Risk Plan should only address events or conditions that could stop the project from being successful. Value Add Plan should increase owner satisfaction, and/or improve performance, and must have a cost impact.
2. Addition of the Project Capability document, which allows the proposers to specifically address their unique abilities to meet the needs and requirements of the owner.
3. Claims must be supported with simple logic and performance metrics in order to receive a "high" rating from the evaluation committee.
4. Change the Pre-Award Kickoff Meeting from an educational session for all participants to one where the potential best value contractor presents their draft Risk Management Plan, Milestone Schedule, and Cost Proposal.

These changes have resulted in 67 percent more claims and risks being supported with documented performance. However, this is likely a result of the proposers providing what was asked for. The percent difference of the standard deviation of the interview ratings between the best value proposer and the other interviewees increased 112%, due to a lower standard deviation of committee interview ratings of the best value proposer. In other words, the best value proposer is becoming more dominant in the interviews, as evidenced a higher level of consensus in the interview ratings. Finally, with the exception of PWTOC – 5, there is an overall increase of the best value firm being ranked first in the evaluation criteria.

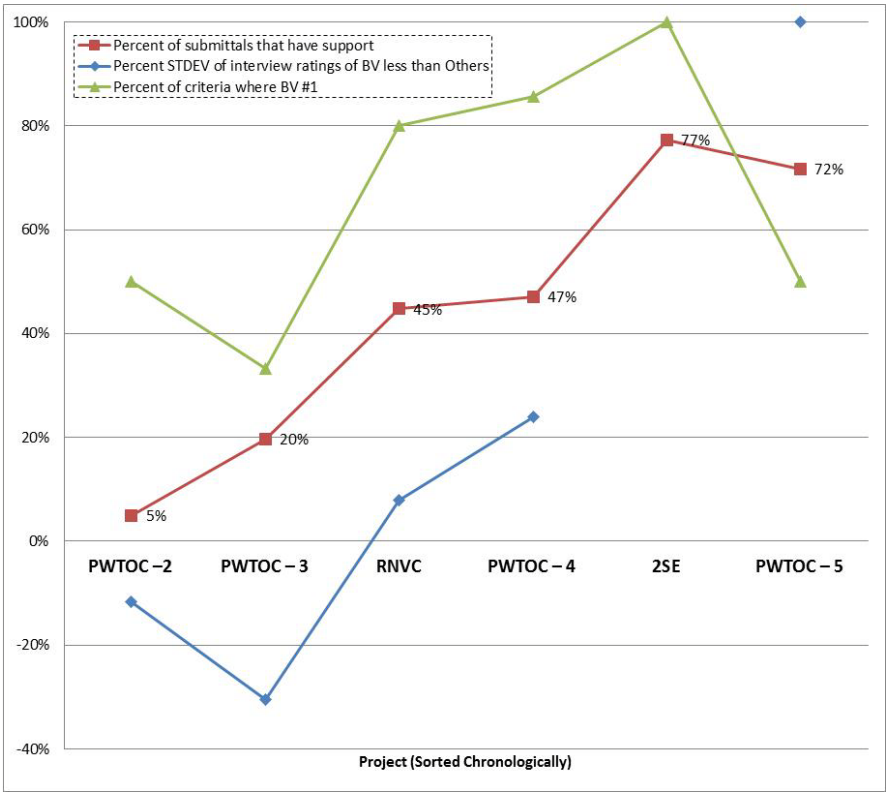

Figure 1. Impact of PIPS Best Value System Changes.

Owner's Gradual Learning of the System

Technical review vs. non-technical review

The aforementioned changes in the system were designed to minimize the impact of evaluator bias and the need for technical expertise in identifying a high performer. The proposers were instructed that their submittals need to address risk they do not control in the following manner: what is the risk, how they will minimize the risk, and how they know their solution is accurate (as evidenced by the inclusion of past performance information to justify their claims). Evaluator decision making (or guessing) on the merits of a proposals is reduced due to the inclusion of performance metrics.

 ISBN: 978-1-84219-840-7.

Methodology in resolving issues

One of the key components of PIPS best value system is the approach in resolving misunderstandings, problems, and unmet expectations. The methodology is as follows:

- Upon identification of an issue, the expert (awarded contractor) should identify a potential solution with cost and schedule impacts, and then notify the owner. The expert should identify a date by which the owner needs to respond.
- The issue should be immediately documented on the Weekly Risk Report, including a description of the risk, a solution, a plan to resolve the issue, who's responsible for the issue, and the cost and schedule impact
- The Risk Management Plan should be updated to reflect any changes in the expert's plan to minimize other risk in the future
- Once the owner confirms acceptance of the plan, the expert will implement the solution. If a response is not received by the due date, the expert to document the delays on the Weekly Risk Report.
- Each week, the owner rates their satisfaction with the expert and their implementation of the plan. This weekly rating is in place simply to increase transparency between the expert and the owner.

Definition of risk and financial responsibility

The final section of this paper reviews five issues that demonstrate the planning component of the best value system.

1. Wind exposure category change ($24,156)

   During the shop drawing review stage, the designer increased the wind exposure rating on a cold storage building to Category C (resistant to stronger winds) from Category B. The subcontractor's updated design required additional material. Thus, the general contractor requested a change order amount of $24,156 to cover the redesign fees and additional structural material.

   Initially, the owner felt that the contractor should have assumed a wind rating of Category C, and included it as part of the initial base proposal. The reasoning was that, while the initial design reflected Category B, the contractor should have known the building would not be acceptable the lower category. The contractor identified that they proceeded with the work without an approved change order to keep the project on schedule. Ultimately, the owner agreed to pay the change order after understanding that while the contractor should have identified upfront the issue, they cannot be financially liable for design errors.

2. Quantity of AIM modules ($20,000)

The project required the installation of Automotive Information Modules (AIMs) in the Fuel Management System. The specifications did not indicate the quantity of AIMs needed, so the subcontractor provided 20 (upon clarification, the designer stated 85 AIMs were required). The owner assumed that the contractors would provide enough to meet the intent of the project (one for "each" vehicle). The contractor proceeded with installation of 65 additional AIMs, with the assumption that the City would approve the additional costs. The City agreed to pay the additional costs.

3. Modification to center parking lot island soil ($9,853)

   The facility has a large center vegetative island in the main parking lot. The drawings provided conflicting information so the contractor assumed the worst case (most expensive) scenario, and made the area into a bioretention basin to match the surrounding islands. Once the site was constructed, the landscape architect identified that is was to be a planting bed, and the City directed the contractor remove the bioretention material, and replace with onsite top soil (at a cost of $9,853). During a mediation session, the architect identified that the contractor should have known top soil was meant to be used "based on the type of grass seeding." The City readily agreed to approve the change order once the entire timeline of events was clearly laid out to all parties.

4. Transverse bars in footing ($12,597)

   While in the process of pouring footings, it was discovered that the structural engineer wanted transverse reinforcement (rebar). The footing schedule did not indicate the need for transverse reinforcement in these footings. The Owner's inspector approved the footing construction up until that time and believed that transverse reinforcement was not required. Upon notification of the requirement, the contractor developed a corrective plan which salvaged some of the footings and adjusted the schedule to accommodate the delivery and placement of the precast panels. The architect identified that a detail indicated the need for transverse reinforcement, although it was a typical (non-dimensioned) detail.

5. Heat pump relocations and modifications ($0)

   The mechanical subcontractor installed numerous heat pumps as identified in the drawings. However, field locations of the pumps were such that they were not accessible for repair and maintenance and the subcontractor had to reinstall per the City's code officials. The contractor requested $16,834 for the additional rework, but the City denied this claim. Field coordination is the responsibility of the experts. If they had identified the risk upfront, the entire issue could have been mitigated before it even occurred.

While the total cost of these particular issues was 0.3 percent ($66,606) of the awarded contract, they have caused a tremendous amount of transaction and stress from all parties.

SUMMARY AND CONCLUSIONS

The City of Rochester has taken a proactive approach to identify construction experts, and has experienced a high level of performance, despite struggles faced in learning a new project management paradigm. In summary, the paper has identified:

- A proactive, risk-minimization approach to construction projects reduces confusion
- An approach use dates, and a simple explanation of events, will minimize transactions, and increase overall satisfaction of all participants
- A major source of deviations is from the owner and their design representative
- There is a need for all construction participants to adopt a proactive paradigm, instead of a reactive paradigm

ABSTRACT

With the advancements and the up rise of the construction market, contractors are forced to deliver larger scale projects in shorter durations. In order to do so, more concurrent activities are scheduled and more crews are needed, which increases the risks of workspace conflicts on sites, eventually affecting the productivity and cost. Thus, there is an increasing attention to identify measures that are able to detect and analyze the possible workspace conflicts that would occur in a project before execution. Currently, practioners perform workspace analysis via expert judgment; however predicting the interference between workspaces is difficult due to the huge number of elements and activities in a project. This paper identifies new measures called "Spatial Temporal Measures" which are measures associated with space and time. It presents the proposed calculation to measure the different workspace conflicts' degree in projects. A sample model was developed to show the calculation of one of the measures: "Worker density per overlapped workspace (WDO)". The paper also presents a case study, where a developed software tool measures the workspace conflicts and minimizes them in the masonry activity from eighty five percent to fifty percent in a residential project.

Keywords: Productivity, Spatial Temporal Measures, Worker Interference, Workspace Analysis

INTRODUCTION

With the growth of the construction industry, projects are getting more complex. Alongside, contractors are being expected to deliver with the highest quality in the shortest period, to be able to survive in this competitive market. This means that contractors need to schedule as much concurrent activities as they can, while maintaining tight control on the workers to insure the quality. One of the problems with contractors

[1] hadyo@aucegypt.edu.
[2] knassar@aucegypt.edu.
[3] ohosny@aucegypt.edu.

executing a huge number of concurrent activities is the appearance of workspace conflicts. Workspace analysis has grabbed the attention of many researchers in the construction industry (Mallasi 2006; Thabet and Beliveau 1994; Sirajuddin 1991). Currently, most practioners analyze workspaces via their technical background and judgment, which requires time and effort and in large scale projects is impossible to process all the data. However, very few researchers have utilized the benefits of the BIM technology and the four dimensional schedules for the analysis of the workspace. Many studies have been introduced where BIM Technology has helped in predicting and forecasting most engineering aspects (Popov, et al. 2010). This study aims to create a framework, identifying new sets of measures called "Spatial Temporal Measures" which are the measures associated with the workspace needed for an element at a certain period of time. The study also investigates the possible actions that could be taken while planning to reduce the workspace conflicts on site. Results of this study would develop a better detailed visualization of the project's execution plan that would help contractors achieve project objectives (finishing the project on time and within budget).

LITERATURE REVIEW

In this section, four main issues will be addressed: What is a workspace? Why do workspace conflicts occur? What is the danger of workspace conflicts on the project cost and duration? How researchers model workspace in a project?

Dealing with the first issue, workspace is basically the surrounding volume around any element that workers would need in order to be able to execute any activities assigned to them. Many researchers (Thabet and Beliveau 1994; Sirajuddin 1991) suggested that any workspace is the arrangement of the crews, their equipment and tools and suitable maneuvering area. Sirajuddin (1991) explained that many planners could conclude the workspace requirements from their previous experience mainly, or could use data as equipment manuals to attain such information. He also added that the workspace arrangement could be concluded from some basic calculations applied to the method statement of the activities. Hence, the main source of information for planners would be their own expert knowledge, and would sometimes utilize the knowledge of other site engineers in complex activities.

However, usually planners don't convey their knowledge properly to the engineers, regarding the workspace arrangements (Cheng and O'Connor 1996). The reason is that most of the current planning techniques involved either hand sketches or 2D diagrams as which are not sufficient to reflect the 3D properties of the workspace (Kamat and Martinez 2001; Morris 1997; Woodward 1975). Many Researchers stated that planners consider the Gantt chart as a favorable technique to reflect project plans, which only reflects what to be done, but not how, hence is not considered as the optimum communication medium (Mallasi 2006; Mawdesley et al 1997). Thus, leaving the workmen on site decide the execution of an activity, which then results in workspace conflicts (Mallasi and Dawood 2001). Consequently, it is safe to conclude that with the increase in number of activities, the project would witness the increase in workspace conflicts.

Moving to the second question raised, whether these workspace interruptions, or sometimes referred to as conflicts, have any effect on the project or not, a question that has been answered by many researchers (Howell and Ballard 1997; Muehlhausen 1991). For example, Riley and Sanvido (1997) while observing four trades for a period of two months in a project reported 71 cases of space-time conflicts. In another case study performed on a 6 million Euro project, evidence indicated that up to 30% of productivity loss was due to the lack of detailed space planning (Mallasi and Dawood 2001). Kaming et al (1998) also presented evidence that the productivity loss due to worker interferences was the highest among eleven other reasons. Their findings were concluded via a structured questionnaire answered by 31 projects managers from 16 different contractors.

Moving to the last part of the literature review, it was found that many researchers focused their attention to develop methods modeling the workspace in projects (Guo 2002; Akinci, et al 1998). Most research modeled three main parts: workspace, equipment space and path space. Researchers would create a database containing a variety of method statements, equipment manuals and codes that would then be able to compute the workspace of an activity automatically. Human input would be required in determining the sequence and the direction of the execution plan. Thus, this data would enable computing the workspace requirements per a given period. Most of the frameworks modeled the workspace as a surrounding space around the element depending on the nature of the activity executed. This paper will focus on the visualization approach called "Approximation Envelope (AE)" that was used by Mallasi (2006) in his research. As shown below in figure 1, the AE forms a virtual 3D box around the element, showing the above, below and surrounding space required. This method has helped research efforts a lot, since practioners could easily explain and detail the workspace of any element using this method. However a question still remains whether the 3D box is the optimum representation for irregular structures, but for certain project types as the residential projects, this concern could be neglected.

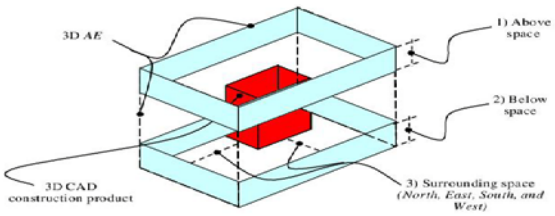

Figure 1 The AE method (Mallasi 2006)

RESEARCH OBJECTIVE

The objective of this research is to identify the spatial temporal measures and develop a calculation method to estimate the degree of each of these measures. Then, to explore what possible actions could be taken to optimize those measures.

METHODOLOGY

The effect of workspace conflict on productivity observed in the literature review varied from one case to the other due to many factors such as: the degree of work space interference, which is a ratio between the workspace affected and total available workspace; the duration of the interference, whether it was for one day or a full week; the nature of the activities being executed; and the nature of the conflict. For example, a workspace conflict occurring due to worker interference differs from a workspace conflict occurring due to an obstruction on site. Similarly, a workspace conflict occurring at a site boundary would have a different effect. Also, it could be deducted that workspace conflicts don't affect the productivity only, but in some cases could affect the quality, and even could violate certain safety measures. However, the goal of this paper is only to identify the different measures and propose ways to minimize them, as it was obvious enough from previous literature that conflicts harm the different projects aspects (Howell and Ballard 1997; Muehlhausen 1991; Riley and Sanvido 1997).

As explained above, workspace is suggested to be the combination of the crews and their equipment and a suitable maneuvering space (Sirajuddin 1991), and by using Mallasi's (2006) AE method, practioners are able to input the workspace required for an element by writing down the protrusion from each face of the element being constructed. This research assumes a uniform rate for execution of an activity, thus assuming a fixed workspace required per day. The other piece of information relevant to be able to model the workspace is the planned direction of execution of the activity. The element is segmented into smaller parts in the direction of construction, maintaining the dimensions in the other direction. For example, if a wall is to be constructed with the dimensions 3 x 0.25 x 3 meters in the X, Y and Z directions respectively in three days, and the X is the direction of construction; then the wall would be segmented into three segments with dimensions of 1 x 0.25 x 3 meters in the X, Y and Z direction respectively, each executed daily. The workspace would be segmented accordingly, based on the dimensions given by practioners. The direction of the construction in addition to the dimensions of the workspace would provide the spatial temporal properties needed for analysis.

After studying the literature well enough, brainstorming with experts in the field were conducted, with the goal of knowing what are the different workspace conflicts and how could they be measures. This paper shows the new measures that are categorized mainly according to the nature of the conflict occurring on site. Here, the types are explained in terms closest to the engineer's daily work to be able to relate to. Listed in Table 1 below are the measures: they have been categorized into three main categories: Crowding measures, Safety measures, and Site boundary measures. There are currently attempts to cover other areas in the project, however the results are still not certain and will not be presented in this paper.

 ISBN: 978-1-84219-840-7 .

Table 1 Suggested Measures and Description

Measure Name	Abbr.	Description
Crowding Measures		
Worker density per activity workspace	WDA	Due to poor resource allocation, the number of crews for the job require a larger workspace than planed
Worker density per overlapped workspace	WDO	Due to the increased number of concurrent activities, crews require the same workspace ate the same instances
Safety Measures		
Safety Zones around equipment	SME	For example, around any crane there are certain areas that work is prohibited in it.
Space Requirement at Building Edges	SRE	The sufficient availability of space for crews to perform the work at higher floor
Site Obstructions		
Work Sequencing Measures	WSM	For example, the early construction of foundations in certain zones could affect the site access
Existing Obstructions	EXO	The effect of any existing obstruction on the progress of the activities

Through the brainstorming sessions, it was suggested that the conflicts should be measured in ratio with the planned workspace per day. Then, a duration factor is added to the model to account for the length of the conflict. Listed below in Table 2 are the equations used to estimate the measures

SAMPLE MEASURE

A sample 4D model was created to show the possible behaviour of the WDO measure in a project. The objective was to construct the walls with the following dimensions as shown below in figure three. The duration of construction was five days for all the activities. All the walls have the same width and height of thirty centimetres and three meters respectively.

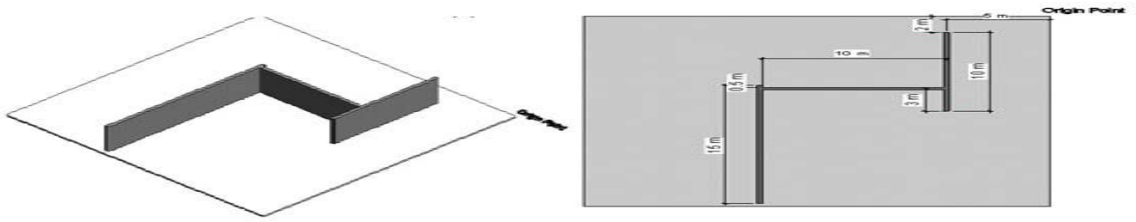

Figure 2 Trial Model and Dimensions

As explained above, data about the workspace dimensions and the direction of construction were inputted to the problem to be able to estimate the measures. The workspace was assumed to be one meter in width and maintaining the same length and height for each wall. Two different scenarios were run and the WDO measure was calculated each time. Figure 4 below shows the data for both scenarios:

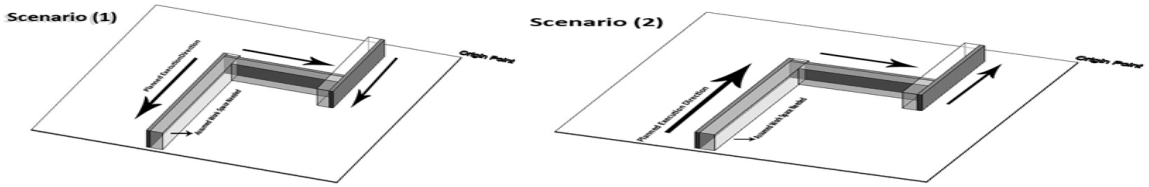

Figure 3 Different Scenarios

Assuming a uniform daily rate, then the progress of the activities for scenario 1 would look as follows:

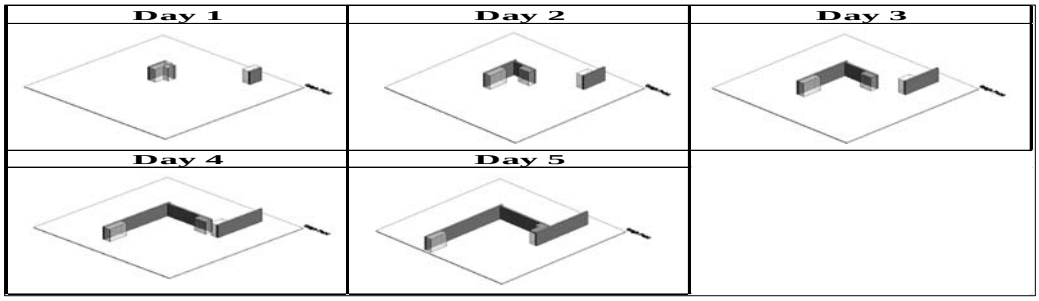

Figure 4 Activities Progress in Scenario 1

Using the equation designated for the WDO measure, it was found that this conflict occurred twice in the first scenario, in day one between Wall 1 and Wall 2, and in day 5 between Wall 2 & Wall 3. The planned workspace volume for Wall 1, Wall 2 and Wall 3 per day was 11.7, 7.8 and 7.8 m^3 respectively. The intersected volume in Day 1 was 7.02 m^3 resulting in the WDO measure of 60% in Wall 1 activities and 90% of Wall 2 activities. Similarly, in Day 5 the WDO measure for Wall 2 and 3 activities was 65%.

OPTIMIZATION OF THE MEASURES

There are many approaches that could change the value of the measures. The first basic approach would be changing the direction of the construction. Another approach could be changing the rate of execution instead from a uniform rate to minimize the works in areas with expected high values of the measures. Also, the workspace dimensions could change according to the modified method statement or resource allocation planned. For example, in the model above when the direction of construction changed as shown for scenario two in figure three, the WDO measure was minimized to zero. The daily progress is shown in figure 5.

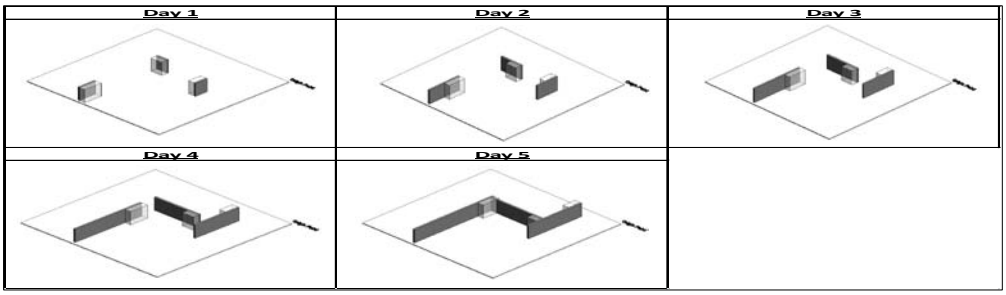

Figure 5 Activities Progress in Scenario 2

TOOL DEVELOPMENT AND CASE STUDY

As easy as the above model could look, in real case projects, the number of elements and activities being executed are multiplied and it becomes impossible to track the measures via simple calculations. Thus, a computer software tool was developed, that would read the geometrical and schedule data from the 4D model, then asks the user for the dimension of the workspace and the direction of the construction of each activity. A case study was applied to a model villa consisting of a basement, ground floor, 2 stories and a roof as shown in figure 6. Currently the software is programmed to decrease the maximum value of the workspace conflicts per activity via genetic algorithms, according to the users comfort. The optimization results of the model successfully decreased the maximum of the masonry activities from 85% to 50%. The optimization was done by only changing the direction of construction. Future work would be extending the software abilities to optimize more than once activity per run, and consider other factors as the workspace size and location and the number of crews are being studied to serve the optimization purposes.

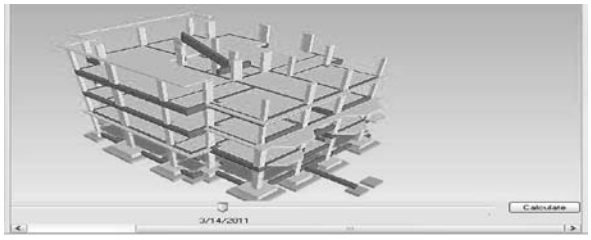

Figure 6 Mock up Villa model

CONCLUSION

This paper suggested a new set of spatial temporal measures with a new calculation approach. The measures don't only cover productivity, but also may help in safety measures, and in the future measures for other aspects as quality could be developed. The software tool developed utilizes the BIM technology and showed promising results regarding the optimization of the workspace results.

ABSTRACT

In the effort to improve construction projects' performance in Nigeria, this study evaluates the influence of design errors on construction projects' performance. The objectives are to determine the stage when errors were detected, compare the level of errors recorded in design documents and determine the influence of the errors on projects outcome. To achieve the objectives, eight project documents prepared during design were selected. A questionnaire survey approach involving a field survey of a sample of 164 projects was adopted. Data were collected using structured questionnaires and analysed using mean, ANOVA and Spearman correlation test. The result reveals that architectural drawings, bill of quantities and project specifications rank highest in design errors. It also reveals that design errors are majorly detected when the activities concerned are to be executed and the errors have significant influence on project outcome. It is concluded that design errors are common features of project documents and that the errors are detected too late and they impact negatively on project performance. Carrying out buildability analysis at design and tendering stages to detect and correct design errors early is suggested as a measure of minimising design errors and improving project performance.

Keywords: Construction projects, design errors, Nigeria, project documents, project performance.

INTRODUCTION

The poor performance of the construction industry in terms of the inability to deliver projects on time, at estimated cost and to required quality standards has remained a major concern to stakeholders in the industry. One of the causes of the problem is inadequate design and documentation of projects. Syam (1995) and Tilley and Barton (1997) maintained that the quality of design and documentation of projects have long been identified as major contributing factors to the inefficiency and poor performance of the construction industry. Tilley (2005) observed that project documents supplied to contractors are substandard or deficient due to incomplete, conflicting and erroneous information. Barret and Barret (2004) discovered that projects that run overtime and overshoot budget are often underpinned by faulty documentation that does not properly specify or describe the built solution while Egan (2002) observed that the perception of what constitutes good project documentation is declining. This study attempts to investigate the influence of design errors on project performance in the Nigerian construction industry. The objectives are to determine the stage when errors were detected, compare the level of errors

recorded in design documents and determine the influence of the errors on projects outcome. The results of the study are expected to reveal the impact of design errors and assist project stakeholders to embark on measures that will minimise design errors.

DESIGN ERROR AND PROJECT PERFORMANCE

Several issues are considered in research studies as design errors. In a study of project stakeholders' perception of design errors in the construction industry, Surther (1998) opined that design incorporates a set of specifications to guide a contractor in developing his means and methods in construction. He described design errors as deviation from drawings or specifications which includes mistake, omission and ambiguity. Davies and Ledbetter (1987) identified three basic types of errors namely: imperfections, non-conformance and omissions. The duo described imperfection as a deviation which does not affect the use or performance of a product, process or service. They consider non-conformance errors as those that do not meet specifications and thus require corrective action and omission as any part of a system that has been left out resulting in a departure from established requirements. In a report of the responses of clients, consultants and contractors to the definition of design errors, Surther (1998) identified errors or omissions and ambiguities in project documents, conflicting design information, incorrect information, misinterpretations of the owner's requirements, inconsistencies in plans and specifications that are foreseeable and require corrections as some of the issues regarded as design errors. The report shows that the issues that constitute design errors are inexhaustible however, the two major features of such issues are that designers should be able to foresee them and they should require correction when detected. In other words, issues that requires designers to provide new or additional information or design to what exists in project documents constitute a design errors.

Several studies have been conducted on the problem of design errors and their influence on project performance. Davies and Ledbetter (1987) maintained that major design quality problems occur during construction when errors, omissions and ambiguities in project documents become evident. The point in this assertion is that the effect of design errors manifest in several ways during construction when design documents are being implemented. This is perhaps the reason why Davies and Ledbetter (1987) asserted that the accuracy of design documents was the most critical of the criteria used in initial evaluation of design effectiveness. Chalabi *et al.* (1987) claimed that the quality of planning and design is one of the primary factors of success in any project endeavour. Kirby *et al.,* (1988), Lutz *et al.,* (1990) and Burati *et al.,* (1992) agreed with the assertion by maintaining that the quality of design and documentation produced has a major influence on the overall performance and efficiency of construction projects. The various ways by which design errors affect the performance of projects have also been the focus of many studies. Tilley and Barton (1997), Love and Li (2000), Tilley and McFallan (2000), Tilley *et al.,* (2002), Andi and Minato (2003) and Love and Edwards (2004) in separate studies discovered that inadequate and deficient design and documentation impact directly on the efficiency of the construction process by leading to delays, rework and variations which in turn contribute to increases in project time and cost. Tilley (2005) observed that poor design and documentation quality standards have often been identified as major contributors to projects running over budget, overtime, rework, variations and disputation. Hibberd (1980) discovered that 60% of variations were directly design and documentation related. Love *et al.,* (1997) found that a large proportion of rework and non-conformance costs are due to deficiencies in design and documentation and in the transfer of information during the design process.

There seems to be an agreement in the findings of the studies reviewed above that design errors are directly responsible for rework and variations which in turn contribute to the final delivery time and cost of projects. In other words, the effect of design errors manifests in the form of time and cost overruns in projects. These two parameters namely: time-overrun and cost-overrun can be regarded as the most prominent parameters of project performance. Hatush and Skitmore (1997) maintained that success in a project is generally operationalized into time, cost and quality. Michell *et al.* (2007) opined that the primary concern of construction clients is that their projects are completed within budget, on time and at the required level of quality. They further stated that timely completion of construction projects is frequently seen as a major criterion of project success by clients, contractors and consultants alike while cost-overruns are identified by them as one of the principal factors that lead to the high cost of construction. Quality which is also a prominent parameter of project performance is not a common project performance parameter in research studies because as Vincent and Joel (1995) put it: stakeholders see the goal of quality management as customer satisfaction.

RESEARCH METHODS

The study adopted a survey design approach that involved a survey of 164 building projects to achieve its objectives. To obtain the study sample, a preliminary survey of recently completed building projects in Nigeria was conducted in 2009 because reliable data of such projects was not available. From the survey, a list of 216 projects was prepared and adopted as the study population. From the population, 164 building projects were selected by random sampling as the study sample while the project leaders who were project managers, architects and civil engineers served as respondents.

The variables used for the study are classified into two, namely: project documents and performance. Eight documents were selected for the purpose of evaluating design errors. The documents are architectural, structural, electrical and mechanical drawings, bill of quantities, project specifications, Occupational Health and Safety (OHS) and quality management plans. Two parameters of project performance namely: time and cost overruns which are regarded in research studies as the most prominent parameters of project performance were used in the study. Data were collected on the characteristics, the initial and final contract periods and sums of the projects and the number of errors recorded in the eight project documents selected. Seven project characteristics stated in Table 1 were investigated. Respondents were requested to indicate the sub-variable of each characteristic applicable to their projects. The data were collected in the five geo-political zones in Nigeria in late 2009. The data were collected with the aid of structured questionnaires which were administered through personal visits to the respondents.

Two hypotheses were postulated in the attempt to compare design errors in project documents and their relationship with project performance. The first hypothesis states that the levels of design errors in selected project documents are not significantly different. The test of this hypothesis will reveal whether or not the problem of errors in project documents differ from one project document to another. The second hypothesis states that the levels of design errors in project documents have no significant relationship with project performance. The results of the test of this hypothesis will reveal whether or not design errors contribute to the performance of projects. The characteristics of the respondents and the level of errors in the selected project documents were analysed using percentage and mean while the research hypotheses were tested using analysis of variance and Spearman correlation test.

RESULTS

The results of the analysis of data collected are presented as follows:

Characteristics of Projects Sampled

The characteristics of the building projects sampled were analysed and presented in Table 1.

Table 1 Descriptive characteristics of building projects used for the study

Characteristic	N	%	Characteristic	N	%	Characteristic	N	%
Client type			**Procurement type**			**Project cost**		
Private	136	82.9	Direct labour	64	39.0	₦ 1-25 million	32	27.6
Public	28	17.1	Traditional contract	42	25.6	₦ 26-50 million	22	19.0
Total	164	100	Design-build	42	25.6	₦ 51-75 million	25	22.4
Contractor type			Labour-only	16	9.8	₦ 76-100 million	8	6.9
Indigenous	122	74.4	Total	164	100	Above ₦ 100 million	28	24.1
Expatriate	42	25.6	**Building rise**			Total	116	100
Total	164	100	Low (1-3 floors)	96	77.4	**Project duration**		
Construction type			Medium(4-7 floors)	6	4.8	Short (1-26 weeks)	48	29.6
New	122	74.4	High (>7 floors)	22	17.8	Moderate (27-52 weeks)	40	24.7
Renovation	42	25.6	Total	124	100	Long (above 52 weeks)	74	45.7
Total	164	100				Total	162	100

N=Number of respondents, ₦=Naira (Nigerian official currency)

Table 1 shows that the study covers projects owned by both public and private clients however, the majority of the projects belong to the organised private sector. The results also show that projects executed by indigenous and expatriate contractors in Nigeria were sampled however; the majority of the projects were executed by indigenous contractors. On the procurement methods adopted, Table 1 shows that projects procured by direct labour, traditional contract, design-build and labour-only procurement options were covered in the study. The results also show that low-rise, medium-rise and high-rise buildings were sampled however; the majority of the projects are low-rise buildings.

On the type of construction, Table 1 shows both new construction and maintenance/renovation works were sampled but the majority of the projects are new construction. The analysis of the duration of the projects reveals that the study sample consists of projects of short, medium and long duration. The analysis of the value of the projects shows that the study sample covered projects of both low and high values.

Level of Errors in Project Documents

To investigate the level of errors in project documents, data were collected on the errors detected in eight documents. The mean errors were analysed and are presented in Table 1.

Table 1 Ranks and test of difference in errors detected in selected project documents

Project document	N	Sum	$\overline{X}$	Rank	f-value	df	p-value	Decision
Architectural drawings	164	186	1.13	1	3.747	7	0.001	Reject
Bill of quantities	164	168	1.02	2				
Project specifications	164	144	0.88	3				
Electrical drawings	164	126	0.77	4				
Mechanical drawings	162	124	0.77	4				
Structural drawings	164	112	0.68	6				
OHS plan	164	92	0.56	7				

Quality management plan	164	74	0.45	8

N=Number of respondents, $\overline{X}$ =Mean, df=Degree

Table 1 shows that the mean of the errors detected in architectural drawings ranks first while those of bill of quantities and project specifications rank second and third respectively. The mean errors in electrical drawings and mechanical drawings rank fourth. The mean errors in structural drawings and occupational health and safety plan rank sixth and seventh respectively while that of quality management plan ranks eight. The results indicate that the errors detected in architectural drawings are the highest followed by the errors in bill of quantities. Errors in project specifications are third highest while those of quality management plan are the least.

Difference in the Level of Errors in Project Documents

The study attempted to determine whether the variation in the errors detected in the project documents investigated in Table 1 is significant or not by postulating the first research hypothesis. The hypothesis states that the errors in project documents are not significantly different. The hypothesis was tested using Analysis of Variance (ANOVA) with $p \leq 0.05$. The rule for the rejection of the hypothesis is that when the p-value>0.05, the test fails to reject the hypothesis but when the p-value$\leq$0.05, the test rejects the hypothesis. The results are presented in Table 1

The results in Table 1 show that the p-value for the test of difference between the errors in the selected documents (0.001) is less than the critical p-value (0.05) therefore the test rejects hypothesis. This result indicates that the differences in the errors detected in the documents are significant. The result implies that errors differ significantly from one document to another.

Influence of Errors in Project Documents on Project Performance

To investigate the relationship between design errors and project outcome, the second hypothesis of the study was postulated. The hypothesis states that errors in project documents have no significant relationship with project performance. The hypothesis was tested using the Spearman correlation test with $p \leq 0.05$. The rule for the rejection of the hypothesis is that when the p -value>0.05, the test fails to reject the hypothesis but when the p-value$\leq$0.05, the hypothesis is rejected. The results of the test are presented in Table 2

Table 2 Results of test of relationship between errors in documents and time and cost overruns

Project document	Time-overrun				Cost-overrun			
	N	R	p	Decision	N	R	p	Decision
Architectural drawings	80	-0.601	0.001	Reject	54	-0.467	0.001	Reject
Structural drawings	80	-0.472	0.001	Reject	54	-0.306	0.024	Reject
Electrical drawings	80	-0.472	0.001	Reject	54	-0.326	0.016	Reject
Mechanical drawings	78	-0.480	0.001	Reject	52	-0.460	0.010	Reject
Bill of quantities	80	-0.347	0.002	Reject	54	0.270	0.029	Reject
Project specifications	80	-0.553	0.001	Reject	54	-0.325	0.004	Reject
OHS plan	80	-0.251	0.024	Reject	54	-0.502	0.001	Reject
Quality management plan	80	0.075	0.508	Accept	54	-0.044	0.750	Accept

N=Number of respondents, R=Spearman correlation value, p=significant value

Table 2 shows that the p-values for the test of relationship between the time-overrun and errors in architectural, structural, electrical and mechanical drawings, bill of quantities, project specifications and OHS plan are less than the critical p-value (0.05) therefore, the test rejects the hypothesis. The results imply that the errors in the documents are significantly related to the overrun in the delivery time of projects. In other words, the errors in the documents have influence on the time-overrun recorded in the projects. Similarly, Table 2 shows that the p-values for the test of relationship between cost-overrun and errors in architectural, structural, electrical and mechanical drawings, bill of quantities, project specifications and OHS plan are less than the critical p-value (0.05) therefore, the test rejects the hypothesis. The result equally implies that the errors in the documents are significantly related with overrun in the cost of the projects. In other words, errors in the documents have influence on the cost-overrun recorded in the projects. However, the p-values for the test of relationship between time-overrun and errors in quality management plan and cost-overrun and errors in quality management plan are higher than the critical p-value (0.05) therefore, the test fails to reject the hypothesis. The result indicates that the errors in quality management plan have no relationship with the overruns in the delivery time and cost of the projects.

Evaluation of the Stage of detecting design errors

Having established that design errors have significant influence on project performance, the study investigated the stage when errors were detected. The stage is important in the efforts to control their effect on project outcome. For this purpose, three design error detecting stages namely: tendering, pre-activity execution and activity execution were identified. Data were collected on the number of design errors detected in each stage. The mean and percentage error in each stage were analysed. The results are presented in Table 3.

Table 3 Descriptive results of errors detected at selected stages of detecting design errors

Stage	N	Sum	%	$\overline{X}$	Min	Max	Stage	N	Sum	%	$\overline{X}$	Min	Max
Arch dwgs							**BOQ**						
Tendering	4	4	2.8	1	1	1	Tendering	1	1	1.1	1.0	1	1

N=Number of respondents, $\overline{X}$ =Mean, Min=Minimum, Max=Maximum

Table 3 reveals that the majority of the errors were detected at the stage when activities concerned were about being executed. Furthermore, the minimum and maximum errors detected

per project are highest at that stage. These results indicate that errors are majorly detected at the construction stage and specifically when activities concerned are about being executed.

Discussion of Findings

The results of the study have shown that the documents rank differently in number of errors detected. The test of the first hypothesis indicates significant difference in the numbers of errors in the documents. The result indicates that errors are common features of project documents however; their extent varies from one document to another. The implication of this result is that efforts to minimise design errors are important and these efforts should be applicable to all project documents. However, the efforts should be applied more to some documents than others. Architectural, bill of quantities and project specifications with the highest number of errors require more efforts than OHS and quality management plan with the least number of errors

The results of the study reveal that the errors in all the documents except quality management plan have significant influence on the outcome of the projects sampled. The implication is that errors are capable of increasing the delivery time and cost of projects. the result agrees with the findings in the studies conducted by Tilley and Barton (1997), Love and Li (2000), Tilley and McFallan (2000), Tilley *et al.,* (2002), Andi and Minato (2003) and Love and Edwards (2004). The study has further established that the errors are often not detected at the tendering and pre-activity stages but remain until the activities concerned are being executed. The result has several implications. First, it shows that the bids submitted for the projects and indeed the contract sums and periods were inaccurate because they were prepared with the errors. Second, when errors are detected at the stage when the activities concerned are to be executed, queries are issued and works in most instances have to be suspended until the queries are answered. The process often involves change orders, rework and delay and all these often lead to claims from contractors which will make a project to overrun its budget and schedule. The point in the results of the study is that design documents are prone to errors and it is often too late before the errors are detected therefore they contribute significantly to the overrun in the delivery time and cost of projects.

CONCLUSION

The study has established that design errors are common features of project documents and the errors contribute significantly to project time and cost overruns. The conclusion of the study is that design errors impact negatively on project performance. The study also established that majority of design errors are detected at the stage when activities involving the errors are about to be carried out. It is therefore concluded that the stage when design errors are detected is too late to prevent the errors from impacting on project performance. The conclusion suggests that at the stage when project participants detect errors in the Nigerian construction industry, the correction of the errors is prone to suspension of work, change orders, rework and delay which contribute to both time and cost overruns. The import of this finding is that project participants need to put in place mechanisms for detection of design errors before commencing construction. It is therefore suggested that project stakeholders especially clients should engage consultants to carry out buildability analysis at the design and tendering stages to detect and correct design errors early enough to prevent inaccurate bids, change orders, rework and delays that can contribute to poor project performance.

ABSTRACT

A high performance manufacturer of waterproofing systems is motivated to: 1) minimize its risk of contractor non-performance, 2) minimize the risk of litigation by users, and 3) attract high performance contractors and end users that will install their high performance product with minimal risk of non-performance. To achieve these objectives the manufacturer must act proactively, minimize risk before it happens, and ensure that their product and installers perform. The manufacturer directed the research group to minimize their risk by 1) organizing a database of vendor performance and user satisfaction, 2) creating a requirement for past performance, tracking all warranties issued, and 3) implementing an Alpha program which used performance information to motivate a group of roofing contractors to perform and be accountable on their warranted work. Concepts utilized by the manufacturer include the concepts of any litigation is bad litigation, the use of a warranty to ensure performance decreases risk, transparency is the best way to mitigate risk, and risk can be proactively mitigated by recognizing potential risk before it happens.

Keywords: applicator, manufacturer, performance information, risk minimization, satisfaction rating

INTRODUCTION

The delivery of construction services has become a topic a source of much dismay for researchers. The last two decades of documented research has revealed a poor performance line documentation of the construction industry (Cahill and Puybaraud, 1994; CFMA, 2006; Flores and Chase, 2005; Egan, 1998; Davis et. al., 2009). Every entity in the industry claims that their service / product is high performing giving false promises to the owner. Expecting a high performing job the owner buys a service / product, but due to poor documentation of performance, manufacturers and contractors sell products based on low price and long term warranties. The false expectation of high performing job, the enticing low price and long term warranties incite clients to purchase products based on these contracts, which has no proven correlation to a systems performance (Kashiwagi 2011). At the end, the contractor

[1] dgajjar@exchange.asu.edu
[2] Dean.Kashiwagi@asu.edu
[3] Jacob.Kashiwagi@asu.edu

takes no accountability for their work and the owner is dissatisfied with the service and the end product creating a "lose-lose" scenario.

This trend is also seen prevalent in the roofing sector of the construction industry. The industry is flooded with manufacturers/roofing contractors who sell roof coating systems based solely on the length of the warranties. Many researchers have suggested different type of risk minimization systems in attempt to change this trend. (Hillson, 1997; CII, 1995; Gibson et. al., 2006; Hamilton, 1996; Kashiwagi, 2009; Sullivan, 2010; Davis, et. al., 2009; Sweet, 2011).

Manufacturer's problem

This paper focuses on a large manufacturer in the roofing industry that was suffering to survive in the market due to these trends. A subject manufacturer was feeling the effects of the ill-performing construction market. This traditional market based on unproven warranty durations, low prices and poor performance made it difficult for this manufacturer to compete. The manufacturer was on the fringe of exiting the marketplace due to the high risk, high costs and low profit margin. The manufacturer claimed that their product was high performing and had no proven documentation that can support this claim.

A specific roofing sector known as Sprayed Polyurethane Foam (SPF) roofing sector is suffering to survive in the price-based market due to poor installation by the contractors. The manufacturer manufactures the coating system for this roofing sector. The manufacturer needed a process to differentiate high performing applicators from low performing applicators in this roofing sector.

Hypothesis

A risk minimization program that measures the performance of the products and applicators can minimize the risk of contractor non-performance and litigation by end users through the identification of low performing applicators and high performing end users that can differentiate the subject manufacturer from other manufacturers.

PBSRG solution

The manufacturer approached Performance Based Studies Research Group (PBSRG) at Arizona State University (ASU) for assistance. PBSRG is a group of researchers at Arizona State University organized in 1994 to develop performance based and best value procurement systems including Performance Information Procurement System (PIPS) and Performance Information Risk Management System (PIRMS). PBSRG also developed the "best value approach" that optimized value, minimized risk and optimized profit through efficient supply chain practices. The approach has been tested over 1000 projects in different services totalling up to $4.7 billion with a user satisfaction rating of 9.5 / 10 (pbsrg.com, 1994)

The most important step a potential owner can make to minimize their risk is to identify if the manufacturers and contractors have documented proven performance that will increase the probability that the roof system will last (Kashiwagi, 2011). PBSRG and the manufacturer identified the following as integral elements to an implemented risk minimization system for the subject manufacturer:

1. Identify if the manufacturers claim of high performing is true

2. Implementing an Alpha Program for sprayed polyurethane foam (SPF) roof system that uses performance information to motivate a group of elite contractors to increase their performance and be accountable for their warranted work.
3. Differentiate their products from other manufacturers by creating a structure to identify high performing applicators and end users using a warranty program.
4. Eliminate contractors that are non-performing and litigation by end users

Identification of Performance

Initially the performance of the product had to be identified. FM-SH Test # 4470 was conducted to verify that manufacturer's coating was a high performance product and can be differentiated from other manufacturer's product based on performance. The results revealed that manufacturer's coating is the only coating system that could withstand the FM-SH Test # 4470 and it was a high performing coating product (Kashiwagi 1996).

Alpha Program

A performance based roofing program known as Alpha program is developed for the manufacturer to motivate contractor performance and accountability. The program is the first contracting performance program that is established by the manufacturer that qualifies and disqualifies applicators on performance measurements determined by the end users. This program was specifically created for a specific type of industrial coatings system known as Spray Polyurethane Foam (SPF). The poor instalment and application of the SPF led the manufacturer to creating a program that would identify professional SPF applicators. The Alpha program minimizes the risk of the applicator, manufacturer and the end user creating a "win-win-win" situation. The Alpha program succinctly curtails litigation that is caused by improper application, motivates contractors to take accountability for their work and increases and creates a competitive market for ensured quality performance (Kashiwagi, et al. 2010).

Alpha program requirements:

1. Have a "good financial standing" and "be licensed" with the manufacturer
2. Roof inspections once every two years of a minimum of 25 roofs by a third-party inspector
3. Annual submission of newly installed SPF roofs over 5,000 SF to Arizona State University
4. 98% of roofs being tracked cannot currently leak.
5. 98% of surveyed roofs must have satisfied customers.
6. The contractors must attend the annual educational presentation given by Arizona State University on the risk management systems.

Applicators can be eliminated from the program if they do not meet the requirements of the Alpha program. Table 5 shows the performance ratings of the applicators currently involved in the program. The data reveals that all of the applicators are high performing applicators with 100% satisfied customers and 100% of jobs that are not currently leaking.

Table 6: Overall performance line

Risk Minimization Warranty Program

Based on the Alpha program, the manufacturer implemented a risk minimization program that measures the performance of all of their systems - Wall Coating, Flooring, Waterproofing, Direct Bond Roofing, and Spray Polyurethane Foam (SPF) Roofing and the performance of the applicators that install the products. In order to measure the performance of the system, clients/end users are contacted every year until the end of the warranty duration for satisfaction ratings on the product and the applicator who installed the roof system.

The risk minimization warranty program attempts to minimize risk by updating the information on:

1. Not using applicators that have no experience or do not show past performance information on successful projects
2. Concentrating on the larger investment and / or size of project
3. Identifying dissatisfied end users, and mitigating the risk immediately through annual follow-ups

The risk minimization program consists of a warranty check process outlined in Figure 1. Upon finishing a project, the manufacturer will start the warranty check process by sending the warranty to PBSRG and the applicator. As soon as the warranty is issued to the end user, PBSRG will survey the end user with the following questions:

1. Customer Satisfaction of the Applicator (1 lowest– 10 highest)
2. Would you hire the applicator again? (Yes / No)
3. Customer Satisfaction of the coating system (1 – 10)
4. Would you purchase the system again? (Yes / No)
5. Overall Customer Satisfaction (1 – 10)

The survey response information (performance information) is then reported back to the manufacturer. If a satisfaction or an installation issue is identified in the survey, the manufacturer's customer service department will receive the project information. This proactive risk minimization system enables the manufacturer to identify and resolve problems upfront, rather than becoming reactive to them as they materialize in the future.

 ISBN: 978-1-84219-840-7 .

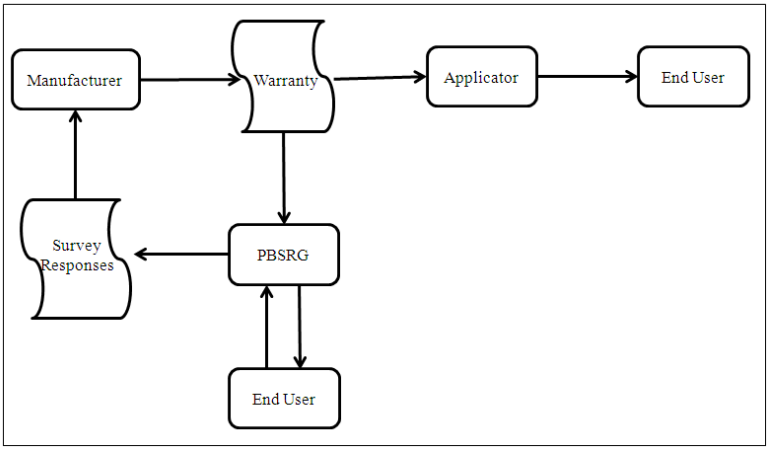

Figure 1: Warranty Check Process

Table 1 shows the performance information of all manufacturers systems over the last two years. The total job area surveyed was 18.3 million square feet. The clients were satisfied with manufacturer's product and the applicators who installed the product. The overall customer satisfaction rating was 9.1 with 674 warranted jobs surveyed. Flooring has a satisfaction rating lower than a nine because of fewer warranties issued by manufacturer for flooring. Nine out of ten flooring clients were satisfied and would use the same product and hire the same applicator again. Overall percentage of clients that would hire the same applicator again and use manufacturer's product again was 97%.

No	Criteria	Unit	Overall	Flooring	Direct Bond Roofing	Foam Roofing	Wall Coatings	Water-proofing
1	Overall customer satisfaction	(1-10)	9.1	8.3	9.2	9.1	9.3	9.0
2	Oldest job surveyed	Years	5	2	2	2	4	5
3	Average age of jobs surveyed	Years	2	2	2	2	2	2
4	Customer Satisfaction - Coating System	(1-10)	9.1	8.1	9.3	9.3	9.2	9.0
5	Percent of customers that would purchase the product again	%	97%	90%	98%	100%	98%	98%
6	Customer Satisfaction - Applicators	(1-10)	9.0	8.3	9.2	9.0	9.3	9.1
7	Purchase of customers that would hire same Applicator again	%	97%	90%	98%	97%	98%	97%
8	Total job area (of job surveyed)	SF	18.3 M	0.05 M	1.8 M	1.2 M	2.6 M	12.7 M
9	Total number of jobs surveyed	#	674	10	97	32	59	476
10	Total number of different customers surveyed	#	292	3	48	19	21	201

Table 1: System Performance Information

Table 2 shows the performance information for jobs that hold potential risk. Jobs that have satisfaction rating below seven or clients that would not purchase the product again were categorized as risky. The data shows that 97% of jobs have no customer complaints and would purchase the product again. However, the risky jobs have a lower satisfaction rating of 4.1 for the coating system and 4.5 for the applicator. The risky jobs constituted only 3% of the total job area installed. PBSRG sends a quarterly report with a list of all identified “risky” jobs to the manufacturer customer service department. The customer service then contacts the client for further investigation and the actions that need to be taken to satisfy the customer.

Criteria	Unit	Risky Jobs
Total number of jobs surveyed	#	674
Number of risky jobs	#	20
Percent of jobs that are risky	%	3%
Satisfaction rating- Coating	(1-10)	4.1
Satisfaction rating- Applicator	(1-10)	4.5
Percent of customers that would purchase the product again?	%	0%
Risky job area	SF	0.6 M

Table 2: Risky Job Performance Information

Table 3 differentiates high performing applicators from low performing applicators. Applicators that have either a satisfaction rating below seven or a client that would not hire the applicator again, are deemed as low performing contractors. The data

shows that approximately 10% of the applicators that install the manufacturer's product are low performing applicators. Low performing applicators installed 5% of the total job area of manufacturer coating.

Criteria	Unit	High Performing Applicators	Low Performing Applicators
No. of Contractors	#	268	29
Satisfaction rating- Coating	(1-10)	9.2	7.4
Satisfaction rating- Applicator	(1-10)	9.3	6.1
Percent of customers that would hire the applicator again	%	100%	69%
Total Job Area	SF	17.2 M	1 M

Table 3: High performing applicators vs. Low performing applicators

License System (Filtering out low performing applicators)

The installed risk minimization system showed that 10% of the manufacturer's applicators were low performing. In 2010, researchers proposed a license system that would severely minimize their risk by disqualifying low performing applicators to receive joint warranty options. Joint warranty contracts state that the responsibility to uphold specifications of the warranty is equally shared by the applicator and the manufacturer. By creating a system that the filters out low performing contractors, it mitigates its risk of failing warranties and litigation.

Licensing requirements:

1. Submit a minimum of five references that validates their credibility as a high performer. (One of the jobs must include the use of the manufacturer's product)
2. Survey responses from the references answering the following questions:
    a. Customer Satisfaction of the Applicator (1 lowest– 10 highest)
    b. Would you hire the applicator again? (Yes / No)
    c. Customer Satisfaction of the coating system (1 – 10)
    d. Would you purchase the system again? (Yes / No)
    e. Overall Customer Satisfaction (1 – 10)

Table 4 shows that seventy two percent of the applicators that applied did not get licensed after the introduction of the license system. Many of the applicators were disqualified due to non experience of using the manufacturer's product.

Criteria	Data
Total number of applicators applied for licensure	271
Number of applicators licensed	77
Percent of applicators that did not get licensed	72%
Average satisfaction rating of licensed applicators	9.5

Table 4: Applicator licensure analysis

CONCLUSIONS

Manufacturer has successfully identified itself as a manufacturer of a high performance coating system.

The high performance roofing program known as the Alpha program increased the accountability of the applicator through the use of documented performance information and likewise minimizing the manufacturer and the client's risk. The research showed that 100% of the roofs installed by the Alpha applicators are leak-free and 99% of the end users were satisfied with the job. The Alpha program helps the manufacturer minimize litigation and risk through the use of performance checkups, licensing practices and inspection programs. This program not only provides an on-going development feedback system to better serve clients, but helps contractors to compete in a high performance based environment.

Manufacturer has implemented a performance based risk minimization program that not only measures the performance of their coating system, but also the applicators installing the coating system through the tracking of warranties. Risk minimization program helps manufacturer differentiate themselves from other manufacturers that sell products based on warranty and low price by organizing a database of vendor performance and end user satisfaction.

The license system filtered out low performing applicators from installing the manufacturer's product. The references check requirement minimized the risk of the manufacturer by filtering out low performing applicators from using their product.

ABSTRACT

A roofing manufacturer is motivated to increase the accountability, minimize the risk and differentiate themselves from other manufacturers to increase their sales. In order to achieve this, the manufacturer directed the research group to minimize their risk by implementing a warranty program that measures the performance information of their systems and applicators by end users. The manufacturer submits a list of warranted jobs to the researchers, researchers perform a satisfaction check by calling the end users and reports back to the manufacturer. Concepts utilized by the manufacturer include the concepts of the use of warranty to ensure performance decreases risk, transparency is the best way to mitigate risk and risk can be mitigated before it happens. The research revealed that warranty program minimizes the risk for manufacturer and clients and helps differentiates the manufacturer by identifying end users that are not satisfied, applicators that are low performing, jobs that are leaking, customer retention rate and having a running log of satisfaction rating for every warranted job making everything transparent.

Keywords: end user, manufacturer, performance information, risk, warranty

INTRODUCTION

The last couple of decades have revealed a poor documentation of performance information in the construction industry (Cahill and Puybaraud, 1994; CFMA, 2006; Flores and Chase, 2005; Egan, 1998; Davis et. al., 2009). Due to poor documentation, manufacturers and contractors are selling products based on low price and long term warranty durations. The long term warranties have no proven correlation with the performance of a roofing product (Kashiwagi, 2011). The subject manufacturer realized that in order to survive in the competitive market saturated with low price and false promises, they need to differentiate themselves from other manufacturers in a dominant way that will minimize the risk of the manufacturer and the client creating a "win-win" environment.

The subject manufacturer approached the researchers in March 2011 to propose the solutions. The researchers have identified that the contractors, end users and non-transparency are the biggest risk in any construction project. Keeping these issues in mind, researchers proposed a warranty program that tracks the performance information of all the warranties issued by the manufacturer that will track satisfaction ratings from the end users making the system transparent.

Methodology of warranty process:

The manufacturer starts the warranty process by sending a list of all the warranted jobs to the researchers as illustrated in figure 1. After receiving the list of jobs, researchers contact the end users for satisfaction ratings and direct feedback about the job. The questionnaires for the warranty process were developed jointly by the researchers and manufacturers. The subject manufacturer expressed a desire to have an end user satisfaction rating for their product, contractors installing the product, their representative present on the job site and customer retention rate. The researchers agreed that these are the critical elements for a successful roofing job and this would help the manufacturer to clearly identify the unsatisfied end users and mitigate the problem proactively. Keeping these objectives in focus, following questions were developed:

1. Satisfaction rating of the roofing system (1 lowest – 10 highest)
2. Would you purchase the manufacturers product again? (Yes or No)
3. Is the roof currently leaking? (Yes or No)
4. Satisfaction rating of the contractor (1 – 10)
5. Would you hire the contractor again? (Yes or No)
6. Satisfaction rating of the manufacturer's representative (1 – 10)
7. Satisfaction rating of the value relative to the overall project cost (1 – 10)
8. Overall satisfaction rating of the project (1 – 10)
9. Have you used manufacturer's product more than once? (Yes or No)

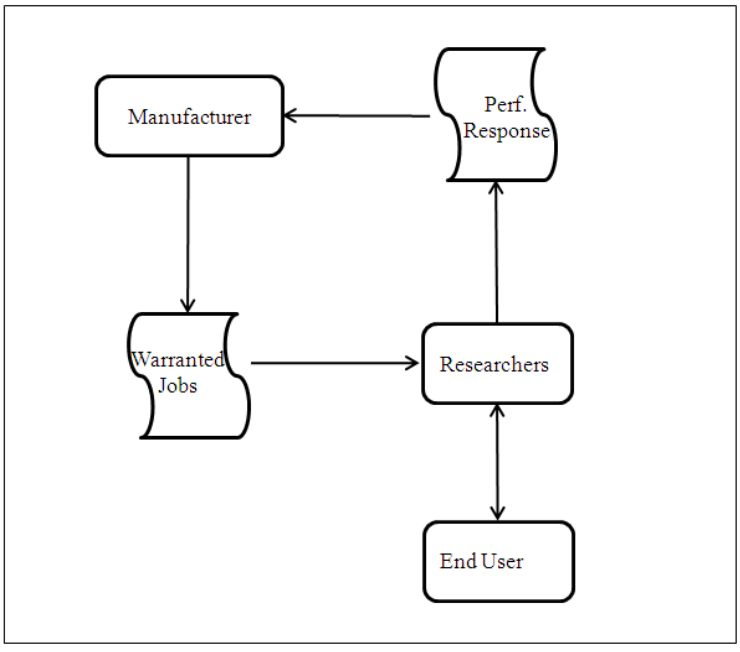

Figure 1: Warranty process

 ISBN: 978-1-84219-840-7 .

Upon completion of the satisfaction check, the performance response (performance information) is then reported back to the manufacturer. This proactive risk minimization system enables the manufacturer to identify and resolve problems upfront, rather than becoming reactive to them as they materialize in the future.

Pilot Projects:
Before advancing any further, researchers recommended the manufacturer to conduct three pilot tests in order to test the ability of the warranty process to accomplish the desired goal of differentiating subject manufacturer from other competitors and minimize the risk:
Pilot 1 - Warranty process on largest and oldest fifty projects
Pilot 2 - Warranty process on randomized one hundred and fifty projects
Pilot 3 - Warranty process on fifty different end user projects

Table 1 shows the performance information of three pilot tests. The data reveals that the overall satisfaction rating of the manufacturer is 9.2 out of 10. The customer satisfaction rating of the roofing system is 9.1 out of 10 and 98% of the customers would purchase the manufacturers product again. There are 99% of the projects with no leaks. However, the customer satisfaction rating of the applicator is below 9.0 indicating it is essential to identify low performing applicators to minimize manufacturer's and end user's risk.

No	Criteria	Unit	Overall	Pilot 1	Pilot 2	Pilot 3
1	Overall customer satisfaction	(1-10)	9.2	8.9	9.1	9.4
2	Oldest job surveyed	Years	3	3	2	2
3	Average age of jobs surveyed	Years	1	1	1	1
4	Customer Satisfaction - Roofing System	(1-10)	9.1	8.9	9.1	9.3
5	Percent of customers that would purchase the system again	%	98%	100%	97%	100%
6	Percent of roofs with no current leaks	%	99%	98%	99%	100%
7	Customer Satisfaction – Contractor	(1-10)	8.8	8.7	8.9	8.7
8	Percent of customers that would hire same Contractor again	%	95%	98%	97%	100%
9	Customer Satisfaction – Manufacturers Representative	(1-10)	9.5	9.2	9.6	9.5
10	Customer Satisfaction - Value relative to project cost	(1-10)	8.9	8.7	8.9	8.9
11	Percent of repeat customers (surveyed)	%	N/A	N/A	N/A	77%
12	Total job area (of job surveyed)	SF	4,942,175	3,202,636	1,125,333	614,206
13	Total number of jobs surveyed	#	127	31	76	20
14	Total number of surveys	#	250	50	150	50

Table 1: Performance information for pilot tests

 ISBN: 978-1-84219-840-7 .

Table 2 shows the percent of end users that can be contacted and the reason if they were not being contacted. The research revealed that only 52% of the end users could be contacted.

No	Criteria	Unit	Overall	50 Projects	150 Projects	50 Diff Projects
1	Bad/Missing Information (No contact info, wrong #, etc.)	%	28.4%	34.0%	26.0%	30.0%
2	Refusal to Complete	%	2.0%	2.0%	0.7%	6.0%
3	Jobs cannot be contacted	%	15.4%	2.0%	22.6%	24.0%
4	Surveys Returned	%	51.8%	62.0%	50.6%	40.0%

Table 2: Survey responses

Since end users play a critical role in the warranty process, it is essential that the response rate of the end users to increase. Manufacturers and the researchers agreed that the warranty process needed a twitch in order to meet its purpose to increase the response rate of the end users.

New warranty process

Upon addressing this issue to the manufacturer, it was revealed that the contact information was provided by the regional managers on the field and that they did not realize the importance of accurate contact information in the warranty process. In order to ensure the smooth functioning of the warranty process system it was identified that following is important:

1. The education within the organization
2. Warranted jobs submitted monthly to minimize the time between job completion and satisfaction check
3. Send a monthly list of jobs that cannot be contacted to the regional manager and request the accurate contact information

Figure 2 illustrates the updated warranty process. The difference compared to the previous process is that if the end user cannot be contacted, regional manager is responsible for providing the accurate contact information. After the accurate contact information is received, the end user is contacted again for the performance response.

 ISBN: 978-1-84219-840-7 .

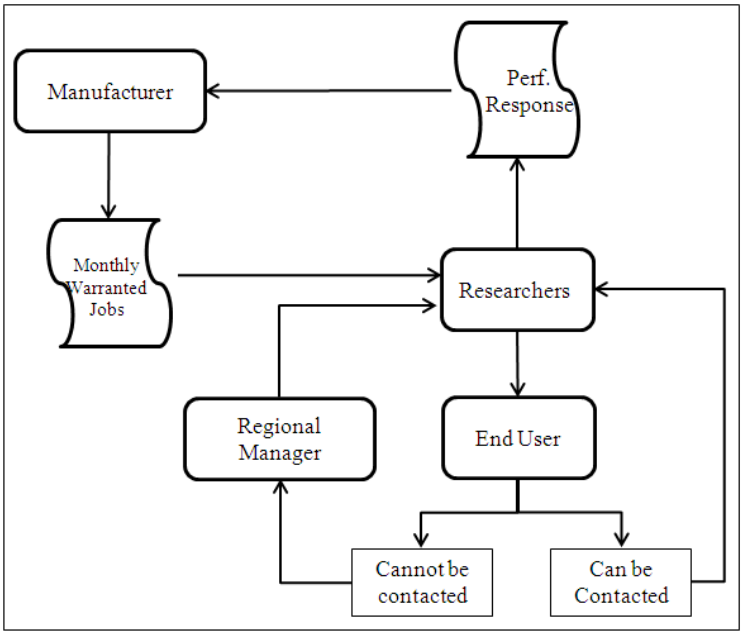

Figure 2: Updated warranty process

The new warranty process is being implemented since April 2012. Two regional managers have been trained on the warranty process. The end users for monthly list of warranties for April 2012 have been contacted. Table 3 reveals the performance information of jobs warranted in April 2012. The data is consistent with the pilot tests where the applicator is the source of risk to manufacturer due to low rating (8.7 out of 10). Roofing system and percent of customers that would use the manufacturer's product again is high. The overall customer satisfaction rating is 9 out of 10. It was identified that two of the roofs (5%) were leaking. The customer retention rate and percent of customers that would purchase manufacturers product again was high with 84% and 97% respectively.

No	Criteria	Unit	April 2012
1	Overall customer satisfaction	(1-10)	9.0
2	Oldest job surveyed	Years	2
3	Average age of jobs surveyed	Years	1
4	Customer Satisfaction - Roofing System	(1-10)	9.2
5	Percent of customers that would purchase the system again	%	97%
6	Percent of roofs with no current leaks	%	95%
7	Customer Satisfaction – Contractor	(1-10)	8.7
8	Percent of customers that would hire same Contractor again	%	84%
9	Customer Satisfaction – Manufacturers Representative	(1-10)	9.4
10	Customer Satisfaction - Value relative to project cost	(1-10)	8.8
11	Percent of repeat customers (surveyed)	%	84%

12	Total job area (of job surveyed)	SF	607,522
13	Total number of jobs surveyed	#	37
14	Total number of surveys	#	107

Table 3: Performance information for warranted jobs in April 2012

Table 4 shows that almost half of the clients are non-responsive due to incorrect contact information. The list of jobs that do not have accurate contact information are being sent to the regional manager's. Upon receipt of the updated list, the end users will be contacted again increasing the response rate.

No	Criteria	Unit	CURRENT
1	Bad/Missing Information (No contact info, wrong #, etc.)	%	15.1%
2	Refusal to Complete	%	0.9%
3	Cannot be Contacted	%	49.1%
4	Surveys Returned	%	34.9%

Table 4: Survey response for April 2012

CONCLUSION

The manufacturer was successfully able to implement the warranty program and measure the performance information of their systems and applicators as directed by the researchers. Having a documented performance proof of the performance of their systems differentiates the subject manufacturer from other competitors. The warranty program also benefited the manufacturer to minimize the risk not only for manufacturer, but also for the end users by identifying end users that are not satisfied, applicators that are low performing and having a running log of satisfaction rating for every warranted job. The manufacturer was able to mitigate the risk proactively by identifying the unsatisfied end user and leaking jobs in the warranty process.

The research also revealed that the product of the manufacturer is a high performing product. The contractor installing the product for the manufacturer was a source of risk to the manufacturer.

ABSTRACT

The main objective of the research was to investigate and identify the shortcomings that exist within the current mechanisms to limit financial risks so as to develop a new method that can be used to eliminate construction cost overruns in South Africa due to delays. The study sought the views from a variety of construction professionals within their own organisations on persistent cost overruns caused by construction delays. Registered and experienced construction consultants who have practised for over ten years which include; architects, quantity surveyors, engineers, various construction professionals employed by Medium to Large Contractors, representatives from Municipal Councils and the Ministry of Public Works were selected for the survey. The research adopted qualitative and quantitative methods which allowed the use of a comprehensive literature review and questionnaire survey to gather both secondary and primary data. The respondents' responses were analysed by use of simple descriptive statistics. The findings and results of the research were used to develop new mechanisms aimed at limiting the impact of financial risks and disputes. The research is aimed at adding more value to the industry if implemented by eliminating the persistent cost overruns caused by delays which cannot be managed by existing mechanisms.

Key words: contracts, construction delays, cost overruns, mechanisms, risks.

INTRODUCTION

The study focuses on the causes and effects of delays in-order to find out the risk impact of cost overruns in construction contracts. According to Aibinu and Jagboro (2002:593-599) a delay in construction is a situation whereby the contractor and or the project owner contribute to the non-completion of the project within the original or the stipulated or agreed contract period. Clause 29 of the JBCC Principal Building Agreement (2007:20) and the General Conditions for Construction Works (2008:25) give the contractor a right to apply for the revision of dates for practical completion due to delays caused by the employer. Kaming, et al. (1997: 830) generally agrees that the predominant causes of delays are; design changes, poor labour productivity and inadequate planning. Doran, et al. (1994:254-260) highlighted the important causes of delays as poor financing of projects and late payment for work in progress, poor contract management, changes in site conditions and shortages in materials in general. Duncan (2009:362) classifies the causes of delays as project participants and extraneous factors. He identified client-related delays as variation orders, slow decision-making and cash flow problems while contractor-related delays included financial difficulties, material management problems, planning and scheduling problems, inadequate site inspection, equipment management problems and shortage of manpower. They further identified extraneous causes of delays as inclement weather; Acts of God, labour disputes and strikes.

Client related delays

According to Duncan (2009:362) delays caused by the employer, his/her agents or directly employed contractors happen when work fails to be completed on time because the architect or some other member of the design team has failed to provide information requested by the contractor on time, or sub-contractors employed directly by the employer disrupt the main constructor's work programme. He contended that in such a case the contract would be extended and in some cases would be classified as a 'relevant event' which gives grounds for a claim of additional costs to the contractor for delays caused by the employer. Battain and Odeh (2002:67-71) found that that the most important delay risk factors are financial difficulties, late payment for works in progress, owners interference and slow owner's decision-making process. Wanyona (2004:298) found that there is limited formal application of financial risk management in cost planning and control. He further identified issues which have a significant impact on financial planning of buildings to be; the nature of price data, the accuracy of the cost advice, potentials to assess building costs, implementation of risk analysis techniques, cost impact on the budget, frequency of financial risk occurrence, the typical response to financial risk, risk management in building budget, communication of the likely cost impacts and current problems of financial risk planning and management of building projects. The main causes for payment delays in the construction industry as; delays in certification, paymaster's poor financial management, local/cultural attitude, paymaster's failure to implement good governance in business, underpayment of certified amounts by the paymaster and abuse of the use of "pay when paid" clauses in contracts (Danuri, et al. 2005:613-623). Abdul et al. (2006) conducted a survey of top management of construction companies in Malaysia and confirmed that financial problems are the main causes of delays in addition to manpower shortage. Construction payment problems have domino effects on the payment chain of construction projects since late payment due to

the contractor by the employer will also delay the payment due to the sub-contractor or suppliers who are bound in contract with him. Buys (2006:119) pointed out reasons for late payments as; either the Project Quantity Surveyor not providing the Principal Agent with the necessary payment information on time; or the Principal Agent being late in issuing the payment certificate; or the employer delaying the payment.

Contractor related delays

These include; inadequate experience, construction errors, poor site management and supervision, equipment failures or allocation problems, inadequate labour skills, site manager lacking authority, improper planning and scheduling, inaccurate estimation and poor contract management according to (Lim and Mohamed 2000:267-273). Duncan (2009:362) explains that delay caused by the contractor is a situation where the contractor fails perhaps due to a combination of lack of expertise such as labour and management skills; and so fails to complete the work on time. He adds that under these circumstances, the contractor has no real excuse for failure to complete and can expect to pay the full amount of the damages for causing delays as stated in the contract. Odeh and Battaineh (2002:67-73) indicated that inadequate contractor experience is an important factor that could be linked to the most common contract awarding procedure that is based on the tradition that the project is awarded to the lowest bidder. Zietzman (2004:105) acknowledges that all errors in the construction industry are caused by human. He continues to add that human error is very common place in human beings' lives and almost everybody makes errors from time to time while technical errors found in the physical setting out of an activity occur when a person fails to carry out a procedure and are relatively easy to identify. Zietzman (2004:105) maintain that a human can always make errors at any time regardless of the level of skill, experience or training they have. He defines errors as human action that exceeds some limit of acceptability or some allowable tolerance, a performance that deviates from the acceptable standard of practice and, a departure from acceptable or desirable practice on the part of an individual that can result in an unacceptable or undesirable result. Kanagasabapathi and Ananthanarayanam, (2005:34) have pointed out that site managers should be responsible for scheduling the activities of individual projects while the resource pool managers should be responsible for allocating the resources to the projects. Smallwood, (2006:64) points out three tasks of management as: managing a business; managing managers; and managing worker and work. He contends that although the three jobs can be analyzed separately, studied separately, appraised separately, and despite each having a present and a future dimension, management cannot separate them nor can it separate decisions on present from decisions on future. He further stated that a management leader who specializes in all the functions undergoes a systematic use of classified knowledge, concepts, principles and a common vocabulary, and who subscribes to the standards of practice and a code of ethics established by a recognized body.

Sambasivan and Soon, (2006:23) observed that many of the contractors do not own the equipments that are required for the construction work and only rent the equipments when required. They further contend that during the season when there are many construction projects, the equipments are in short supply and are poorly maintained which lead to failure of the equipment causing the progress to be hampered thereby

causing delays to the construction work. Edwards, Holt and Harris (1998:25-37) found that the construction industry relies increasing on profits generated from high utilization of mechanization, but the interruption of the mechanical supply or poor allocation not only incurs the tangible costs of labour, replacement parts and consumables but also the less tangible costs of delays to contract, possible loss to clients' goodwill and loss of profit. Lack of financial resources in education, loss of previously established facilities and staff, and a philosophy that industry should train its own employees in South Africa, denies the reality of a fragmented industry using casual labour (English and Summerville, 2004:20). Gann and Senker (1998:569-580) contended that the type of skills acquired is equally important though the current environment may not support entrepreneurship or innovation, which is required to sustain long-term performance improvements.

Fryer (2004:70) identified the three broad classes of skills as: human, technical and conceptual. He added that human skill is the managers' ability to work as a group member and build co-operative effort in the team, communicate and persuade. Technical skill includes proficiency in some aspect of the organizations work, analytical abilities and specialized knowledge. A good estimator can readily estimate the cost of a project in his area of operation, but it may not always be so for projects outside his area of operation. While cost engineers, quantity surveyors and project managers are generally familiar with the major sources of cost data in their areas of operation, they are often unaware of useful sources of cost data and related information in other areas. Buys (2006:118) investigated various methods for calculating the value of interim claims: these include accurate measurements conducted on site or rough estimates of quantities taken on site. Estimating is seen as the technical process of predicting the cost of construction. It involves the building up of rates for building elements and components based on the cost of labour, material and plant (Oladapo, Aladegbaiye and Aibinu, 2006:108-109). According to Okumbe (2009:39), the construction contract is the most critical element in the construction project because it defines the contractor's scope or work and compensation. Contract performance includes the obligation to complete the work, maintenance and defect issues, time for completion, prices, and damages (Ling and Low 2007: 240).

Consultant related delays

Preparation and approval of drawings were identified by Arditi and Gunaydin, (1998:194-203) while design errors, delays in work approval and uncompromising attitude have also been cited by Odeh and Battaineh (2002:67-71). Sambasivan and Soon (2006:27) have cautioned consultants that, when preparing the contract between the client and contractor, they should include items such as duration of contract, mechanisms to assess the causes of delay, prepare risk management plans, prepare and approve drawings on time and monitor the work closely by making inspections at appropriate times. Swain and Guttmann cited in Zietzman (2004:105) have classified errors as; time errors, qualitative errors, sequence errors and quantitative errors. He further identified common causes of human errors in the construction industry as incomplete understanding of the structural behavior and design criteria, poor judgment and problem overlooking, calculation errors, contractors' interpretation of the design and drawing to his own advantage, organizational problem, adaptation of information from different sources

without full understanding, specification ambiguity, in-experience of engineers, designers, inspectors of works, poor inspection or no regulations to provide good inspection, co-ordination deficiency between involved parties, time pressure, incomplete design and ignorance of some important and relevant characteristics. Owners' attitude could lead to diverse variables such as excessive requests of an owner, accuracy of bidding documents, quality of technical specifications and standards, owner's management ability, fairness of owner's representative, possibility of owners' payment delays or repudiation, and owner's funding capability (Kim, et al. 2008: 409).

Project attributes related problems

These are adverse factors such as unforeseen site conditions, a confined site, problems caused by neighbours such environmental pollution, unrealistic imposed contract duration, inaccuracy of project information (Ling and Lau, 2002:413-423). Kim, et al. (2008: 409) argues that sudden exceptionally inclement weather may also cause delays if it was not anticipated and therefore was not incorporated in the original contract program. They add that the physical project environment in all characteristics that define the technical nature of project characteristics and contractual conditions relates to the variables such as site conditions and climate. These variables include; differing subsurface conditions, accessibility to the site, availability of basic infrastructure in the surroundings of the site, level of community agreement with the need for investing in the project, weather conditions and influences of force majeure and the technical complexity of the project. Project duration is defined as the entire project cycle from conceptual design (after business planning) through start-up up to practical completion (David, Stuart, Andrew and Rodrigo 2004: 33). There are possible interventions caused by adjacent sites, potential delays in commissioning, conditions of material delivery, stock and assembly of resources, skillfulness of labourers and level of owners intervention in selecting local subcontractors and possible delays in project permission, (Kim, et al. 2008 : 409).

Co-ordination-related problems

Zhi (1995:231-235) identified poor communication, excessive use of subcontractors and nominated suppliers, excessive bureaucracy, fraudulent practices and kickbacks, misalignment of client's expectations and jurisdictional disputes. PMBOK (2000:17) defines project communication management as the processes required to ensure timely and appropriate generation, collection, dissemination, storage and ultimate disposition of project information. It comprises communication planning, information distribution, performance reporting and administrative closure. Emmitt and Gorse (2003) have defined communication as artifacts that add to the sum of knowledge on particular issues or more philosophically as environmental occurrences that have the potential to become sensory signals. Construction information tends to be varied and easily assumes the form of drawings, models, specifications, post data, and program schedules along other designs and management information required for the successful completion of a building assignment (Emmit and Gorse 2003 cited in Mutunga and Talukhaba 2004:190). Bowen, et al. (2006:22) defines briefing as an informative process by which the needs and desires of the client are communicated to others either officially or unofficially. A high degree of sub-contracting may lead to high risk of delays and this could cause inefficiencies in the

construction industry (Sambasivan and Soon, 2006:23). The tender evaluation method used is critical to the success of the project because it strongly affects the subsequent outcome of the project. It is traditional to select the contractor with the lowest bid after the process of pre-qualification which is based on the assumption that the pre-qualification exercise eliminates all incompetent contractors and guarantees that a pre-qualified lowest bidder will successfully execute the project, (Oladapo and Odeyinka, 2006:109). Kim, et al. (2008: 409) have stressed the importance of fairness and stability of construction laws and regulations, extent of corruption, stability of social situation, and any restriction on profit transfer specifically for oversees projects. Construction risks include social, political, economic, financial, legal, health, managerial, technical and cultural risks (Ling and Low 2007: 238). They further contended legal risk entails issues such as breach of contract by project partners or other participants, lack of enforcement of legal judgment when problems arise, insufficient law for joint ventures, uncertainty and unfairness of court justice and insolvency of a partner. Duncan (2009:362) explains that environmental related delays are caused by circumstances outside the control of either the contractor or the employer, for example exceptionally inclement weather and force majeure. Assaf, et al. (1995:45-50) found that the risks of environmental related delays are caused by natural conditions which includes inclement weather or socio-economic conditions leading to material shortage or late delivery, labour shortage and price fluctuations which do cause risks of delays in construction projects. Examples are inconsistent policies, and slow government permits, (Assaf, et al.1995:45-50). Sambasivan and Soon (2006:23) found that shortages in basic materials like sand, cement, stones, bricks, and iron can cause major delays in projects. According to Ling and Low (2007:241), enactment and formulation of new regulations and policies frequently do make it difficult to keep up with the changes.

Effects of delays in the construction industry

Aibinu and Jagboro (2002:39-46) found that delays can also result in time overruns, cost overruns, disputes, arbitration, total abandonment and protracted litigation by the parties. A project that is completed late bears the risk of causing damages to the client and the contractor (Yusif and Odeyinka 2003:105). Sambasivan and Soon (2007:25) survey found that factors such as inadequate planning by the contractors, inadequate project handling, experience of contractors, and delay in the payments for the work completed directly affect the completion of the project and cause time overruns. Yusif and Odeyinka (2003:104) have contended that the requirement to reduce cost overruns has become very critical for the governments of most developing countries including Nigeria where public funds have been dwindling over many years of economic decline. In most instances, time overrun leads to cost overruns and disputes. Dispute resolution procedures are highlighted in the JBCC Principal Building Agreement (2007:32-33) and the General Conditions of Contract for Construction Works (2008:42-46) which appears to be very involving and costly. According to Okumbe (2009:41), arbitration is the reference of a dispute or difference between not less than two persons for determination after hearing both sides in a judicial manner by another person or persons, other than a court of competent jurisdiction. Sambasivan and Soon (2006:25) concede that client related and contract relationship related factors escalate disputes to be settled by an arbitration process by engaging a competent third party that can settle the disputes amicably without

going to the courts. Malbex (2005:1-8) found that many projects were temporarily abandoned during the financial crisis between 1997 and 2000 which made the project promoters to back out because of poor cash flow and economic conditions. Litigation is an alternative dispute resolution method whereby the disputant initiates legal action against the other party by going to court (Agarwal 2001) and is normally used when all other avenues have failed.

PROBLEM STATEMENT

The research intends to formulate formal initiatives to find out what can be done to develop a new project governance management structure that can be used to avoid the unexpected construction cost overruns due to contract delays. The problem is that even with the provisions of relevant clauses which allows for extension of time in most construction contracts to manage delays the construction industry still encounter the risks of unbudgeted cost overruns.

METHODOLOGY

The research gathered comprehensive information from reliable different groups of stakeholders selected at random for the survey to find out the key causes and effects of delays in order to propose a new mechanism based on the views from the respondents. The research adopted a combined technique which allowed the used of qualitative and quantitative methods for the investigation. Descriptive and analytical survey methods which allowed the use of questionnaires to obtain data were adopted to meet the research objectives. Out of the 173 total number of the questionnaires distributed, 91 were returned and found to be properly answered and suitable for analysis. The study recorded a response rate of 52, 60% which Emerald (2003:2), agree that 50% response rate is reliable for research of this nature. The study was conducted amongst qualified registered professionals and experienced stakeholders in the South African construction industry who have practised for over ten years. A research conducted by Oladapo and Akindele (2006) also supports the reliability of the choice of qualified professionals and experienced stakeholders with over ten years experience for a research of this nature.

RESULTS AND DATA INTERPRETATION

The data gathered to achieve the results were analyzed by use of simple descriptive statistics namely frequencies and percentages as shown in the corresponding tables and figures.

Site conditions and inclement weather	**72,46**	**Extension of time without costs**

Table 4: Other effects of delays

Identification of the Key delays:

The key causes of delays are presented in Table 1 and their corresponding figure 1 as shown. Table 1 shows various causes of delays against the responsible identified construction parties based on indications from the respondents on the key causes of delays. Table 1 is divided into three columns where column 1 shows a list of responsible parties and their identified causes of delays. Column 2 of Table 1 shows the results in percentages for each cause of delays. Column 3 shows the identification of key causes of delays for each responsible party by indicating with a tick for results which are over 50%. The Tables therefore categorizes the different causes of delays and responsible parties as Owner/Client/Employer related, Contractor related, Consultant related and Government

related. Tables 2 through to 4 show the effects due to the causes of delays in terms of time and costs. The first columns in all tables show a list of delays and parties responsible for causing delays. The second column shows the effect on a particular cause of delay in percentage from the responses. The third column shows the interpretation of the effect on a particular cause of a delay. The percentages were generated on data analysis based on the averages from the respondents. An indication of 50% was considered a key effect of delay. After analyzing Table 1, based on the identification of causes of delays and their responsible parties and the effects of delays, the main risks of key causes of delays were ranked from the highest to the lowest in each category as shown and presented in Figure 2. The identification of responsible parties as well as types of delays is shown in Table 1. The parties responsible were identified as the Owner, Contractor, Consultant and Government. On the other hand, the types of delays, which were already explained in literature review, are classified as:

- No extension of time with costs : The contractor gets no extended completion period or money;
- Extension of time without costs: The contractor gets only extended completion period but no money;
- Extension of time with costs: The contractor gets both extended completion period and money;
- Concurrent: The contractor may or may not get either extended contract period or money.

Out of the causes of delays presented in Table 1, only three causes, namely financial process, payments delays and economic problems were identified as client based delays without any key delay identified. This is alluding to the fact that the three causes of delays identified are all lower than 50%. The results also show that the contractor does not get extension of time or money for any delays caused by the client due to financial process, economic problems and payment delays. It is important to note that all these factors do cause delays generally to construction projects and more so affect the contractor as been identified in the literature review chapters. About eleven factors have been identified as contractors causes of delays of which nine are “key” in this category. The key causes of delays ranges between 51%, 89% and 87, 98%. Even for the key causes of delays contractors are still at risk of not given extension of time with costs since there is no key effect of delays identified in table 2. According to the literature review contractor related delays are considered to be given no extension of time and without costs. The contractor may be at risk for the imposition of penalty charges should he fail to accelerate the works to practical completion date as stipulated in the different types of contracts identified in the literature review. Unbearable penalty charges imposed on to contractors could lead to contract termination, liquidation, total abandonment and disputes hence should be avoided at an early stage of the contract.

Based on the causes of delays presented in table 1, five causes have been identified as consultant based delays of which all of the five were found to be key causes of delays which range between 52%, 53% and 87, 78%. It has been observed that contractors are awarded extension of time with costs for only two out of the five key causes of delays as presented in Table 3 notably construction errors and design errors.

Six causes have been identified as Government caused delays based on presentation in table 1 of which only two were found to be key causes of delays. The key causes of delays are 55, 70% and 73, 74% as indicated by the respondents. It has been observed that contractors are awarded extension of time with costs for only one out of the two key causes of delays as presented in Table 4. Jurisdictional disputes and inconsistent policies were not considered key by the respondents since they are both rated lower than 50%. Other causes of delays were identified as site conditions and inclement weather which respondents responded with 82, 22. Table 5 shows that contractors are awarded extension of time without costs due to delays caused by site conditions and inclement weather since respondents responded with a response rate of 72,46%.

CONCLUSION

Unexpected cost overruns can only be limited and avoided when their causes are fully identified. It is imperative that when causes of unexpected cost overruns of a particular group are known, investigated and possible solutions to control them are eventually realized then perhaps similar methods can be used in avoiding the same. The research found that out of a total number of the sixteen key causes of delays identified, Contractors' related delay is the most critical since it had nine key causes, followed by Consultant related with five key causes of delays, Government had two key causes and lastly Client/Owner who had no key cause of any delay. In general the sixteen most critical causes of delays across the four sub-headings in order of their magnitude are; Inadequate experience, design errors, Inadequate labour skills, Poor site management and supervision, Equipment failure and or allocation, Uncompromising attitude, Site management lacking authority, Inconsistent policies, Improper planning and scheduling, Excessive use of sub-contractors, Material shortage and late delivery, Inaccurate estimation, Lack of communication and project information, Excessive bureaucracy, Construction errors caused by errors in contract documents and Poor contract administration. Contractors are only granted extension of time with costs due to construction errors emanating from design errors and poor contract administration caused by consultants; labour disputes and permits caused by government. Contractors are neither awarded extension of time or money for the delays caused by client and contractors. It was also found from the study that all the proposed new mechanisms from the survey had an average response rate of 86.58% stating that they should be adopted in an effort to reduce the impact of financial risks caused by construction delays.

RECOMMENDATIONS

Based on the findings of this study the research further recommends the development of new mechanisms to limit the impact of existing financial risks in the South African construction industry. The mechanism can be used as a project governance management structure to reduce the risk of unexpected cost overruns caused by delays, stakeholders should ensure the following:

- Adequate and available sources of finance from project inception to completion to avoid project and payment delays;
- Avoid construction errors by employing experienced personnel;
- Use proper and modern construction equipment and maintain them regularly according to manufacturers' instructions;

- Adequate labour and training facilities in the market to meet the industry changing needs;
- Availability of competent and proper site management authority, proper project planning and scheduling;
- Accurate initial time, cost estimation and proper contract management are conducted by providing complete information as required;
- Competent consultant who will avoid design errors, engage in community involvement, elimination of uncompromising attitudes and ensure adequate investigation of site conditions;
- Accurate initial time estimates;
- Adequate labour in the market for construction works;
- All building related permits are done on time;
- Proper co-ordination amongst personnel, shall provide clear information and communication channels and who will avoid excessive use of sub-contractors;
- Discourage excessive bureaucracy, fraudulent practices, kickbacks and eliminate jurisdictional disputes;
- Projecting realistic contract duration, ensure that there is sufficient manpower in the market to cope with their designs and obtain permits in time before the commencement of the project;
- Develop proper co-ordination guideline structure right from the project inception stage until project completion;
- Mediation should be enforced in construction contracts by allocating time frame for its process since it has been found to the most acceptable and cheaper dispute resolution procedure used internationally.

REGRESSION MODELLING OF RISK IMPACTS ON THE VARIABILITY BETWEEN CONTRACT SUM AND FINAL ACCOUNT IN TRADITIONAL PROCUREMENT

Henry Odeyinka[1] and Keren Larkin[2]

[1&2]*School of the Built Environment, University of Ulster, Jordanstown, Belfast BT37 0QB, UK*

ABSTRACT

The Bill of Quantities (BOQ) has been used for so long in traditional procurement. However, it has also been a subject of criticism with the critics questioning its reliability in predicting construction cost, especially as the out turn cost of many construction projects end up being at variance with the contract sum predicted using the BOQ. It is the contention in this study that it is rather the risk factors normally inherent in any construction project that are responsible for the observed variability. A two- stage approach to data collection was adopted. The first was a UK wide online survey aimed at determining the significant risk factors to focus on for modelling purpose. The second involved the collection of case study data. The analysis result from the first stage of data collection and the data set from the second stage were used to develop multiple linear regression (MLR) models for assessing risk impacts on the variability between contract sum and final account. Result of the developed model showed the potential for risk/ impact modelling and it also revealed that the relationship is not strictly linear.

Keywords: cognitive model, contract sum, final account, risk factors, regression modelling.

INTRODUCTION

Many writers and researchers have reported an observed decline in the number of contracts based on BOQ in the UK and Australia over the past 20 years. In spite of this, Davis *et. al.* (2009) maintained that the BOQ remains unsurpassed as a model on which to obtain bids and that it is a very useful tool for post contract cost control. Pheng and Ming (1997) are some of the critics of the BOQ, claiming among other things, its lack of precision in predicting building cost.

In a previous study conducted by Odeyinka *et. al* (2009) the budgetary reliability of the BOQ in procuring building projects was investigated using secondary data from completed building projects in the UK. The study concluded that in traditional procurement where bills of quantities were used to ensure cost certainty, deviations between the contract sum in the BOQ and final account figures were still observable.

[1] h.odeyinka@ulster.ac.uk

[2] ki-larkin@email.ulster.ac.uk

The conjecture being explored in the present study is that instead of criticizing the reliability of the BOQ, risk factors normally inherent in every construction project is responsible for the observed deviation between the contract sum and final account. The objectives of the study are two-fold, first to identify and prioritize the risk factors impacting construction cost in traditional procurement. Second, to develop and validate models for assessing risk impacts on the variability between contract sum and final account. It is envisaged that the developed models will facilitate a pro active approach to managing risk impact on construction cost.

LITERATURE REVIEW

Traditional Procurement and Risk

Winch (2010) submitted that there are usually observed differences between the contract sum and final account due to factors which are not only hard to predict but difficult to manage. Morris and Hough (1991) are of the opinion that cost overruns are caused by circumstances which are outside of the project's area of control. According to them, many projects overrun on cost for various reasons and therefore an important issue is the ability to predict such factors and the impact they will have on the project. Love et al. (2011) for instance attempted to determine the intermediary events and actions that contribute to cost overruns in social infrastructure projects. Whilst the attempt is laudable, its main focus on design error is considered limiting. As such, this study looks further to other risk factors potentially responsible for cost overruns.

Fig. 1 illustrates the 'speculative' risk to a client and contractor for specific procurement methods. Speculative risk is that which can be apportioned in advance of the project as decided by the parties in the contract (Davis *et al.* 2009). As illustrated in Fig. 1, speculative risk can wholly lie with the employer or the contractor depending on the procurement method selected. Under the traditional forms of procurement which is the focus of this study, it is evident that the more definite the BOQ is before contract award, the less is the speculative risk retained by the employer.

Fig. 1: Risk Apportionment between Client and Contractor

 ISBN: 978-1-84219-840-7 .

Risk perspective

The UK based Association for Project Management (APM) defines risk as ‘an uncertain event or set of circumstances that, should it occur, will have an effect on the achievement of one or more project objectives.’ (APM 2006). This definition takes into account the fact that the effect on project objectives could be either negative or positive. The US based Project Management Institute (PMI) defines risk as 'an uncertain event or condition that, if it occurs will have either a positive or negative effect on one or more of the project’s objectives', which are usually cost, time, scope and quality (PMI 2008). Some earlier definitions of risk tend to focus on the negative impacts alone. For instance Wideman (1986) defines project risk ``as the chance of certain occurrences adversely affecting project objectives". According to him risk commonly carries largely negative associations of loss or harm which generally has implications of negative or adverse effects from an uncertain event.

The definition of risk provided by APM and PMI which consider both the positive and

negative impacts of the occurrence of uncertain events is embraced in this study. However, Winch (2010) provided further illumination to risk definition offered by PMI and APM contesting that in common practice, risk is only used to refer to the probability of a detrimental effect, with the word reward being used to signify the probability of a beneficial event occurring. In order to connect with the real world, the common practice usage of the word risk has been embraced in this study to refer to the probability of a detrimental effect. This defines the premise of this research and it is our view that by minimising risk occurrence and detrimental impacts, the benefit of positive impacts will also be realised.

Winch (2010) uses the cognitive approach to partition the 'risk space' into four compartments depending on whether the occurrence of any event is either certain, impossible or somewhere in between the two. As shown in Fig 2, this approach makes a clear distinction between when a probability distribution can be assigned to the occurrence of an event and the condition where it is not possible to assign a probability distribution due to the amount of information available per time.

The cognitive model of risk (Winch, 2010) has been explored in this study to uncover the underlying risk variables impacting the variability between contract sum and final account. Using the Joint Contract Tribunal’s [JCT] (2005) Standard Form of Building Contract with Quantities [SBC/Q] and discussion with construction professionals, some of the risk factors identified include; variations by the client, change in design by client, change in scope of works, unexpected site conditions and change in design by the Architect. Others include; problems arising due to client's lack of experience, inadequate specification, extremely competitive tender, third party delays, defects in design, delay in resolving disputes, delay in nominated/ named material supplier, underestimation of quantities, local concerns and requirements, contract document conflicts, project funding problems, ambiguous contract terms, loss or damage by fire or flood.

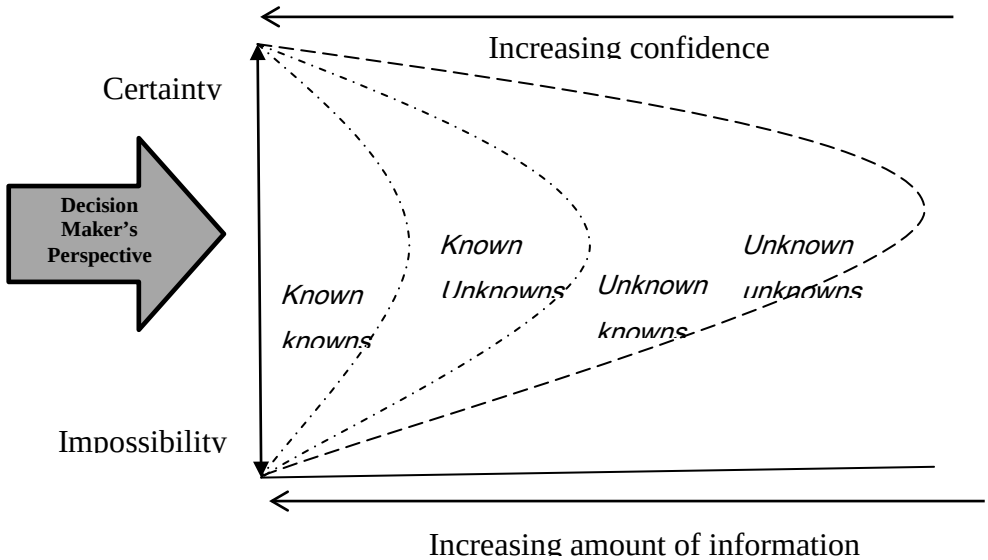

Fig. 2: A Cognitive Model of Risk

Source: Winch 2010

RESEARCH METHODS

A two-stage approach was adopted in data collection. The first was an online questionnaire survey of risk factors thought to impact the variability between contract sum and final account in traditional procurement. Data for the first stage were sourced from UK based Private Quantity Surveyors (PQS), Contractors' Quantity Surveyors, Architects and Project Managers (Table 1). A stratified random sampling approach was adopted whereby the sampling frame was drawn from available databases. In order to satisfy research ethics, a total of 348 potential respondents were emailed enquiring whether they were willing to complete an online questionnaire for the purpose of this research. Out of these, 62 replied that they were willing to complete a questionnaire. In all, 43 completed responses were received, which translates to a response rate of 69.35%. The designation of the respondents is shown in Table 1 with mean years of experience of 26.05 and standard deviation of 12.17. Using the cognitive model of risk presented in Fig. 1, it was decided to explore the domain of objective risk at project level where it will be possible for construction practitioners to provide opinion based on their experience (known known risk category).

Table 1: Designation of Respondents

Designation	Frequency	Percent	Cumulative Percent
Architect	11	25.58	25.58
Client's QS	21	48.84	74.42
Contractor's QS	6	13.95	88.37
Project Manager	5	11.63	100.00
Total	43	100.00	

Mean years of experience: 26.05 and Standard deviation: 12.17

In all, a total of 18 risk factors thought to potentially influence the variability between contract sum and final account were identified both from literature and also from

discussion with construction professionals. Using a two-dimensional scaling, respondents were requested to score on a Likert –type scale of 0-5, the extent of occurrence of the identified risk factors and their perceived impacts in case of occurrence. This then gives the measuring scale the property of an interval scale, which makes the collected data suitable for various statistical analyses.

Responses to the questionnaire survey were analysed using the mean ranking analysis to determine the relative importance of the risk factors considered. The mean score is determined as follows:

$$MeanScore = \frac{5n_5 + 4n_4 + 3n_3 + 2n_2 + 1n_1 + 0n_0}{(n_5 + n_4 + n_3 + n_2 + n_1 + n_0)} \quad \text{(Equation 1)}$$

Where: n_0, n_1, n_2, n_3, n_4 *and* n_5 are the number of respondents who scored the responses as 0, 1, 2, 3, 4 and 5 respectively.

Table 2 summarises the result of the mean ranking analysis for both the extent of risk occurrence and impacts of occurrence. In addition, the degree of risk was calculated by multiplying the extent of risk occurrence by risk impacts. This helps to determine the significant risk impacts to focus modelling attention on. Using PMI's (2008) risk matrix method of categorising risks, the top 5 risk factors in Table 2 came up as the significant risk factors to consider for modelling.

The second stage of the data collection involved the collection of contract sum and final account data from selected case study projects. These pair of data sets was used to determine the percentage variation between contract sum and final account. This then constitutes the dependent variable for modelling purpose. The case study projects were new build commercial projects of similar size and approximately similar construction cost. Project Quantity Surveyors who worked on the case study projects were also requested to score on a Likert-type scale, the extent of occurrence of the identified significant risk factors. This then constitute the independent variables for modelling purpose. The dependent and independent variables were then used to model risk impacts on the variability between contract sum and final account using multi linear regression (MLR) modelling method.

REGRESSION MODELLING

Using the MLR modelling method, the two sets of data collected as dependent and independent variables were combined for model development. Table 3 shows the regression coefficients obtained using the Statistical Package for Social Sciences (SPSS). Equation 2 shows the regression model obtained from the regression coefficients.

$$Y_{var} = -0.047 + 0.042X_1 - 0.035X_2 - 0.06X_3 + 0.029X_4 - 0.029X_5 \quad \text{(Equation 2)}$$

Where Y_{var} is the percentage variation between contract sum and final account
X1, X2… X5 are the 5 identified significant risk factors

Table 2: Ranking of extent of risk occurrence/ impact and degree of risk

Risk factors	Rank	Overall risk extent mean	Overall risk impact mean	Overall degree of risk
Variations by the client	1	3.26	3.05	9.93
Change in design by client	2	3.16	2.98	9.41
Change in scope of works	3	2.74	2.86	7.84
Unexpected site conditions	4	2.21	2.26	4.99
Change in design by Architect	5	2.09	1.95	4.08
Problems arising due to client's lack of experience	6	2.07	1.91	3.95
Inadequate specification	7	2.05	1.77	3.62
Extremely competitive tender	8	1.98	1.70	3.36
Third party delays	9	1.93	1.67	3.23
Defects in design	10	1.86	1.65	3.07
Delay in resolving disputes	11	1.79	1.65	2.96
Delay in nominated/ named material supplier	12	1.72	1.60	2.76
Underestimation of quantities	13	1.65	1.49	2.46
Local concerns and requirements	14	1.51	1.47	2.21
Contract document conflicts	15	1.40	1.42	1.99
Project funding problems	16	1.35	1.37	1.85
Ambiguous contract terms	17	1.28	1.26	1.61
Loss or damage by fire or flood	18	1.07	1.05	1.12

Table 3: Multiple linear regression coefficients of significant risk factors

Risk variables	Variation
(Constant)	-0.047
Variation by the client	0.042
Change in design by client	-0.035
Change in scope of works	-0.006
Unexpected site conditions	0.029
Change in design by Architect	-0.029

Table 4 also shows the accuracy of the developed model. The coefficient of multiple correlation R which measures the correlation between the variables shows a fairly good correlation. However, the R squared (41.2%) and the adjusted R squared (7.8%)

which measure the predictive power of the model are not too promising. However, the model provides an indication that relationships exist between the variables but may not be a strictly linear relationship.

Table 4: Accuracy measurement of regression models

Measure	% Variation
R Squared	0.412
Adjusted. R Squared	0.078
Coefficient of multiple correlation R	0.642

In order to test the predictive ability of the model, 7 new cases were used for validation. Table 5 shows the validation results. The result shows a variation in prediction of between 3% and 33%. This is not unexpected due to the low measure of accuracy obtained from the R square and adjusted R squared.

Table 5: Modelling validation results

Project No.	Actual % Variation	Predicted Variation	% Absolute deviation
1	0.106	0.153	4.67
2	0.093	0.123	3.01
3	0.27	0.116	15.39
4	0.017	0.023	0.62
5	0.041	0.371	33.03
6	0.131	0.204	7.27
7	0.104	0.175	7.11

CONCLUSION

This study offers two main conclusions. First, within the limitation of the data collected, it is evident that the significant risk factors impacting the variability between tender sum and final account relate to the level of design information or lack of it at the pre construction stage. Those significant risk factors include 'changes in design', 'variations by the client', 'changes in scope of works' and 'unexpected site conditions'. This finding corroborates Winch's (2010) assertion that the more information is available at the pre construction stage, the less risk to contend with during construction.

Secondly, a predictive model was developed using the MLR method. The validation results from testing the developed model showed that the difference between the predicted variation and actual variation ranges between 3% and 33% suggesting that

the accuracy level of the model is not that promising. Despite the low level of predictive accuracy achieved by the model, the promising coefficient of multiple correlation provided an indication that a relationship exists between the dependent and independent variables which are strictly non linear. This therefore points to exploring other black box approaches to modelling.

QUALITY RISK MANAGEMENT IN COMPLEX CONSTRUCTION PROJECTS: A CASE STUDY

Prof. James Sommerville[1], Dr. Nigel Craig[2], Barbara Chomicka[3]

Glasgow Caledonian University, Cowcaddens Road, Glasgow G4 0BA, Scotland, UK

ABSTRACT

Risk management is a key project management stream which allows the project team achieve project objectives in terms of time, cost, quality, safety and environmental sustainability. There are various holistic approaches to risk identification, analysis and impact assessment and there is literature available on some aspects of construction risk management such as time or safety. However, the concept of quality risk has not attracted a similar scrutiny, as projects where quality is a dominant objective are rare and usually confidential. The robust quality management practices adopted on such schemes are too complex and expensive to be adopted in the wider construction industry; however, quality risk management processes which complement them can be applied in any construction project irrespectively of its budget and objective to drive positive change. Quality risk management processes implement quality awareness, facilitate a culture which encourages the ongoing identification and assessment of quality failures, allows the project team to assign ownership of management actions aimed at reducing the occurrence of quality failures and to align quality monitoring and reporting procedures with other project objectives' monitoring and reporting actions. This research investigates quality risk management processes implemented on a large project in the UK, from a project stakeholder perspective.

Keywords: quality management, quality risk management,

INTRODUCTION

Quality risk management revolves around management of a potential that a chosen action or activity will lead to an undesirable quality outcome (e.g., quality failure). The management of risks associated with quality involves all project management work streams and two project management work streams in particular: risk and design management. There are various holistic approaches to risk management (Zou, et al. 2009) and there is literature available on some aspects of construction risk management such as time or safety. Similarly, there is extensive literature available on quality management. However, the concept of quality risk has not attracted similar scrutiny, as projects where quality is a dominant objective are rare and usually confidential. The robust quality management practices adopted on such schemes are

[1] J.Sommerville@gcu.ac.uk
[2] Nigel.Craig@gcu.ac.uk
[3] bchomicka@gmail.com

too complex and expensive to be adopted in the wider construction industry; however, quality risk management processes which complement them can be applied in any construction project irrespectively of its budget and objective to drive positive change. Quality risk management processes facilitate quality awareness and brings about a culture which encourages the ongoing identification, assessment, and rectification of quality failures. They also allow the project team to assign ownership of risk management actions and align quality monitoring and reporting procedures with other project objectives' associated monitoring and reporting actions.

With the aid of a case study it was possible to isolate quality risk management processes, methods and tools on the live project. These measures were deployed to raise the bar in terms of quality expectations on this project, to ensure that: 1) there are no mistakes, 2) outputs support the delivery of the project vision, 3) outputs exceed expectations, 4) outputs are professional in their look, feel and content and, 5) outputs are the best that can possibly be delivered (ECH 2011). They have been developed on the project, where quality is the driving objective and where the design and delivery teams are 'committed to meeting the highest standards of quality in everything that they do' and 'everyone is responsible for ensuring that their work meets the highest standard of quality'(ECH 2011). The case study sets an example of how the project quality vision and mission can be translated into a robust quality risk management plan at all project levels, allowing for: 1) robust levels of granularity, 2) maintenance of ownership collectively and individually, 3) provision of assurance that assets are safe, reliable, meet design requirements and are fit for purpose, 4) establishment of work streams and processes that are planned efficiently and effectively so that value is optimised and delivery is on time and on budget, and 5) implementation of lessons learnt following any instances where an outcome does not meet expectation.

It has to be noted, that a project selected as a case study for this research aspires to become an exemplar for how major, complex, high profile projects should be led, managed and delivered (ECH 2011).

RESEARCH METHODOLOGY

The following research methods: 1) literature review, 2) review of earlier research which included three case studies and 3) specific case study analysis, have been selected for this study. In line with this approach, there are three phases in this study: 1) investigation of existing research into quality risk management, 2) review of research (unpublished) on drivers and cost implication of quality failures in the construction industry undertaken by the researchers at Glasgow Caledonian University and 3) exploration and interpretation of the specific case study. A literature review was chosen as a staring point of this research to establish subject background, learn from other research, formulate research problems, synthesise the work of others, and compare with other research strategies (Ridley 2008). However, due to the limited availability of research in the field of quality risk management, relevant aspects of risk and design management research were reviewed. In phase two, the findings of the earlier research involving case studies was used to compare and validate approach and facilitate analysis of findings. In phase three, the findings of the earlier phases were used to analyse the case study selected to best illustrate the quality risk management practices. The case study is a live, confidential, prestigious, £4bn mix-use scheme in

 ISBN: 978-1-84219-840-7 .

the South of England. The first phase of the project is currently at RIBA Stage C+, and remaining three at RIBA Stage B. The basis of the case study review formed project's Programme Execution Plan (PgEP) and relevant Project Execution Plan (PEP) and discussions with client representatives and project managers responsible for the project set up.

QUALITY RISK MANAGEMENT – CASE STUDY

There is a variety of quality and risk management definitions, methods and initiatives utilised in the construction industry. For this reason, the review of the quality risk commences with the baseline definitions of these terms in the researched case studies (as set out in the Programme and Project Execution Plans).

Definition of risk

Risk is the potential that a chosen action, activity or inaction will lead to an undesirable outcome (Ratliff and Hanks 1993) – a chance of, or a situation involving such a possibility. Risk management is at the heart of construction project management and revolves around the process of identification, assessment, and prioritisation of risks (ECH 2011). It is an important part of the decision-making process of all construction companies (Mills 2001) and a key project management work stream which allows to achieve project objectives in terms of time, cost, quality, safety and environmental sustainability (ECH 2011). Risk management is linked to other project controls, such as quality management, change management, schedule management or cost management. Therefore, to effectively manage project risks, all project controls have to be set up in conjunction with the risk management methodology. In the researched case study there were a total of sixteen parallel project controls and work streams, which were carefully integrated to ensure that all processes are aligned to allow their effective operation.

Definition of quality

The baseline definition of quality adopted in the case study has been described as 'a delivery of a product of the highest standard of quality and to exceed client expectations' (ECH 2011). The effective management of risk associated with such high quality requirements necessitated adoption of a very specific approach to quality: a performance-based quality system. There are two distinct approaches to quality management utilised in the wider construction industry: certification and performance-based, both of which operate on both organisational and project level. In the first, certification-based approach, a client (or client's representative) selects the project team among the firms with the relevant ISO certification, accreditation or quality kite mark to ensure that all parties involved in the project are committed to following an established quality methodology. In this approach firms manage quality within their own remit and the outcome is a product which is perceived as a sum of it parts, which is then reviewed at the end of the process to ensure it conforms to the required quality standard. In the performance-based approach, there is a continuous joint review of the team effort to improve the performance of the project. In line with this approach, everyone is responsible for ensuring that the outcome of the joint effort meets the required standard of quality. Both approaches are utilised in the construction industry, with the certification-based approach prevailing on the smaller, low end projects and performance-based systems on larger and more prestigious schemes.

 ISBN: 978-1-84219-840-7 .

QUALITY RISK MANAGEMENT PROCESSES

In the case study, the quality risk management started at the project conception, when client's brief was developed. The client specified the relative importance of quality in relation to other main project goals -- as the main objective -- which has then been incorporated into the client brief. All relevant identified risks were captured in the bespoke risk management structure, which consists of three levels: programme, project (phase) and suppliers and contractors. This structure allows to record quality risks at the appropriate level where they will be best managed. Within this structure, all risks are further divided into three groups: threats (defined as uncertain events in the future that, if realised, will have a negative effect on project's quality objectives), opportunities (defined as uncertain events in the future that, if realised, will have a positive effect on project's quality objectives) and issues (defined as certain events that, when they occur, will have an effect on the achievement of project's quality objectives). All identified quality threats, opportunities and issues are dealt with as three separate processes following the same principles, approach and methodology.

The established risk management process consists of the following five steps: 1) risk identification, 2) risk analysis and evaluation, 3) risk action (transfer, acceptance, avoidance or mitigation), 4) risk monitoring and review and, 5) risk reporting. The key management tool in **quality risk identification** are risk registers, which contain the following information for each identified quality risk: 1) a full description of the quality risk, detailing its cause and the consequence should it occur, 2) a unique number identifying the risk, 3) qualitative risk score combining likelihood of occurrence and impact (usually combined cost and time), 4) quantification of risk (three-point estimate of risk cost), 5) action plans to manage the risk in terms of overall responsibility for managing the risk with a clear risk owner, 6) specific actions to be undertaken (including clear completion dates), 7) action owners responsible for delivering individual actions under the direction of the risk owner. The quality risks were identified with the aid of workshops, brainstorming and prompt lists. It is envisaged, that in line with the project progress, that the project management team will undertake also structured interviews with people who have relevant experience to contribute ideas and advice to contribute to the list. **Quality risk analysis and evaluation** - the 'scoring' of risks - is a vital component of quality risk management. The case study's risk register scores quality risks against both probability and impact. This allows to avoid instances where a significant amount of time is spent mitigating a quality risk when the likelihood of it occurring is negligible. Following this exercise each risk is then classed as 'Red', 'Amber' or 'Green'. **Quality risk action plans** were developed by risk owners. **Quality risk monitoring and review** is a regular and ongoing process, which involves periodic risk review meetings and risk workshops at agreed Gateways to ensure that the quality risk management procedure is being fully adhered to. The review includes: 1) technical review meetings, 2) operations and systems, 3) performance, 4) procurement, 5) supply and maintenance. **Quality risk reporting** involves: 1) risk mitigation reviews, 2) risk management meetings and 3) quantitative risk analysis. The quantitative risk analysis process will be utilised as the project progresses to quantify cost, time and performance risks on a consistent basis. In this exercise, a risk register will be quantified to create a distribution of possible outcomes and analysed using Oracle Primavera Risk Analysis software to identify the cumulative probability curve for the whole project. The process will involve

 ISBN: 978-1-84219-840-7 .

establishment of the project baseline, its cost-loading with the cost estimate and processing using a Monte Carlo stimulation.

QUALITY RISK MANAGEMENT TOOLS

In the researched case study, risk management tools included, for example, selection of the right team, project procurement strategy, project controls, establishment of processes of governance, establishment of relevant KPIs and KRIs, verification and validation processes, baseline alignment monitoring, interventions, soft landing initiatives and provision of samples, mock-ups and exemplary units. A selection of these processes is briefly described below.

Selection of the right team

During the competitive consultant procurement process only firms with excellent quality delivery track record were taken into consideration. The project team consists of hand-picked individuals with a proven experience and excellent references from previous clients. To further address the quality objective of the scheme, consultants' fee schedules and resource levels were negotiated, resulting in an equal fees split of between design and compliance (50/50) as opposed to the proportion of between 70 and 80 per cent of resources being allocated at the design stage and between 20 and 30 per cent at compliance monitoring, which is the prevailing design consultants split in the industry. It was also ensured, that the highest level of resource is committed to the project, resulting in director-level involvement often matching the one of assistants (as opposed to between 5 and 10 per cent prevailing in the industry).

KPIs and KRIs

Key Performance Indicators (KPIs) and Key Risk Indicators (KRIs) are commonly used to evaluate the progress of a particular activity in which a construction organisation is engaged. KPIs are a type of performance measurement (Beatham, et al. 2004) which defines a set of values used to measure against. KRIs is a measure used to indicate how risky an activity is. The difference between KPIs and KRIs is that KPIs is meant as a measure of how well something is being done while the KRIs is an indicator of the possibility of future adverse impact. KPI provides information on making progress toward strategic goals, and KRI allows the project team to identify potential event that may negatively affect continuity of the particular construction activity (or a whole project). Both indicators are reliant on understanding of client's strategic goals (i.e. what is important for the client) and depends on a project organisation. In the researched case study there are common indicators for all firms involved in the delivery, which were set by the project manager. On smaller projects there is rarely a 'centralised' KPIs and KRIs system, which results in every firm measuring their own performance in line with their own, bespoke set of standards, for example engineering firms have different internal KPIs than contractors involved in a delivery of the same project. This situation, due to inconsistency of approach, creates additional quality risks. In the researched case study, KPIs and KRIs included, among many other, number of industry awards, media coverage (positive and negative), environmental performance, continuous development of people and stakeholder and client feedback. An example of established stakeholder and client feedback KPI included a quarterly delivery team performance review (engagement scoring) survey employed to monitor and measure client's perception of service quality. The survey is based on the SERVQUAL method, which focuses on ten dimensions measured on a scale from 1 to 5, and is available online to all team members via surveymonkey.com.

Verification
Verification is a suite of processes, which allow the team members to check whether a product or service meets specifications and project objectives. It includes three parallel work streams: desktop study and paper trail, commissioning and inspections. In the case study, desktop study and paper trail includes many design checking processes such as brief tracking (process of monitoring of alignment of deliverables with the client brief) and traceability (process of recording all changes occurring throughout the development and linking them to the original client brief) processes. Commissioning, a multi-phase process that ensures that the interacting systems in a building are properly installed and operating (Akin, et al. 2004), due to the early design stage is concerned with whether the programme and design are delivering the client's desired functionality (whether they are compliant with specifications and client's brief). In the later stages, this performance verification tool will focus on: 1) Ensuring that the performance of the selected building equipment matches design specifications and delivers the intended functionality, 2) All installed building equipment is tested in an operational environment to validate the functionality of the solution and that 3) Training and familiarisation of the facilities management, maintenance contractor and end user representatives has been completed (Akin, et al. 2004). Inspections, which are 'field' reviews which aim to establish whether the finished works meet client brief and whether all components properly fit together, is scheduled to be carried out throughout the whole construction process and includes a structured final inspection regime to ensure that all defects identified during the construction process have been rectified and the finished works standard reflects approved benchmarks (set out in the approved samples, mock-ups and exemplary units).

Testing
There are various testing regimes utilised in the delivery of construction projects, which can be divided into three groups: regimes driven by legislation, regimes which are part of the building delivery and commissioning and additional, 'voluntary' ones. In the researched case study, the 'voluntary' testing regimes include, for example, additional (40 per cent) façade water hose testing in addition to the 'standard' 10 per cent of the façade area carried out as a building delivery testing.

Validation
Validation is a processed of acceptance of buildings' design and works. The design is validated (i.e., the compliance with the specifications and alignment with project objectives is confirmed) on the basis of the relevant design team report, client review, audit or designated person's (for example project or programme director's) judgement and interpretation of evidence. The need for the design validation stems from the fact that the design usually evolves throughout the delivery process which significantly increases the risk of quality failure.

Samples, mock ups and exemplary units
Samples, mock ups and exemplary units are construction best practice tool allowing the contractor to identify any buildability issues, identify opportunities for pre-fabrication, sequencing strategy, and to provide quality standard benchmark for subcontractors and suppliers to understand (and be measured against). Samples, which will be required in the researched case study include, for example, stone for the facade, grilles, wall panels, timber flooring internal stone or carpets. The examples of mock ups which will be required include floor and wall junctions, bulkhead details,

 ISBN: 978-1-84219-840-7 .

shadow gaps and doors (with ironmongery, frame and architraves). The examples of exemplary unit typologies include a full apartment (to understand spatial relationships, interfaces and performance and to reduce amount of rework). It is usually expected that all exemplary units and selected mock ups are fully functional, including, for example, working ventilation to test acoustics or water supply pressure.

The design team is expected to identify samples, mock ups and exemplary unit requirements early in the design process and there is a set, rigorous pre-contract and post-contract samples, mock ups and exemplary units sign off process in place.

Soft landing

There is also a provision for an initial 'shakedown' period identified by Brand (1984), which occurs when the end user moves in. At handover a building goes through a stage of a 'shock', in which the systems which were installed correctly, tested and certified occasionally malfunction and require adjusting in line with the end user specific 'manner' of building exploitation. The focus of soft landing is on handover and post occupation after care. Its purpose is to provide the structure for project teams to stay engaged after practical completion, assisting the client during the first months of operation to fine-tune and de-bug building's systems and to ensure that the occupiers understand how to control and best use their new work environment. It includes procedures and example checklists which act as signposts for design teams to help end-users get to grips with their unfamiliar and complex buildings and allows for a full programme of post-occupancy evaluation.

CONCLUSIONS

It is widely recognised in the construction industry that quality cannot be 'inspected into a project at the eleventh hour' but 'built into every stage of the process via the 'right first time approach and systematic checking process' (SRM 2011). To ensure that this process is implemented and robust, and that every outcome maintains the required standard of quality firms delivering large, prestigious construction schemes utilise a number of quality, design and risk management processes and tools. The robust design and quality management practices adopted on such schemes are too complex and expensive to be adopted in the wider construction industry, as the cost associated with the deployment of performance-based methods on the organisational and project level (appointment of more expensive firms, additional professional appointments, additional scope elements for consultants, deployment of expensive measures such as mock-ups and exemplary units, additional testing and inspection regimes, specific procurement methods) is significant. However, as found in this research, quality risk management processes which complement these expensive design and quality management provisions can be applied in any construction project irrespectively of its budget and objective to drive positive change.

It is hoped that the quality risk management approach discussed in this paper will contribute to the research in the field of design, quality and risk management and project controls set-up on construction projects, so engendering a culture of continuous improvement.

REINSTATEMENT OF FLOOD AFFECTED PROPERTIES: EXPERIENCES OF SMEs AFFECTED BY THE 2009 COCKERMOUTH FLOOD EVENT

Gayan Wedawatta[1], Bingunath Ingirige[2], David Proverbs[3]

[1,2] *Centre for Disaster Resilience, School of the Built Environment, University of Salford, UK*

[3] *Construction and Property Department, Faculty of Environment and Technology, University of the West of England, UK*

ABSTRACT

Recent policy changes in the UK encourage at-risk communities to learn to live with and adapt to flooding. Adaptation of individual properties by embracing resilient and resistant measures is an important aspect endorsed therein. Uptake of such protection measures by property owners, including that of Small and Medium-sized Enterprises (SMEs), has traditionally been low. A post-flood situation offers an opportunity to reinstate / reconstruct by integrating flood protection measures, in such a way that reduce damage and enhance the ability to recover in the event of a future flood incidence. In order to investigate the reinstatement / reconstruction experiences of flood affected SMEs, those affected by the 2009 Cockermouth flood event were studied. The results of a questionnaire survey revealed that many SMEs have opted for traditional reinstatement rather than resilient reinstatement. A detailed case study revealed requirements of getting the business back and running as soon as possible, a lack of guidance and advice from professionals and financial concerns as some of the barriers faced by SMEs. It is important that SMEs are provided with necessary guidance during the post-flood reinstatement stage, in order to make sure that the opportunity to build back better, integrating flood-protection measures is grasped by the SME owners. Stakeholders related to the construction industry, who are actively involved with post-flood reinstatement work, have an important role to play in this regard, providing necessary guidance and expertise to flooded SMEs.

Keywords: adaptation, flood, resilience, reinstatement, SMEs

INTRODUCTION

Flooding is a hazard that affects communities in the UK regularly. Flooding could occur in different forms, and the most commons forms in the UK include river, coastal, surface water, sewer, and groundwater flooding (Environment Agency, 2009a). Consequently, a considerable proportion of properties in the UK remain at risk of flooding. Figures published by the Environment Agency identified that about 5.2million properties in England; amounting to one in six, remains at risk of river,

[1] g.s.d.wedawatta@edu.salford.ac.uk
[2] m.j.b.ingirige@salford.ac.uk
[3] david.proverbs@uwe.ac.uk

coastal or surface water flooding (Environment Agency, 2009b). Acknowledging that it is not technically, economically or environmentally feasible to prevent flooding altogether (Defra, 2011), recent policy changes in the UK encourage at-risk communities to learn to live with and adapt to flooding. Accordingly, a greater emphasis is placed upon property-level flood protection. For example, the National flood and coastal erosion risk management strategy for England (Defra, 2011) that complements Flood and Water management Act 2010, declared that one of the ways that the government seek to reduce the threat of flooding as by "increasing public awareness of the risk that remains and engaging with people at risk to encourage them to take action to manage the risks that they face and to make their property more resilient" (Defra, 2011: 14). It further goes on to say that "householders and businesses at flood risk should take the appropriate steps to better protect their properties through property level resistance and resilience measures" (Defra, 2011: 26). A part of the responsibility of safeguarding against flooding is thus expected to be taken by at-risk communities; including households and businesses.

A post-flood situation offers a window of opportunity to integrate property-level flood protection measures to the existing building stock, by opting for flood resilient and resistant reinstatement. Wassell et al (2009) reported that property owners in areas at risk of flooding could benefit from resilient reinstatement following significant flood damage, given that it is more cost-effective to implement at that time. Further, previous studies have reported that flood affected property owners are likely to opt for such measures, than those without flood experience (Kreibich *et al.*, 2007; Harries, 2008). However, uptake of property-level protection measures is not without barriers. Lamond and Proverbs (2009) categorised such barriers in to four; financial, informational, emotional and timing constraints. If the issue of financial constraints is taken as an example, additional cost can be cited. Wassell et al (2009) calculated that the cost of resilient reinstatement of a domestic property could on average be 40% higher than that of traditional reinstatement. Similarly, Joseph et al. (2011) found that mean percentage additional resilient cost to be about 34% for residential properties flooded to depths of between 100mm - 1000mm during the 2009 flood event in Cockermouth.

Whilst previous work has dealt with post-flood reinstatement of households to a certain extent, studies focusing on the business sector; especially SMEs, is limited. This paper seeks to discuss findings of research work undertaken to investigate the uptake of property-level flood protection by SMEs during post-flood reinstatement of flood damaged property. The paper first presents the research method adopted, followed by findings of the research. Discussion of the findings lead to conclusions drawn and recommendations made subsequently.

RESEARCH METHOD

In order to investigate the reinstatement / reconstruction experiences of flood affected SMEs, those affected by the 2009 Cockermouth flood event were studied. Leading up to 2009 flooding in Cockermouth, approximately one month's worth of rainfall had fallen in the space of 24 hours and the impacts had been worsened by peaking flows in both the River Cocker and the River Derwent at similar times (Enviornment Agency, 2011a), leading to flood depths of over 1.5m in Cockermouth (Environment Agency, 2009c). Flooding in November 2009 had affected about 225 businesses directly (Cumbria County Council, 2010; Tickner, 2011). Although Cockermouth has experienced flooding before 2009 in the recent past; in 2003 and 2005 as well, the

 ISBN: 978-1-84219-840-7 .

event of year 2009 was seen as unprecedented due to the scale of its impact, and, therefore, provides a useful case study of repair and reinstatement of flood affected SMEs.

Information from SMEs was collected via a questionnaire survey as well as case studies. 48 SMEs were involved in the questionnaire survey, whereas 9 of them were studied further during the case study stage. Questionnaire survey reported a response rate of 25%, amounting to a reasonable response rate in comparison to previous studies of similar nature. SMEs studied were mostly micro sized businesses with less than 10 employees, going in line with the size-wise distribution of businesses in Cockermouth and the UK in general. Face-to-face interviews were conducted with the ownership, senior management of selected case study SMEs, in order to gather the required information.

FINDINGS

Post-flood reinstatement / flood protection

36 SMEs involved in the survey were directly flooded in November 2009, and hence required reinstatement work to be carried out to their business premises. Out of the flooded SMEs, half of the respondents had implemented at least one property-level flood protection measure to safeguard their business property in a future flood event. Measures such as reviewing property insurance, raising electrical sockets / wiring, and relocating vulnerable / important stocks / equipments to an upper floor were the most commonly implemented flood protection measures adopted by the SMEs (See Table 1). In half of the cases, SMEs had implemented 3 or more protection measures, suggesting that businesses who decide to enhance their flood protection are likely to choose a combination of such measures. However, uptake of property-level resistant measures such as flood barriers and resilient measures such as resilient flooring and wall finishes had been limited.

Table 1 – Flood protection measures implemented (Wedawatta *et al.*, 2012a)

Flood protection measure	As a % of businesses opting for flood protection
Reviewing property insurance	44%
Raising electrical sockets / wiring	33%
Relocating vulnerable important stocks / equipments to upper floor	28%
Obtaining property insurance	22%
Flood resilient flooring / floor finishes	22%
Obtaining temporary flood barrier(s)	22%
Conducting a flood risk assessment on property	22%
Storage of stocks / equipments above floor level	11%
Flood resilient wall finishes	11%
Remedial works to seal water entry points	11%
Other	28%

Resilient measures that attempt to minimise the impacts of flood waters on property, can be integrated to a property at the post-flood repair and reconstruction stage, by means of resilient reinstatement. During the reinstatement stage, SMEs had the alternative of either opting for like-for-like reinstatement to their flood damaged property, or opting for resilient reinstatement, thereby enhancing future flood protection. However, a comparison of the numbers of businesses opting between these

two types of reinstatement measures demonstrated that a majority had chosen like-for-like reinstatement. As shown in Table 2, 26 SMEs had said that they either repaired or replaced their wall finishes, but only 2 SMEs had opted for resilient wall finishes.

Table 2 – Comparison of like-for-like reinstatement and resilient reinstatement (Wedawatta *et al.*, 2012a)

Like-for-like reinstatement	Nr	Resilient reinstatement	Nr
Repairing / replacing wall finishes	26	Resilient wall finishes	2
Repairing / replacing floor finishes	24	Resilient flooring / floor finishes	4
Replacing doors	19	Flood proof external doors	0
Replacing windows	12	Flood proof windows	1

The difference observable could be partly due to SMEs lacking the relevant technical knowledge regarding the measures that had been implemented. Further, SMEs might not have known the exact work undertaken, as some had left the entire process in the hands of their insurance company or the building contractor. Considerable differences between the number of SMEs opting for resilient and like-for-like reinstatement suggest that the opportunity to build back better has not been embraced by many flooded SMEs and that much needs to be done to increase the uptake of resilient reinstatement.

Reasons for not opting for resilient reinstatement

When asked the reasons for not opting for flood protection measures, a major reason given by the SMEs surveyed was that it is the responsibility of the landlord to carry out property-level flood protection measures. This corresponds with the fact that nearly 60% of the survey sample were in rented and leased business premises, rather than in freehold property. Belief that flooding will not affect their property again in near future, reliance on insurance, and cost of protection measures were the other significant reasons cited by SMEs involved in the questionnaire survey. During the case study interviews, reasons for not opting for resilient reinstatement / property-level flood protection were further investigated. Issues mentioned by flooded SMEs are discussed below, under the categories identified by Lamond and Proverbs (2009). It has to be kept in mind that in addition to these categories, one of the key reasons mentioned by SMEs was the inability of SMEs in rented and leased properties to undertake resilient reinstatement and flood protection, as mentioned above.

Cost of property-level flood resilience and resistance measures and lack of financial incentive in terms of cost of insurance despite implementing such measures were two financial concerns often mentioned by SMEs. A SME director responding on resilient reinstatement commented that “the cost is prohibitive. No sign of the insurance companies’ policies being reduced by them”. As discussed earlier, resilient reinstatement is likely to be costly than normal reinstatement, although the benefits may outweigh costs if the risk of flooding is significant. For example, the Environment Agency (Thurston *et al.*, 2008) calculated that property-level flood resistance measures are economically beneficial for a business if the risk of flooding is greater than 4% (twenty five-year return period), whereas property-level resilience measures are beneficial if the risk of flooding is greater than 10% (ten-year return period). Further, Douglas et al. (2010) reported that flooded property owners implementing resilient reinstatement and additional flood protection measures are negatively affected by non-betterment clauses and inactivity of insurers. Inactivity of insurers, in terms of not providing an incentive for uptake of resilient reinstatement as well as not promoting the uptake of such measures, was noted in this research. For an

example, insurance may incentivise flooded SMEs either by keeping their cost of insurance at pre-flood values or even below, if resilient reinstatement is undertaken. It was found that flooded SMEs had experienced higher cost of insurance and higher excesses after the 2009 event (Wedawatta *et al.*, 2012b). This has been the same for the case study SMEs who had opted for resilient reinstatement measures as well. This suggests the proactive role that has to be played by the insurance industry, in increasing the uptake of flood protection by SMEs. It was also noted that much of the grant schemes made available to promote flood protection of properties were limited for households, and excluded business establishments. A micro-sized SME owner mentioned that his application for a grant to install flood barriers was not approved, as that particular scheme excluded business properties. It was suggested that such grants should also be available for small businesses, so that they can be better prepared for the future.

Informational barriers cited included lack of as well as in certain cases overloading of information on property-level flood protection. Case studies with SMEs revealed that some SMEs whose premises were significantly damaged by flooding, and thus required extensive reinstatement, had not received adequate guidance on flood protection. For an example, a SME who had overseen reinstatement works of its property by the business itself commented that it was not made aware of possible resilient reinstatement measures and that it was not sure whom to approach for this advice. Conversely, it was also noted by some SMEs that there were many commercial businesses; contractors, suppliers, professional advisers, etc, marketing their products and services during the aftermath, adding to the confusion among flooded SMEs as to what to be done. Excessive marketing activities of such commercial organisations had also forced some SMEs to completely ignore such approaches. This might have contributed to valid information not being received by SMEs even through reliable sources, due to flooded SMEs getting used to ignore such approaches. It was mentioned that, although the advice was available if it was looked for, selecting between the sources was a problem for flooded small businesses. These concerns were echoed in a Defra consultation (Defra, 2008) which found that whilst it was difficult for individual property owners to select flood protection measures with confidence unless they have expert advice, such advice is likely to be treated with suspicion if comes from a source promoting a particular product. Therefore, the need for independent expert advice was highlighted. The case study findings suggest that there is scope for improvement in flood reinstatement and protection advice provided to SMEs. For example, one SME owner stated that some of the plastering collapsed due to improper drying techniques adopted. SMEs pointed out several situations where SMEs were provided with incorrect advice by building contractors and consultants employed, without considering the nature of buildings, existing construction methods, and regulations concerning listed buildings. Therefore, there seems to be a role for a reputable organisation like the Environment Agency, and professional associations like the RICS to step in, and provide technical expertise through its membership.

Emotional barriers elicited from comments of SMEs included perceptions that flooding will not affect their property again in near future, property will be flooded even with property-level protection, and that the responsibility of ensuring protection lies with the national and local government bodies. Some SMEs viewed that flooding of 2009 as unprecedented, and an event of similar scale will not occur in the near future. As Lamond and Proverbs (2009) discussed, ownership of the problem of

flooding is also highly emotional. SMEs viewed that it was the responsibility of the national and local governments to provide protection against the risk of flooding, particularly through community-level structural flood protection and regular river maintenance. It was noted by SMEs that regular maintenance of the rivers Derwent and Cocker in Cockermouth has to be carried out to minimise the risk of flooding. It was mentioned that dredging, which once used to be about once a year, was later changed to once every three years, and latterly river dredging has not been done for years. This was identified as an important step towards minimising future flood risk, rather than measures at the individual level. A new £4.4 million flood alleviation scheme for Cockermouth is now in progress to reduce annual risk of flooding to 1% (Enviornment Agency, 2011a). Further, the Environment Agency claimed that the river channels are surveyed annually to determine the level of maintenance work required, as part of its risk based approach for the removal of gravel in areas where the risk of river flooding is high (Enviornment Agency, 2011b). For some SMEs, strain of having to manage reinstatement of both their home and business was an issue. SMEs viewed the trouble and efforts of having to recover from another flood event in the near future might be too much for some of the businesses, who had already undergone the stress of a major flood event.

A common timing constraint cited was the priority of SMEs at the time to start their business back as soon as possible, after completing reinstatement work swiftly. Loss of business activities for a considerable period of time is particularly damaging for SMEs, whose only income may be lost during that period, and thus the priority had been to reinstate flooded property as soon as possible. This has discouraged SMEs to consider lengthy negotiations with insurers, planning authorities etc. It was mentioned by the SMEs that there were significant delays due to different parties insisting on their way of working, rather than coming to consensus and progressing with the work. Hence it was suggested that there has to be communication and co-operation between different parties involved in planning, obtaining approval and carrying out refurbishment activities, especially as many of the flooded buildings were listed historic buildings.

CONCLUSIONS

Previous research has revealed that resilient reinstatement is more costly than that of like-to-like reinstatement of flooded properties. However, benefits of flood protection to properties are likely to outweigh costs for properties in areas of higher flood risk. Benefits may be higher for SMEs, considering the stocks and equipments of a business, and factors including loss of income and potential for loosing customer base during the time a business is closed after flooding. Therefore, although the cost is high, given the significant increases in excess of property insurance and level of flood risk in Cockermouth, resilient reinstatement could well be beneficial for SMEs in the long run. Although the 2009 flood event provided a good opportunity to build back better for flooded SMEs, this opportunity does not seem to have been grasped by a majority of SMEs affected.

Over half of the SMEs surveyed were in rented or leased business property, and this was cited as a major reason restricting the ability of individual SMEs to safeguard their property via property-level flood protection measures. In this regard, further interventions seem needed to encourage landlords to make adaptation interventions, to their rented properties. SME owners, especially micro business owners, are further restricted by the fact that grants and financial assistance provided to adapt properties

to flooding are often limited to households. It is important that such financial assistance is made available to SMEs, especially to smaller businesses that are often restricted by financial constraints.

Dependence of SMEs on their insurance policies to recover following a flood event is well known. Insurance companies are therefore significantly involved in reinstatement activities, either directly or indirectly. As a result, insurance could be an effective source of promoting property-level adaptation during this stage. Such activities could be further encouraged by insurance companies, via initiatives such as lower insurance premiums and reduced excesses. However, non-betterment clauses in insurance policies and the free market situation where policy owners are able to switch their insurance company seem to discourage insurance companies to be actively promoting flood adaptation among their flooded policy holders during reinstatement. There seems to be the scope for a government led initiative to facilitate adaptation of flooded properties either via insurance companies by incentivising them for the additional investment or by making grants available to individual SMEs.

For most SMEs; especially to SMEs with a single business premises, restoration is vital for the successful continuance of the business in the aftermath of a flood event. Therefore the priority of SME owners at the time has been to restore their business premises as soon as possible, rather than to explore opportunities to build back better or to invest time and efforts to investigate ways and means of adapting their business premises to sustain a future flood event. In this regard, it is important that SME owners are provided with necessary guidance and advice in a timely manner following a flood event.

Some SMEs whose premises were significantly damaged by flooding, and thus required extensive reinstatement, had not received adequate guidance on flood protection. Post-flood advice and guidance often seem to focus on households, limiting the ability of SMEs to receive information specific to businesses. It is important that SMEs are provided with proper guidance at this stage, and directed towards the necessary professional advice if required. The role of local councils and local business networks is vital in this regard, who have a direct relationship with SMEs. Further, stakeholders related to the construction industry, who are actively involved with post-flood reinstatement work, have an important role to play in this regard. It has to be ensured that SMEs are provided with accurate guidance and professional advice, at a time where they are likely to be subjected to a high degree of trauma and stress and are forced to engage in reconstruction activities that they are not familiar with.

Recent changes in national policy encourage communities to adapt to flooding and be resilient, by opting for property-level protection measures. Although widely advocated, costs and perceived benefits of such measures are seen as a barrier for their uptake. Higher costs of insurance and excessive excesses could mean property-level protection is more beneficial for at-risk SMEs. Further research in this regard is needed, in order to assess this phenomenon and develop the knowledge base on benefits of property-level adaptation to at-risk SMEs. These issues are likely to affect cost / benefit of resilient reinstatement and property-level flood protection for SMEs. Factors that motivate SMEs to implement resilient reinstatement is worthy of further investigation and further research in these areas is recommended.

ACKNOWLEDGEMENT

The research was funded by a grant received from the Royal Institution of Chartered Surveyors (RICS) Education Trust. Assistance received from Dr. Les Tickner, Cockermouth Town Centre Flood Recovery Co-ordinator, Allerdale Borough Council, in conducting the Cockermouth study is also acknowledged.

"HOUSING FOR ALL" DEVELOPMENT PROJECTS BY THE GOVERNMENT AS A TOOL FOR CREATING EMPLOYMENT

ABSTRACT

The purpose of this study was to highlight the lack of labour- intensive construction methods that are used on low-cost housing projects sponsored by the South African government. Using observations, interviews and questionnaires this research was conducted on as a case study in a development area called Tshepiso Township, South of Johannesburg. This research has proven that with the labour-intensive method it is possible to work on low-cost houses using a minimum budget. The community will get skills and employment leading to housing for all. Employment creation in the construction industry is also sustainable. Due to high urban migration, housing, unemployment and services have become a major source of protests in the cities, because of shortages. This study was limited to the Construction industry activities in the province of Gauteng in the city of Johannesburg. It is recommended that all interested contractors would be required to design a labour-intensive work programme before tenders are awarded and commencement of the project.

Keywords: employment creation, labour intensive, low-cost housing,, poverty alleviation, public funding and squatter camps.

INTRODUCTION

This research was seeking to find ways of alleviating unemployment through labour intensive construction methods on government funded housing development projects in South Africa. The study was making a follow up on the strengths and weaknesses of the current contribution of the construction industry towards the economic development through the infrastructural development. This development runs into excess of over billions of rands every year in the annual budget of the government meant to provide houses for all.

[4] sulimanazhar@gmail.com

According to the South African constitution 1996;108, "Everyone has the right to adequate housing; the state must take responsible legislative and other measures 's within its available resources, to a the progressive realization of this right" With this task in mind the government according to Wohlmuth (1997) a programme entitled Reconstruction and Development Programme (RDP) was launched through the department of Human Settlement in collaboration with the department of National Housing to address the housing shortage in the country.

Background

In 2000 Irene Grootboom a South African housing rights activist who had been left homeless after an eviction from an informal settlement took the government to court demanding their right to housing.

According to researches that were conducted by Evans 2001, Eds Kook and Gelderblom 2003; p266, and Leckie 1990 the courts did pass the verdict that section 26 guarantees the right to have adequate housing it also guarantees every child's right to basic shelter. It therefore led to a decision that the people could not be evicted unless the government had provided alternative housing which meets the expected basic standards. These houses would enable the people to vote, as one would need to have a recognized address in order to carry out this right. However Leckie (1990) went on to say that housing rights did not mean that the government has to build houses for the entire population and it especially does not mean that houses would be provided free of charge.

The level of unemployment which leads to poverty is very high in the whole country. Previously the construction industry through the Bantu Building Workers act of 1951 had legalized the training of blacks in the construction industry but limited the places they could work. According to the Countrystudies.us (1994) approximately 87.4% of the 40 400 000.00 South African citizens were not gainfully employed. MacMillan (2004) defines unemployment as a situation where people who are able to work are unemployed.

Stats Sa (2011) calculates the unemployment rate as the proportion of the labour force that was not employed and the labour force comprises of all the persons who are employed plus the unemployed. The unemployed rate for South Africa in the first quarter of 2011 was 25%. Gauteng Province (One of the 9 provinces in country were this study was conducted) had an unemployment rate of 26.9% which was higher than both the national unemployment rate. Other provinces with similar economic activities such as Kwa Zulu Natal and the Western Cape had lower unemployment rates of 20.3% and 22.2% respectively. Bendix (2001) blames this on the lack of labour based construction methods in the industry as it contributes to the loss of jobs without creating any.

According to Stats Sa (2010) the construction industry lost 45 000 jobs from the third quarter of 2010 to the first quarter of 2011. More specifically Gauteng as during this same period it recorded a loss of 24 000 jobs in the construction industry alone. Labour-intensive as defined by Founters (2006) is "the use of both machinery in the process but predominantly labour, without compromising the quality of the end product." McCutcheon (1995; p 332) defines it as "the effective substitution of equipment for labour" and this results in job creation in the industry. Further on McCutcheon (2003: p 151) writes that labour-intensive methods of construction does aim at achieving a significant (300 to 700 percent) increase in employment in comparison to machine intensive methods.

A comparison between Labour-Intensive and Equipment-Intensive construction methods

Labour-intensive methods of work will increase employment by percentages ranging from 300% to 600 % Thwala,(2006). According to Fountas (2006), the construction industry creates a large amount of employment, and specifically states that the use of labour intensive construction methods will increase employment. The adoption of labour-intensive construction methods for local projects ensures that finances remain within the country as opposed to money leaving the country in cases where equipment-intensive methods are prevalent, thereby increasing South Africa's GDP (Fountas:2006).Today labour-intensive construction methods can compete with equipment-intensive methods both technically and financially with a good productivity if managed correctly (Ntja,1999). One can ensure strong productivity and outcomes in labour-intensive methods by ensuring that good management is present on site (Ntja, 1990).

In developed countries machinery is easily available where labour is in short supply and expensive, in contrast to developing countries, such as South Africa, where labour is abundant and machinery is scarce and expensive (Ntja,1999). With similar cost and time frames, labour-intensive construction methods could potentially produce the exact same quality as equipment-intensive construction methods would, and in some cases, even better quality (Fitchett, 2009). Fitchett (2009), also suggest that the predominant use of labour-intensive construction methods could generate up to seven times more employment than a predominantly equipment-intensive project, without jeopardizing the budget. According to McCutcheon (2008), "for labour-intensive work to be successful and a better option compared to equipment-intensive work the following need to be achieved **(**McCutcheon, 2008):

- *The construction project needs to be treated as a proper engineering project, and careful consideration needs to be given to the social and economic factors of employment*
- *The labourers must be able to perform the tasks without harming themselves*
- *A detailed technical analysis of the project must be performed*
- *The specification, design and tender procedure must be appropriate*
- *Labour used for the project should be productive labour*
- *Work should be allocated individually to the different labourers for their different tasks*
- *Planning and preparation for the project should be done for the optimal sequence of operations, various activities for each operation and which individual group of labourers will perform these acts. Team balancing of the entire project must be incorporated.*
- *Employment contracts should be appropriate and, employees should only pay for work done.*
- *Employers/labourers should arrange their own transport*
- *The appropriate tools for specific operations should be used carefully and maintained*
- *Site supervisors must be well trained and qualified to hands on advice and training to the labourers*
- *Labourers must be open to orders from the site supervisors and there must be a good relationship between the site supervisor and labourers of the specific projects.*

- *There must be a link between the local community and the site work*
- *The site needs to be organized*.

Design Framework

In this research, one sample site was analysed. The main criteria that were looked at when choosing a sample was as follows:

- The site had to be government subsidized or funded low-cost housing development
- The site had to be located in the Gauteng area
- The site had to incorporate elements of labour-intensive and equipment-intensive construction.

In this study a High-Density location Tshepiso low-cost housing development was used as a case study. The Global Housing Foundation, (2010) defined adequate housing as that which satisfies the need for basic services; such as water supply, drainage and electricity as well as sufficient security, privacy and environmental quality . The Department of Human Settlement has implemented the RDP housing programme in this area. The houses are approximately 40square metres; it consists of 2 bedrooms, a separate bathroom, a kitchen and a lounge.

With this development which is wholly funded by the government employment creation would applied in order to address poverty in the community to build the sand houses and impart skills to the labourers. The Construction Industrial development Board (CIDB) 2011 reported that according to the National Housing Forum 1994 employment opportunities in the construction of housing and infrastructure are dependent on the construction methods employed. Therefore in a developing country like South Africa where unemployment is rife labour-intensive construction methods would contribute positively towards the economy better that the equipment –intensive method of construction.

The population in Tshepiso was identified as relevant to this research as it was still at its developmental stage. An observation approach was used initially to collect the basic information on the availability of the facts and details for this study. Still using the qualitative research method instruments were designed in the form of questioners and interview schedules. These where meant to understand the workings of the area through the data collected. The interviews did target the contractors and government officials in various responsible offices of the Department of Human Settlement and Public Housing. Most of the questioners where designed for the labourers to give their input on their understanding of labour- intensive versus machine-intensive and how these can be implemented. It was ascertained that most of the contractors hired most of their labourers from the surrounding areas and communities, these where mostly from the nearby Soweto Townships.

DISCUSSION AND FINDINGS

The Tshepiso low-cost housing development is a project subsidised by the South African government. It is situated in the Emfuleni municipality, more specifically Tshepiso North Extension 4, on Boy Louw Street. The project surroundings are inclusive of both industrial and residential elements. The project commenced the initial phase of construction in March 2011. During the conduction of this research a total of 1000 housing units had been built. However 3500 housing units were due to be built. The initial phase of the Tshepiso North Extension 4 housing development construction is due for completion in December 2011.

 ISBN: 978-1-84219-840-7 .

The type of labour employed varied largely, in that, both women and men of all ages were given work opportunities, and the ages of labour ranged widely as well. The population consisted of 500 individuals, as this was the number of labourers employed on the entire site. From the 500 labourers, 7% were selected as respondents to the questionnaires designed specifically for the labourers on the sample site. In the context of this research, labourers were defined as targeted labour (McCutcheon, 1989). According to McCutcheon (1989), targeted labour can be defined as labour that is hired locally. The labourers were broken down into drivers, general and skilled labour. A total of 35 questionnaires were handed out to respondents on site, of which only 29 were useable, the remaining 6 questionnaires were not completely filled out and therefore considered "spoiled". Questionnaires were handed out with the help of the health and safety inspector to labourers working in excavations, concrete, masonry work, plastering, beam filling, bag washing and roofing. The following area by area observations were recorded.

Site clearance
Labour was employed as an alternative to machinery, compaction of the soil would take up to 15 times longer however, it would not be of the same standard. Also replacing one skilled labourer with one general labour does not create more employment.

Excavations
Both labour and machinery were used for excavation of the trenches. The total cost of each trench to be dug was R200, took one hour using a ditch- witch and employed three labourers. A ditch witch can be replaced by labour. The analysis regarding labour as an alternative to machinery in terms of time and cost feasibility will be done using information gathered from the data collected as well as the literature.

Concrete
It was established that ready-mix concrete was used. The cost of the ready-mix inclusive of delivery was R1200.00/.Four labourers were employed. One skilled labourer to assist in pouring the concrete as well as to supervise the pouring, two general labourers to assist in placing the concrete and one skilled labourer to compact the concrete with a poker vibrator. However, replacing ready-mix concrete with hand-mixed concrete may potentially provide additional labour. The analysis regarding labour as an alternative to machinery for mixing concrete in terms of time and cost feasibility will be done using information gathered from the data collected as well as the literature.

Brickwork
Brickwork utilised only labour.2 general labourers and 2 skilled labourers were employed for bricklaying. No machinery was implemented in this part of construction, and therefore an analysis to employ more labour will not be carried out.

Beam filling, Plastering and Bag wash
For beam filling, plastering and bag washing only labour was used. From informal interviews and observation it was gathered that no additional labour could be employed.

Finishes: removal of rubble/clearing of site

 ISBN: 978-1-84219-840-7 .

The removal of the rubble on site employed only machinery, for which one driver was required. From informal interviews with the contractor, it was gathered that additional labour could be employed by replacing machinery with labour. From the informal interviews the contractor stated that if only labour were to be used, two general labourers would have to make approximately 12 round trips per unit using wheel barrows to remove the rubble. Each round trip would take approximately 5minutes.

Questionnaire Responses

The number of personal questionnaires handed out depended largely on the willingness of the labourers to participate. Certain individuals opted out of being a part of this research because they were not South African citizens, and were afraid of deportation. All in all a number of 35 personal questionnaires were handed out to respondents on the Tshepiso Sample site. However, only 29 of the 35 personal questionnaires could be used, as the remaining 6 were "spoiled", as they were incomplete. There was therefore a response rate of 83%, which is regarded as an excellent rate of response. To overcome the language barrier, the health and safety professional assisted in translating and interpreting questions to respondents who experienced problems while answering the personal questionnaires. To assist in analysing the quantitative data obtained from the personal questionnaires pie charts will be used. A pie chart is an effective way to analyse quantitative data (Kent, 2001).

Data Analysis

The pie chart is a useful method in comparing categorical data with up to five different categories (Peck, Olsen, Devore, 2008). A pie chart takes the form of a circle, which is cut into 'slices', each representing a certain category (Peck et. al., 2008). According to Kent (2001), a pie chart, as opposed to a bar chart, for the analysis of data is effective as it clearly shows that the sum of all the slices adds up to 100%. Pie charts, for the analysis of research data are also aesthetically pleasing (Kent, 2001). This is the method that was adopted for this study to give a true summary on responses to each question.

CONCLUSION AND RECOMMENDATIONS

This research has shown that there is room for further employment in government housing developments. In light of the three areas of the construction process of the specific development which implemented elements of equipment-intensive construction namely; earthworks, concrete and the clearing of the site , it was found that it is indeed possible to employ more manpower, thereby employing the element of labour-intensive construction, which in turn would create further employment in the construction industry.

To further break it down, in earthworks, abolishing equipment-intensive methods completely for labour-intensive methods, would require three more labourers at a cost which was R88.40/unit less than when equipment was utilised. The use of labour over equipment in this area of construction would mean that the process of excavations per unit would only take twenty minutes longer. With a relatively good decrease in cost and minute increase in duration it would be feasible to replace equipment with labour, thereby creating jobs for three more labourers per unit.

In placing and mixing the concrete, it was found that replacing machinery with labour completely would create work for 12 labourers, which is 8 more than with ready-mixed concrete. Employing a hundred percent labour-intensive methods would cost only R357.09/unit less than equipment-intensive methods. The use of labour-intensive methods in placing and mixing the concrete would take approximately 26 times longer than with equipment-intensive methods. Employment however, would be created work for eight more labourers per unit.

In the clearing of the site, it was found that the implementation of labour-intensive methods of construction over and above equipment-intensive construction would employ two labourers, which is one more than with the use of equipment. In terms of cost, using labour over machinery would only cost R8.68/unit more than with machinery. In terms of duration, clearing the site using labour-intensive methods will take 15 minutes/unit longer than with equipment-intensive methods. Employment however, will be created for one more labourer per unit. Therefore, since 3500 units are intended to be built on the Tshepiso sample site, the 12 jobs created per unit will increase employment significantly. Even though cost decreases were diminutive in terms of earthworks and concrete, it must be noted that in the construction industry even the smallest of costs can make a difference. In the clearing of rubble employing additional labour-intensive construction did in fact prove an increase in costs by a small fraction. However it must be stressed that feasibility in terms of time was not a primary consideration of this research. The replacement of equipment-intensive construction method with labour-intensive construction resulted in longer durations in carrying out the three areas of analysis. Time however, was also not a primary consideration of this research.

The primary aim of this research was to identify the areas of the construction process of a low-cost housing government development where additional labour-intensive methods of construction could be implemented so that employment could be created, which in turn would assist in decreasing the national unemployment rate. As a result of this research it was found that there is room for the further implementation of labour-intensive construction methods on government funded or subsidised low-cost housing developments, which would ideally result in employment creation.

ABSTRACT

The office sector was responsible for 9% of the final energy consumption in the UK in 2011, however previous research has indicated that this sector has been slow to adopt energy efficient office features. This indicates that this sector presents significant opportunities for improvement. The Guinness Partnership has embarked on a two-year Knowledge Transfer Project (KTP) worth in total £125,372, that involves eco retro-fitting its offices to reduce the carbon footprint of its building portfolio and produce financial benefits. For the year of 2011, total gas consumption for its offices was 1,230,776 kWh and total electricity consumption was 3,192,206 with total CO_2 emissions of 1,963,023 kg. External benchmarking of the office stock using CIBSE 2008 data, highlighted that between 62-63% of its stock consumed more energy in comparison to their bench marks. Four offices were selected to carry out phase one retrofit. Post occupancy evaluation carried out on these offices concluded that that thermal comfort was an issue at certain times of the day and that. that occupants felt that they had a lack of control over their thermal comfort and lighting levels.

Keywords: Carbon emissions, energy audit, energy benchmarking, office buildings, post occupancy evaluation.

INTRODUCTION

The Guinness Partnership is one of the largest housing and care organisations in the country, owning and managing over 60,000 homes throughout England providing quality housing for people on low incomes. As part of their sustainability strategy, the charity wished to achieve a step-change in the carbon footprint of their property portfolio, reducing the demand for heat and electricity through energy efficient improvements to homes and estates. A two-year Knowledge Transfer Project (KTP) worth in total £125,372, commenced in November 2011 and initially involves eco retro-fitting Guinness offices to deliver environmental and financial benefits.

[1] jrg3@brighton.ac.uk
[2] adam.masters@guinness.org.uk

 ISBN: 978-1-84219-840-7 .

However, the long term goal of the project is to develop an eco-retrofit capability, which can be rolled out to the Partnership's residential homes.

The energy consumption of the service sector in the UK for 2010 was 18,357 thousand tonnes of oil equivalent, which accounted for 12% of the final energy consumption. Commercial offices were responsible for 9% of this figure (National Statistics 2011). This highlights that offices, which make up a proportion of the service sector are a significant user of energy and emitter of CO_2 emissions. It has been argued that a lot of the energy efficiency programmes have been aimed at the domestic and industrial sector leaving office buildings overlooked (Scrase 2000). However, the energy use statistics indicate that considerable improvement has been made in the reduction of energy use in the services sector. During the period of 1990 to 2009 there was a drop in energy consumption in the service sector of 1.1 million tonnes of oil equivalent, however in real terms if energy efficiency had remained at the 1990 level this figure should have been 67% higher, therefore the reduction represents a significant improvement in energy consumption in this sector (National Statistics 2011). Despite this improvement, there has still been a slow uptake of energy efficient office features (Pellergrini-Masini and Leishman 2011), this may be linked to the fact that for many companies energy cost only presents a small proportion of the total business costs and so is overlooked or seen as a not a priority (Wade, et al. 2003). Consequently this sector still offers significant opportunity for energy savings and proposing energy efficiency intervention measures can be less complex compared to other sub sections of the service sector such as warehouses or retail, due to the energy consumption pattern in office buildings, which exhibits little variance from office to office (Wade, et al. 2003). In general, the largest proportion of energy use in the service sector by end use is heating, which accounts for 45% of the energy used, hot water 9% and lighting, which makes up 21% of the end use energy consumption (National Statistics 2011).

GUINNESS CARBON FOOTPRINT

The Guinness partnership has a total of 38 offices that it owns and leases with a large majority of its offices expected to be performing well below optimum levels, prior to commencement of the KTP programme detailed carbon assessment of its office portfolio had not been carried out. It is essential that energy and carbon dioxide emissions from its office portfolio was established to serve as a datum from which any energy and CO_2 emissions savings could be measured. For the year of 2011, total gas consumption was 1,230,776 kWh and total electricity consumption was 3,192,206, and associated CO_2 emissions of 226,463 kg and 1,736,560 kg respectively as shown in Figure 1 below. It would be expected that the gas consumption of The Guinness Partnership's office stock would be greater than the electricity consumption as the majority of energy consumed in an office building is due to space heating and hot water as previously stated. However, 53% of the Partnership's office stock uses electric space heating, whilst many of the offices that use gas boilers to provide space heating, still use electricity to generate hot water. The Guinness Partnership also has in-house IT services with the Partnership's largest office housing a server room, which contributes over 1 million kWh per annum to the electricity consumption.

 ISBN: 978-1-84219-840-7 .

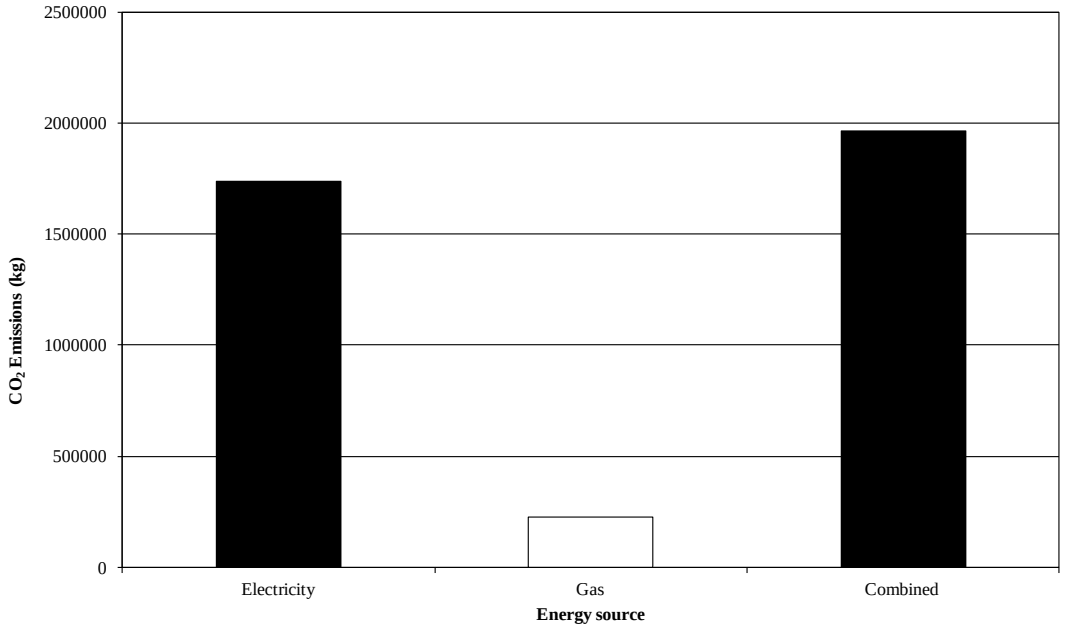

Figure 1 Histogram to show total annual CO_2 emissions of the Guinness Partnership office stock

Office stock type

The condition and construction type of the Partnership's offices is highly variable preventing a one-size-fits-all approach to eco-retrofit. Furthermore the stock portfolio contains some difficult to treat buildings including those constructed with solid masonry building fabric. It was the one of the aims of this project to select different building typologies and tenures in order to learn from the eco retrofit process and to apply this when it comes to the full roll out of eco retrofit to whole of the office stock. Analysis of the office stock highlighted that 64% of its office buildings were owned and 36% leased. Leasehold buildings pose some challenges due to the structure of commercial leases (Wade, et al. 2003), although some leases such as full repair and refurbish leases offer the flexibility of tenants to instigate interventions as they deem fit. The remaining duration of the lease is a key factor in selecting interventions measures and ensuring payback periods fall within the duration of the lease.

The performance of buildings is influenced by many factors some of which include the efficiency of installed space heating systems, climatic conditions and the building fabric (BPIE 2011). Of these the building fabric and age of construction has a major impact on energy performance. The whole of the Guinness office portfolio was categorised in terms of construction date and the results of this analysis is shown in Figure 2 below.

 ISBN: 978-1-84219-840-7 .

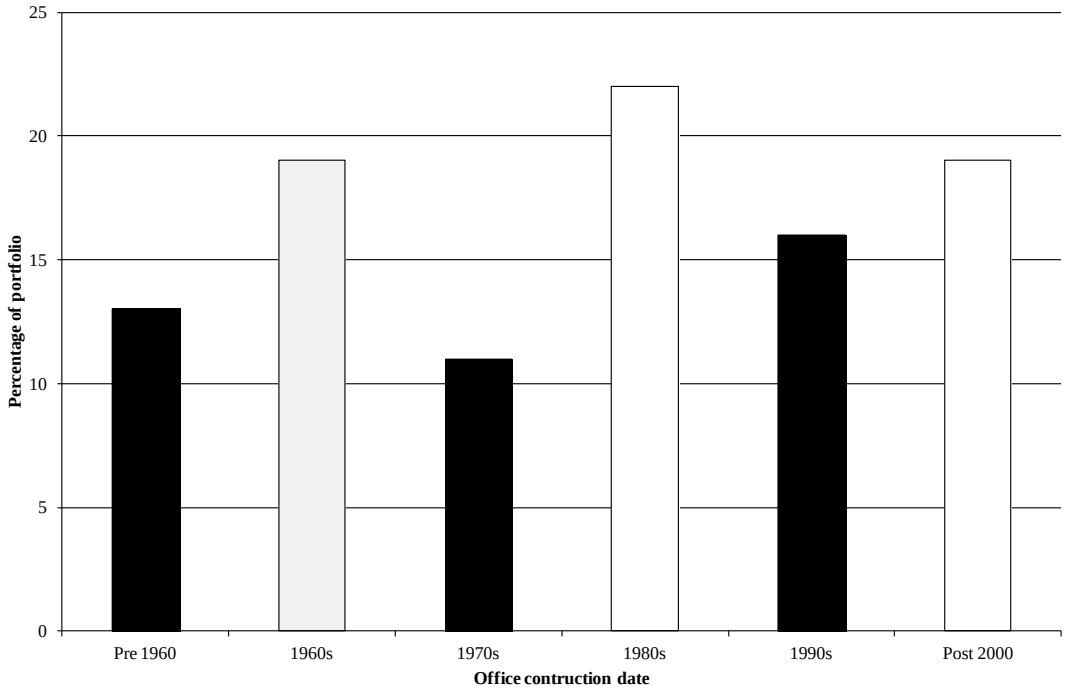

Figure 2 Histogram to show office proportion by date of construction

The date of construction is a reflection of the Building Regulations that were in place at the time and the thermal performance of the fabric required to comply with the regulations at that point in time. The Building Regulations did not come into force before 1966 and 1985 saw the switch over to the more modern system of Building Regulations and Part L2 Conservation of Fuel and Power in buildings other than dwellings. Analysis of the office stock indicated that 43% of the portfolio was constructed prior to 1985 with thirteen percent of the office stock being constructed pre 1960s and these may be defined as "difficult to treat buildings". BRE (2008) define a hard to treat building as one "for whatever reason, cannot accommodate staple, or cost effective fabric energy efficiency measures". It is clear that the portfolio presented some challenges but also great potential for improvement.

BENCHMARKING

An internal and external benchmarking exercise was carried out on the office portfolio as these can be used in order to identify buildings that need closer scrutiny or to highlight problem areas in buildings (BRECSU 2000) The offices were ranked in order of energy consumption per m^2 (GIA) for both electricity and gas consumption. As the phase one pilot scheme is aimed to produce the greatest insight into the rollout of retrofit across the whole of the office stock, it was important to select offices of varying performance. This will help to produce a business case for implementing energy efficiency improvements to all offices rather than only the offices that are performing poorly. Energy benchmarks were taken from CIBSE (2008) and used to compare The Guinness Partnership offices to a 'typical office'. Analysis of the benchmarking data highlighted that 62% of The Guinness Partnership's offices consumed more electricity per m^2 annually than a 'typical office' whilst of the offices that have a gas supply 63% consumed more than a 'typical office'.

OFFICE SELECTION

The phase one of the office retrofit programme involved the selection of four offices, which were capable of delivering significant energy/cost savings whilst ensuring that they represent a broad spread of building types. The programme was divided into two phases so that lessons learnt during phase one could be applied to phase two with the documentation of the process and development of training materials that will be used to embed the eco retrofit capability within the organisation.

The following selection criteria was formulated: a range of performance according to the benchmarking exercise, minimum occupancy of 20, variety of building typologies, no conservation areas, variety of office tenures, avoidance of recently refurbished offices, priority towards offices due to undergo refurbishment. The four offices selected and their attributes are shown in Table 1. In terms of benchmarking, it can be seen from Table 1 that in terms of electricity two of the offices's energy consumption were almost three times that of the appropriate benchmark. In terms of Bower House, this can be attributed to housing the servers for the whole of the Guinness Partnership. Henshaw House's high electricity use is attributed to the fact that its space heating is provided by electricity. All of the offices gas consumption were far higher than the benchmark some more than double. In terms of benchmark CO_2 emissions all of the offices emit higher emissions when compared to the benchmark which is expected for Bower House and Henshaw house due to their high electricity use and the carbon density figure of electricity of 0.544 kg CO_2e/kWh (AEA 2010) which is far higher than the figure for gas of 0.184 kg CO_2e/kWh (AEA 2010).

	Bower House	**Henshaw House**	**Havant**	**High Wycombe**
Annual Energy Costs (2011)	£169,132	£29,775	£14,292	£15,613
Electricity consumption per m^2 (2011)	307kWh	291kWh	122kWh	103kWh

Table 1 Phase one office selection

 ISBN: 978-1-84219-840-7 .

POST OCCUPANCY ANALYSIS

Post occupancy evaluation (POE) is often associated with new buildings however POE can be also refer to a general term for any exercise that seeks to obtain feedback on the performance of an occupied building (Jaunzens, et al. 2003). It was deemed essential to try to understand how the users view the performance of the building to gain a better understanding of how the building is currently performing and how energy is used, before proposing any intervention measures. Occupant behaviour and activities are a major influence on the total energy consumption of a building (Yu, et al. 2011). The occupants of all of the Phase One offices received an electronic questionnaire via Survey Monkey. Some of the key findings can be found in Table two.

	Bower House	Henshaw House	Havant	High Wycombe
How would you rate thermal comfort in the summer between 08.00 - 12.00 1 = very cold 5 = very hot (Overall Score)	3	3	3	3
How would you rate thermal comfort in the summer between 12.00 - 17.00 1 = very cold 5 = very hot (Overall Score)	3	4	4	4
How would you rate thermal comfort in the winter between 08.00 - 12.00 winter 1 = very cold 5 = very hot (Overall Score)	3	3	3	3
How would you rate thermal comfort in the winterbetween 12.00 - 17.00 1 = very cold 5 = very hot (Overall Score)	3	2	3	3
How much control do you feel you have over your thermal comfort 1 = none 5 = total control (Overall Score)	1	1	2	3
How do you rate the quality of the lighting at your desk 1 = very poor 5 = very good (Overall Score)	4	3	4	4
How do you rate the level of lighting control at your desk 1 = very poor 5 = very good (Overall Score)	1	1	3	1
How would you rate the level of natural light 1 = very poor 5 = very good (Overall Score)	5	5	5	4
How would you rate the quality of air in your office 1 = very poor 5 = very good (Overall Score)	3	1	3	2
How would you rate the amount of control you have over the air quality 1 = very poor 5 = very good (Overall Score)	1	1	2	3

Table 2 Summary of post occupancy analysis results

Some of the parameters that influence occupant satisfaction with their environment are; thermal, visual and acoustic conditions (CIBSE 2007) and a major focus of the questionnaire was establishing how the occupants rated their current thermal environment. It is widely established that thermal comfort is subjective and that the best you can realistically aim to achieve is a thermal environment that satisfies a majority of the occupants (HSE 1999). Analysing the findings of the survey three of the offices reported that the thermal comfort rating in the summer between 12.00-17.00 was hot. This could be an indication of unwanted solar gain, that the thermal mass of the building had reached its full storage capacity and so the temperature within the internal space had started to rise or that heat emitting devices such as printers or photocopies are in close proximity to occupied spaces. In view of this information intervention strategies that may be considered could be the installation of

solar shading devices, the use of natural or mechanical ventilation, the use of night time cooling or moving heat emitting equipment to well ventilated areas of the building preferably on the North elevation of the building (Carbon Trust 2010). When the occupants were asked what they would do if the temperature were too high the responses ranged from opening a window, changing the air conditioning settings or using a desk fan, which was a popular answer and increases the summer time electricity consumption. The control over the thermal comfort was cited as none by two of the offices and whilst this reflected in one of the offices poor rating of thermal comfort the other office was air conditioned and the thermal comfort rating was neither hot or cold. A perceived or actual lack of control was common theme in the questionnaire responses with three of the offices stating that there was no control over the level of lighting at their desk and three of the offices stating that they had none or little control over the air quality in the offices. A lack of control over the lighting levels can result in an occupied space being overlit at some times of the day resulting in wasted energy. The lack of control over the air quality in one of the buildings can be attributed to the fact that it is air conditioned and is also linked to the feedback about no control over the thermal comfort. The provision of control is sometimes at odds with the goal of energy conservation with some authors claiming that occupants are the weakest link any energy conservation drive (Masoso and Grobler 2010). However, it has also been argued that if occupants are able to adapt their internal environment to suit their own requirements then they are less likely to suffer discomfort (Nicol and Humphreys 2002). Furthermore, there is a correlation between lack of control over the environment and occupant intolerance of discomfort (Scrase 2000).

FUTURE WORK

A measured survey and energy audit will be carried out on each Phase 1 offices. The energy audits will be used in conjunction with the POE to analyse energy consumption and propose energy interventions. The measured survey data will be used to build a model of the offices in the thermal simulation programme IES. This software will be used to quantify energy savings from any proposed interventions and to build a business case to fund the work.

CONCLUSION

Energy reduction measures have been largely overlooked in the service sector due to issues including tenure and the fact the energy consumption in terms of overall costs is only a small proportion of total costs. However, commercial offices account for 9% of final energy consumption in the UK and so it can be seen that this sector still offers significant potential for improvement. The current KTP project aims to reduce the energy use and carbon emissions from the Guinness Partnership's offices and in doing so reduce the carbon footprint and running costs of the Trust's office stock, delivering cost savings to the Trust. Furthermore, the successful conclusion of this project will build upon The Guinness Partnership's reputation for genuine environmental credentials and adhere to the Guinness Partnership's ambitious sustainability policy.

A TOTAL MANAGEMENT STRATEGY FOR CONTROL OF LAND USE IN HONG KONG

Terence Lam[1] and Henry Man[2]

[1]*Senior Lecturer, Department of the Built Environment, Faculty of Science and Technology, Anglia Ruskin University, Chelmsford, UK*

[2]*Graduate, Department of Building and Real Estate, Hong Kong Polytechnic University, Hunghom, Hong Kong*

ABSTRACT

Illegal change of use in aged industrial and residential buildings is now a problem in Hong Kong. This research aims to develop a management strategy for an effective control of land use in a highly dense environment. Multiple cases were qualitatively analyzed, based on documentary analysis of the court proceedings. In Cases 1 and 2, land lease conditions for restriction to industrial purposes in aged industrial buildings were found to be obsolete and not economically viable, thus resulting in illegal conversion of the premises for commercial use. Cases 2 and 3 showed that ambiguity in user clauses in land leases could lead to illegal change of use from industrial or residential to commercial activities. Most importantly, Cases 1 and 3 demonstrated that tight resources for lease enforcement are the fundamental cause of the problem. Cases 4 and 5 proved and inferred that property managers could effectively take legal action against change of use in high rise buildings with multiple ownerships. A total management strategy should be adopted. The government land management system should work in partnership with private property managers which are empowered under the Deed of Mutual Covenant (DMC) of multiple occupied buildings to take instant action against individual owners for breach of lease conditions. The system should also allow lease modifications, as well as review and clarify any ambiguous user clauses.

Keywords: change of land lease conditions, highly dense environment, land and property management

INTRODUCTION

Land is a scare resource so it is important to have an effective management system to make sure that the land is used according to the statutory planning and land grant conditions, and that allocated land uses can be maintained at an optimum level (Nissim, 1998).

All lands in Hong Kong are virtually held under leasehold tenures. Leasehold tenures are granted by the Lands Department in three ways: public auction, tender or private treaty

[1] t.lam@anglia.ac.uk
[2] henrymankh@yahoo.com.hk

grant. Land is granted to the lessee (land owner) by the lessor (government) and the lease conditions, either by deed and conditions of sale/grant/re-grant/extension, regulate the lessee in respect of the land use. Once irregularities are detected by the Lands Department through public complaint or departmental referral, a series of lease enforcement action would be taken by the Department. The Lands Department (2011a) clearly indicates that the Department has a mission to strive to achieve excellence in land administration and optimum land use for the greater benefit of the community. According to its 2010/11 performance pledges, one of the visions is to ensure an effective enforcement of land use. To this end, all District Lands Offices have lease enforcement teams to inspect premises upon complaints on a breach of lease conditions (Wong, 1998). Actions include registration of the warning letters at the Land Registry, commonly known as "imposing an encumbrance", or pursue legal action against the lessee.

Despite of this, breaches of lease conditions are still a common problem in Hong Kong. There have been many conflicts between the Lands Department and lessees arising from enforcement of lease conditions. A number of cases have ended up in court (Nissim, 1998). For example, some lessees have changed industrial premises into flats, or even converted residential premises into retail shops. Illegal sub-division of flats into smaller units is now a common problem, which affects building safety and has drawn a lot of public attention, as shown in a tragic fire which broke out in an 8-story building in 2011 resulting in several casualties (Ho, 2011).

How should the lease enforcement system be improved for an effective control of illegal land use in occupied premises? A review of recent literature review indicates that previous research has mainly focused on the impact of land lease conditions on property values, and there is a lack of research on the lease enforcement system in Hong Kong. This research therefore aims to develop a management strategy for an effective control of land use in a highly dense built environment, with high rise buildings in multiple ownerships. Such a strategy will address the key issues causing lease enforcement problems from a management perspective.

LITERATURE REVIEW

Economic Issue

The Lands Department enforces lease conditions pursuant to the user clauses in Crown Leases and New Grants which could be executed more than 50 or even 100 years ago, when the built environment, town planning requirements, building regulations and demography were completely different from today. Lai, *et al.* (2010) point out that illegal change of land use in obsolete industry buildings is an inevitable problem and this complicated issue needs to be resolved.

The most common form of contravention of lease conditions in industrial premises is a breach of the 'industrial purposes' restriction. As most of the lessees of the industrial buildings take the advantage of the incentives such as low labour wages, low land rent and tax concessions allowed by the 'Open Door Policy' of China, their industrial activities have been relocated to Mainland China since the early 1980s. Consequently, many industrial buildings governed by industrial leases have been left vacant. Illegal changes in the use of

these premises for other purposes such as stores, band rooms and residential units have gradually become a common phenomenon since the 1980s.

This problem has been seriously criticized by the local media. As reported by Ming Pao Daily (2011a) and (2011b), an industrial building in the deprived Tai Kok Tsui district was built in the 1950s without lift installation and subject to dilapidation. The rental value of recently developed industrial buildings in the locality was only seven to eight dollars per square foot, so many aged industrial buildings had been left vacant. The vacancy rate of industrial buildings was 8% in 2009, according to the Hong Kong Property Review 2010 (Rating and Valuation Department, 2010). Lessees tend to partition factory premises into residential units to get a higher rental income. Surprisingly, the 4th floor, 5th floor and roof of this industrial building had been partitioned into nearly 30 residential units. Many low-income groups cannot afford the high rents in the housing market, and have no option but to live in a poor condition. The Society for Community Organization alleged that many industrial buildings in deprived areas have been illegally changed into residential use.

The media reports clearly indicate that the conversion of aged industrial premises into residential use is a serious problem due to the fact that the lease restriction to 'industry purposes' has become obsolete. Wisegeek (2011) contends that the fundamental objectives of business organizations are to ensure that their available resources can be utilized to the greatest advantage for long-term profits and that the community where the business is located would benefit. Aged industrial buildings are simply not economically sustainable. Clearly the illegal change of lease conditions is not acceptable. A long-term solution should be considered to allow lease modification so that redevelopment can be undertaken to accommodate new uses by owners or developers. The premium for a lease modification is assessed by the Lands Department on the basis of the enhancement in land value as a result of the modification (Lands Department, 2011d). However, the top-up premium nowadays could be unaffordable because of the high land prices in Hong Kong. Using an econometric model of residential property prices in Hong Kong, Craig and Hua (2011) find that the high prices are driven by limited land supply, coupled with rapid rise in real GDP and domestic credit growth as well as the recent negative real interest rate. This means that unless the government is flexible in the assessment of the premium, it can be unaffordable, hindering change of use of premises or redevelopment.

Resources Issue

As reported by Oriental Daily News (2009), an industrial building at Bedford Road had been converted for residential use. In 2007, the Lands Department discovered that this building had been changed for residential use but no further lease enforcement action was taken. After two years, that is, in 2009, no improvement had been made and the extent of the illegal change of use became even worse. The third floor had been partitioned into twenty units with a communal living area, kitchen and lavatory. A councilor of district council pointed out that the conversion of vacant industrial buildings into residential units was a serious problem, but unfortunately the Lands Department did not have enough resources to tackle it.

In response to a query on insufficient resources for lease enforcement, it was reported by the Lands Department (2011b) that the number of lease enforcement cases tackled over the

last three years was 891 in 2009, 904 in 2010, and 900 in 2011. The number of cases handled was relatively constant due tight staff resources. To strengthen its efforts, the Department focused on the more complicated cases in 2011/12. According to Lands Department (2011c), the estimated expenditure for land control and lease enforcement was HK$100.5 million in 2011/12, with around 250 staff. With this substantial expenditure for land management, there is no doubt that the government intends to restrain from further increase in resources.

In the highly dense environment in Hong Kong, high-rise residential, commercial and industrial buildings are primarily sub-divided into multiple ownerships, with property managers being appointed by the owners' corporation (OC) and responsible for managing both the common and the private parts, using the power under the 'Deed of Mutual Covenant' (DMC).

The OC is formed by all members of the building. Pursuant to Section 18(1) of the Building Management Ordinance (BMO), the OC has duties and power to manage and maintain the common parts of the building, and do all things reasonably necessary for the enforcement of the obligations contained in the DMC in respect of control, management and administration of the building (Home Affairs Department, 2011). The OC may appoint a property management company or other professional firms to assist in carrying out its duties. So the property manager, being an agent of the OC, has the legal power to discharge the duties of the OC, and such power is explicitly stated in the DMC.

According to HKIS (2008), the DMC is a private contractual agreement binding all the co-owners and its objective is to set out clear rules and restrictions that property owners, tenants and occupiers must follow in respect of using the common part, private areas and facilities of the development. It comes into effect on the date of execution by the developer and the purchaser of the first unit of the building and is binding on other subsequent purchasers. One of the covenants, as introduced by Legal Advisory and Conveyance Office (2006), is that all owners and the property manager must covenant each other to comply with the land grant conditions so long as they remain as owners or manager. This means that property managers now have the additional power to take action against individual owners for breach of lease conditions. Although the lease enforcement action is still primarily vested with the government (Lands Department, 2011a), this mechanism of allowing property managers to take legal action against illegal change of land use can be regarded as a second tier of management control to supplement the government's tight resources.

Other Issues

Besides, there are occasions where lessees, sometimes occupiers, are alleged to be in breach of lease conditions and when lease enforcement action is taken against them, they challenge the action in court, based on the ambiguity in lease conditions (Nissim, 1998).

In a press release to address the problem of sub-division of flats into smaller units for letting, the Hong Kong Institute of Surveyors advises that both the building management and housing policy should be considered to provide a long-term solution to eliminate illegal change of land use (Ho, 2011).

HYPOTHESES AND RESEARCH METHODOLOGY

The literature review indicates that the existing lease enforcement system should be improved. It was hypothesized that:

1. Lease restriction to 'industrial purposes' in aged industrial buildings has become obsolete. Such buildings are not economically sustainable to run, thus resulting in illegal change of use.
2. Government resources for lease enforcement are not sufficient.
3. Some lease conditions are ambiguous in defining the exact land use, thus resulting in difficulties in enforcement.
4. Government resources can be supplemented by property managers using the power granted under the DMC for control of land grant conditions.

This research focuses on the use of management measures to improve the existing lease enforcement system. The provision of more affordable housing for lower income group to tackle housing shortage and illegal change of premises to residential use is not covered by this study, and this should be treated as a separate issue for further research.

Owing to the fact that lease enforcement is a sensitive issue, a qualitative interview with the government officials would not be easy. A court clarification of the exact meaning of a land use is not uncommon when there is a conflict in opinion between the government and the land user (Lai *et al*, 2010). Hence, legal cases related to the change of lease conditions between the lessor (government) and the lessee (land user) can provide some insight and a gist of the reasons causing contravention, and indicate how such a problem can be rectified.

The multiple-case study method, based five typical cases, was used to qualitatively verify the hypotheses. These cases are related to the common breaches of land grant conditions in Hong Kong, including the change from industrial purposes to other uses (two cases), the change from residential use to other commercial activities (one case), along the impact of property management on the control of illegal land use in residential buildings (two cases). The use of typical cases to capture every day occurrences is one of the reasons for choosing the case study method (Yin, 2009). Proverbs and Gameson (2008) add that the findings of a typical case will be of relevance to many other similar projects. Fellows and Liu (2008) and Yin (2009) state that case study research can be used to investigate phenomena within a real context and can therefore draw rich conclusions.

A documentary analysis of court cases was deployed to collect qualitative data. Details of the cases were obtained from the Hong Kong Legal Information Institute (HKLII) which provides original information of court cases in Hong Kong with an aim to support and promote the legal system.

FINDINGS AND DISCUSSION

Case 1 (HKLII, 2003): Pak Wai Ching (Plaintiff) v The Secretary for Justice (Defendant) [2003] HKCFI 725

This is a typical case involving an illegal change of use of land from industrial to residential purposes. The plaintiff had owned a unit on the ground floor in an industrial

building since 1978. The land lot was governed by a condition of sale registered in the Land Registry in 1972. The Special Condition 2(a) requires that the premises should be used for either industrial or godown purposes or both.

The Lands Department received a complaint on the premises on 18 April 2000 and subsequently discovered that the premises were used for selling flowers and wreaths to patrons of and visitors to the Hong Kong funeral parlour. Since the flower shop constituted a commercial activity which contravened and breached the lease conditions, the Department issued a warning letter on 31 October 2000 to the plaintiff requesting that she ratify and remedy the breach.

After receiving the warning letter, the plaintiff contended that her use of the premises as a flower shop did not constitute a breach of the lease conditions because the government had waived the acquiescence to enforce the lease conditions for fifteen years since the acquisition of the premises in 1978. The Department had not taken any action until the contravention was first noticed in 1993. The plaintiff hoped that she could continue to use the premises as a flower shop without paying a waiver fee and a premium for lease modification.

As explained by the district estate surveyor, staff resources for lease enforcement were not sufficient, with less than ten staff since 1982. This limited number of staff serves not only Hong Kong East, but also Hong Kong West as well as Hong Kong South.

The court held that selling flowers and wreaths was considered as a commercial activity, which contravened the lease condition.

This case demonstrates a typical lease enforcement problem in Hong Kong. The Lands Department tried to enforce the lease condition registered in the Land Registry in 1972, which was more than thirty years ago. However, such restriction to 'industrial uses' have become obsolete, thus resulting in illegal changes of use. This is in coincidence with the findings of Lai *et al.* (2010). Hypothesis 1 is therefore validated. This case infers that lease conditions should be allowed to be modified to enable economic sustainability for business.

The Lands Department tried to enforce the lease condition after the original industrial use had been breached for 15 years. Apparently, enforcement resources were not sufficient so this validates Hypothesis 2.

Case 2 (HKLII, 2000): Raider Limited v The Secretary for Justice [2000] HKCFA 76
This case is also about change of use of an industrial building to other activity. The appellant (Raider Limited) had owned the premises on 22nd floor of a factory since 1994 and 1995. According to the Special Conditions 2(a) and 2(b) of the land lease dated 14 January 1963, the lessee of the lot was restricted to use the premises for 'industrial purposes' except for offensive trades producing pollutants, and for ancillary uses like offices and quarters for persons employed for building safety and security.

The appellant used the premises for the manufacture of pagers and the provision of a paging service. In 1995, the Lands Department conducted an inspection of the appellant's premises and discovered that the premises were used for providing paging services, which contravened and breached the lease conditions. The owner appealed against the Department's point of view by commencing litigation. His reason was that the use of the premises did not breach and had not breached the Special Condition 2(a) as the primary use of premises was and had at all times been for industrial purposes.

The Lands Department appealed to the Court of Appeal on 7 December 1999 against the previous court judgment which held that the appellant did not contravene and breach the restrictive 'industrial uses' stipulated in the Special Condition 2(a). The Department argued that the paging service provided by the appellant did in fact constitute a breach. The court upheld the appeal because the paging service could not be regarded as ancillary offices or quarters allowed by the Special Condition 2(b). Also, the provision of a paging service could not be perceived as the final process of the manufacturing industrial undertaking. The paging service was separated from the manufacturing of the pagers.

Again the Lands Department tried to enforce the lease conditions of the subject premises pursuant to the Conditions of Sale registered in the Land Registry in 1963, which was more than forty years ago. The restriction to 'industrial purposes' had become obsolete so the lessee changed the use of premises to providing a paging service which was more economically viable. This finding also validates Hypothesis 1.

The appellant alleged that the paging service was ancillary to the manufacturing of the pagers. The user clause of 'ancillary uses' creates an ambiguity and difficulties for the Lands Department to enforce the restrictive covenant in practice. This finding validates Hypothesis 3 and infers that an amendment should be made to The Land (Miscellaneous Provisions) Ordinance, Cap. 28 to clearly define what ancillary uses for industry buildings are in order to plug the loopholes for illegal changes of land use.

Case 3 (HKLII, 2007): Expressluck Development Limited and Best Partner Limited (Plaintiffs) v The Secretary for Justice (Defendant) [2007] HKCFI 755

The plaintiffs alleged that the ground floor of a domestic building could be used for shops or for other commercial purposes. The Lands Department contended that such uses would contravene and breach the Special Condition (c) in Conditions of Exchange No. 3996 registered in the Land Registry in July 1939, which stipulated that the lessee of the lot is restricted to using the land for domestic housing.

The plaintiffs commenced the litigation on the grounds that the restrictive covenant did not restrict the use of the ground floor for commercial purposes and that the plaintiff's ancestor had used the ground floor for a restaurant and other commercial uses since the 1940s. However, the Lands Department had not taken any lease enforcement actions previously so the plaintiff conceived that this waived the restrictive covenant in the lease conditions.

In 2003, the Lands Department confirmed that the plaintiffs' proposed residential redevelopment, with the ground floor used as a play area and gymnasium for the residents, was acceptable under the restrictive user covenant because the redevelopment would be

basically used for residential purposes. After the redevelopment was completed, the plaintiffs used the ground floor for a shop so the Department took legal action against them.

The plaintiffs contended that the use of the lot did not contravene the restrictive covenant. The restrictive covenant only restricted the type of building to be erected, but not on the use of the lot. Besides, the 20-storey formed a large portion of the domestic ration in the lot. The use therefore did not deviate from the lease condition. However, the court held that the plaintiffs could not use the ground floor as a shop because the whole building should be used for domestic use, not just a large portion.

This case shows that the ambiguity in lease conditions, that is, in the erection of domestic houses, provides loopholes for land users to change the land use. This finding confirms the validity of Hypothesis 3 that ambiguities in defining lease conditions does pose problems in land use and difficulties in enforcement.

The case also demonstrates that the government's enforcement resources are not adequate. The plaintiff argued that their ancestor had used the ground floor for a restaurant and commercial uses since the 1940s. In the 1980s, the plaintiffs at last did not regularize the use as a congee and noodle shop but no lease enforcement action had been taken since then. So the plaintiffs conceived that this waived the restrictive covenant. This finding validates Hypothesis 2 that government resources are not sufficient.

Case 4 (HKLII, 2010a): Goodwell Property Management Ltd (Plaintiff) v Ng Shung Kwok Dickson and Other (Defendant) [2010] HKDC 107
In this case, the plaintiff was the property manager of a residential development, whereas the defendants were the registered owners of Flat B on the ground floor and the adjacent flat roof adjacent to Tower 3. The plaintiff claimed for an injunctive relief against the defendants in respect to the structures erected on the property, based on the reason that this was in breach of the DMC of the estate.

Between October 2004 and September 2006, the defendants erected a canopy structure on the larger flat roof, and altered the entrance to the smaller flat roof by removing the gate and erecting a door-like structure. No written approval for undergoing the said renovations was given by the plaintiff at any time.

Clause 17 of the DMC provides "No owner shall do or permit to be done any act or thing which may or will alter the external appearance of the Estate or any part thereof" and Clause 25 reads "…… Without prejudice to any other provision in this Deed the Owner(s) for the time being of the flat roof(s) or the roof(s) of the Estate shall not erect, affix or install or cause or allow to be erected affixed or installed any structure on such flat roof(s) or the roof(s) save and except with the prior written approval of the Manager ……"

The defendant alleged that it was necessary for the canopies to be constructed for protecting people from being hit by objects falling from above. However, the court held that the defendants were bound by the provisions of the DMC so there was no defense for them to abate the incidents of falling objects from a height by breaching their own obligations under the DMC.

This case involved a change of roof spaces into an enclosed home. Although the case did not involve a material change of land use from one type to another, it does infer that if there is any breach of the DMC covenants, property managers can effectively take legal action against individual owners. As the Legal Advisory and Conveyance Office (2006) introduces a covenant to the DMC that all owners and the property manager must covenant each other to comply with land grant conditions, property managers now have the additional power to control illegal changes of land use. As such, property managers can supplement government resources for lease enforcement and this validates Hypothesis 4.

Case 5 (HKLII, 2010b): Central Management Ltd (Plaintiff) v Light Field Investment Ltd and Another (Defendant) [2010] HKCFI 22

The plaintiff, a property manager of a high rise residential building, took legal action to restrain the owners of two adjoining flats (defendants) from removing the structural parts of a partition wall between the two flats on 53rd floor.

The plaintiff successfully claimed that the structural wall was part of the common areas and facilities defined by the DMC, which "means and includes … low-bearing walls, foundations, columns, beams and other structural supports of the Development", and by the BMO, which refers to "the whole of a building, except such parts as have been specified or designated in an instrument registered in the Land Registry as being for the exclusive use, occupation or enjoyment of an owner".

The court also pointed out that Clause 37 of the DMC gave the power and obligation to the plaintiff to manage and keep in good order and repair all common areas and facilities.

Consequently, it was decided by the court that the structural part of the partition wall separating the two units unit was part of the common areas and facilities as defined in the DMC. An injunction was granted to restrain the defendants from removing, altering or making any opening in the structural part of the said partition wall.

All co-owners should follow the DMC covenants and property managers have the power to enforce such restrictions, as spelled out by the HKIS (2008) and the Home Affairs Department (2011). Again this case demonstrates that property managers can effectively take legal action against individual owners for illegal land use, using the DMC power and the related covenants. This validates Hypothesis 4.

Summary of Validation of Hypotheses

Cases 1 and 2 verified that lease conditions for restricting land use to 'industrial purposes' in aged industrial buildings had become obsolete, thus resulting in illegal changes of use to commercial activities (Hypothesis 1). Cases 2 and 3 showed that ambiguities in the user clauses of land leases could lead to illegal changes of use from industrial or residential purposes to commercial activities (Hypothesis 2). Most importantly, Cases 1 and 3 demonstrated that the lack of sufficient resources for an effective enforcement is a fundamental cause of the problem (Hypothesis 3). Cases 4 and 5 proved and inferred that property managers could effectively bring legal action against illegal land use in buildings with multiple ownerships, using the power under the DMC (Hypothesis 4).

CONCLUSIONS

The multiple-case study indicates that illegal changes of land use are a common problem in high rise buildings in Hong Kong. In aged industrial buildings, the typical change is from industrial to commercial or residential use. Residential buildings are often changed to commercial use on the ground floor and the rooftops are frequently changed to enclosed spaces. Government resources for lease enforcement in a highly dense environment are not sufficient, but property managers can effectively supplement them by controlling land use through the use of their power under the DMC.

The Legal Advisory and Conveyance Office (2006) introduces a restrictive covenant to the DMCs that all owners and the property manager must covenant each other to comply with the land grant conditions. As this only applies to the new DMCs created in and after 2006, it is recommended that the BMO should be amended so that the covenant is also applicable to the existing ones formed before 2006. Consequently, property managers can supplement government enforcement resources in all cases. The government should form a strategic partnership with private property managers, and encourage them to take instant action if necessary.

In addition to this, the land management system should be flexible to encourage and allow lease modifications from industrial to other uses by owners or developers, and the amount of premium required should be affordable. The system should also review and clarify any ambiguous user clauses through amendments of the related Land Ordinance.

A total management strategy should be adopted for an effective control of land use, comprising an enforcement partnership formed between the government and private property managers, flexibility in lease modification and clarification of ambiguous user clauses. The results of this study are derived from five typical cases, but they form a baseline upon which further research can build to test their significance in many other settings. Ultimately, a more robust management strategy can be developed for ensuring an effective control of land use.

INFLUENCE OF LANDSCAPE CHARACTERISTICS OF THE LAGOS LAGOON ON URBAN TOURISM DEVELOPMENT

Nnezi Uduma-Olugu[1] , Jerry Obiefuna[2] and Olaniyi Okedele[3]

ABSTRACT

The Lagos Lagoon is a major geographical feature in Lagos, being the largest of the network of lagoons that stretch from Republic of Benin through to the Nigerian Niger Delta. Parts of the lagoon waterfront have degenerated into slums, with mainly shanties at various points, wood preservation, markets and sand dredging activities, robbing the area of potential urban tourism revenue. Growing statistics indicate financial gains in exploiting water tourism. In recognition of this, the Lagos Government is pursuing an aggressive tourism and waterfront development strategy for Lagos Metropolis. To determine the place of landscape features of the Lagos Lagoon on its viability for tourism, the research evaluates the lagoon's landscape characteristics and answers questions of landscape perception of the area, identifying other factors which may be of relevance to its tourism development. Using structured questionnaires with pictures of the landscape features of the lagoon, field survey and interviews, the study identified the communities, problems, and factors influencing tourism development. Results show that the landscape characteristics of the lagoon have a very significant effect on tourism development. It identified the availability of beaches, nature of adjourning land-uses and proper planning of the area as major factors influencing its tourism development.

Keywords: Lagos lagoon, landscape assessment, landscape perception, urban tourism, water-based recreation.

INTRODUCTION

The place of tourism as an engine for growth and an economic driver has been much emphasized, especially in developing countries such as Nigeria and Ghana (Uduma-Olugu and Iyagba, 2009; Akyeampong, 2011). Previous studies demonstrate that

[1] nnezi.udumaolugu@gmail.com
[2] jerynus@yahoo.com
[3] okedeleolaniyi@yahoo.com

residents feel urban tourism helps the economy (Ritchie, 1988), that tourism increases the standard of living of host residents, and that tourism helps the host community and country earn foreign exchange (Ahmed & Krohn, 1992). Also, tourism helps generate employment (Milman & Pizam, 1988; Ahmed & Krohn, 1992; Backman & Backman, 1997), and increase revenue to local business (Sethna & Richmond, 1978; Backman & Backman, 1997) and shopping facilities (Backman & Backman, 1997). This spirals into the economy of the larger society. Some research has been done on general issues of tourism in Lagos (Uluocha, 1999; Oshundeyi and Babarinde, 2003; Adejumo, 2005; Uduma-Olugu and Iyagba, 2009; Adejumo, 2010, Uduma-Olugu and Onukwube, 2012). Prior to this study there has not been any research directly measuring the public perception in connection with tourism development in Lagos.

Urbanization and Tourism

Lagos Nigeria, the coastal former capital city and commercial nerve center of the nation is beset with problems typical of such large cities of the world. Urban sprawl and its attendant demand for space is among such problems. While the city's ubiquitous water bodies and ecosystem offers vast opportunity for its development for tourism, unrestrained and insensitive development has impacted negatively on it thereby curtailing its potentials. Indiscriminate reclamation of wetlands, encroachment on river banks and lagoons, slum housing, deforestation poor spatial planning and land speculation (Abegunde, 1988; Oduwaye, 2009) are some of the ills unleashed on the urban center. Lagos is very important as a tourism destination in Nigeria. The region's high standing in the tourism sector is based on its large stock of tourism resources which range from sandy beaches and ecological and cultural resources to historical heritage. Among its many resources are a stock of different water bodies and waterways of which the Lagos Lagoon is one. The Lagos lagoon is the focus of this study. It is located in the heart of Lagos state, fed by several rivers and empties through the Lagos harbour to the Atlantic Ocean (Nwilo, Peters & Badejo, 2009). Inspite of the huge potential that exists for tourism, these resources remain largely untapped (Uduma-Olugu and Iyagba, 2009; Adejumo, 2010).

The study hopes to highlight the gains of a cleaner, unpolluted lagoon by exploring the perception of tourists and users of water tourism venues within the Lagos Metropolis towards the enhancement of the landscape resources of the lagoon for tourism. Currently, water is being mismanaged, as effluent and all manner of waste is pumped directly into the existing water bodies in Lagos, particularly the Lagos lagoon (Onyema, 2009). Its water is used as a disposal agent while its more valuable uses as a major asset for tourism and recreation is not being fully explored. Previous research, indicate that water tourism can be a major revenue source, particularly for developing economies like Nigeria (Visser & Njuguna 1992; Falade, 1998). This calls for change in the way the existing fringes of the Lagos waterways are currently being used.

Landscape Perception issues

Many factors can affect tourism development and the landscape of the place is one of the relevant determinants of why a tourism destination is perceived as attractive. One of the key indicators of a place's character, is its landscape – comprising not only of the landcover and landscape quality, but also of its very essence which can be captured when the landscape is assessed and evaluated, using pre-determined parameters (Swaffield, 1999). Corriera & Pimpao (2008) in their study confirmed that the landscape is one of three pull factors of motivation that influenced a tourist's

 ISBN: 978-1-84219-840-7 .

choice of a destination. The basis of landscape perception for landscape assessment was laid by early studies by that K. Craik. L. Leopld, B. Linton, E. Shafer, J. Wohwill and E. Zube in the United States and K. Fines and his colleagues in Britain conducted pioneering studies in landscape perception and assessment during the late sixties (Ndubuisi, 2002). The study is necessary to examine the public perception of the Lagos lagoon and its potential as a tourism and landscape resource, from the point of view of its landscape characteristics. Its major aim is to measure the public's perception of the landscape characteristics of the Lagos lagoon, as it influences tourism development. To achieve this, the following objectives will be pursued;

1. To identify the primary users of the Lagos Lagoon tourism destinations
2. To examine tourists and visitors' perception of the landscape characteristics of the Lagos Lagoon
3. To determine which of the landscape characteristics of the Lagos Lagoon has an influence on its tourism development.

Study Area

The Lagos lagoon is the biggest of nine lagoons stretching from Republic of Benin to the Nigerian Niger Delta. Nwilo, Peters, & Badejo (2009) described the boundaries of the Lagos lagoon; the Southern margin of the Lagos lagoon is bounded by the Five Cowrie Creek, the Eastern margin by the Palaver Islands and the Northern border by Ikorodu. The lagoon is 40 - 64km long and has two arms: one connects the Lekki lagoon while the other leads northwards into the hinterland. The lagoon is fed mainly by the rivers of Ogun, Shasha, Oshun, Agboyi and Maijidun, the Ogudu creeks and waters of Epe and Lekki lagoons. Various activities go on in the lagoon. These include; transportation, sand mining/dredging, wood preservation, refuse disposal, slum housing, high income housing, markets, fishing, jetties, natural vegetation, rural housing, urban commerce, urban waste water drainage, recreation, institutional, etc.

The settlements that make up the Lagos lagoon waterfront are varied and contribute to its landscape characteristics –some are rural, others are urban while there is also a mix of urban and natural vegetation. These are interspaced with uninhabited swampy mangrove vegetation. Also along some of the waterfront abutting the Lagos lagoon, are shanties built on the water using makeshift materials, as well as wood preservation and sawmill market particularly at the Makoko and Okobaba end that generally deface the waterfront and make it unattractive for water tourism or recreation. The Third Mainland bridge of Lagos also traverses this lagoon, making it even more important and key landmark in the Lagos landscape.

 ISBN: 978-1-84219-840-7 .

Figure 1.1: The Communities adjourning the Lagos lagoon shores

METHODS

Pictures of various aspects of the lagoon were taken and shown to respondents in three water-based tourism locations within the lagoon (University of Lagos Waterfront, Ipakodo Origin Zoo and Jetty, Ikorodu and Lekki Phase 1 clubhouse – the Pavilion), and three more popular locations along the Lagos coast (Bar Beach, Maiyegun/Gbara Beach (formerly Lekki Beach) and Alpha Beach). Out of 600 questionnaires, only 422 were correctly filled and used for the survey. The respondents were asked to rank on a scale of 1 to 5, the most beautiful, to the least beautiful. There were four sets of pictures, with five in each set. The pictures were based on totally urban, open spaces, landscape elements and human/social activities along the shores of the lagoon. The questionnaire contained other questions bothering on the respondents perception of the landscape characteristics of the lagoon as well as factors (tabulated, and on a likert scale), they were considered as having differing impact on tourism development on the lagoon. The questionnaires were distributed by research assistants at the locations on festive days and public holidays when a large population was expected based on an earlier survey (Uduma-Olugu and Iyagba, 2009). The statistical analyses of the data obtained were carried out with the aid of Statistical Package for Social Sciences (SPSS 16).

RESULTS AND DISCUSSIONS

The gender analysis of the respondents from Table 1 show that 65.4% were male while 34.6% were female. The average age of respondents was 28.3 years, out of which the highest number of respondents were mostly youths – aged 16 – 30 years (67.3%). The implication is that to a great extent people that visit such destinations are mostly young, and a lot of them are males. Respondents that fall under these age brackets are believed to have a lot of energy, dynamic and vibrant and are more likely to be engaged in active rather than passive recreation. The highest number of respondents live in Lagos metropolis 66.4%, the tourists – coming from outside Lagos from other towns in Lagos State, other states and other countries make up the balance – 16.8%, 13.3% and 3.6% respectively. This result was expected as the area does not seem to have a high traffic of tourists which is what necessitated the study in the first place.

 ISBN: 978-1-84219-840-7 .

The Nationality of the respondents was also not surprising as 98.1% were Nigerians. Europeans (1.2%), North Americans (0.2%), Middle East (0.2%) and other African countries (0.2%) made up the balance. This clearly shows that tourism is not high at the venues since most of the visitors are Nigerians. The implication is that foreign tourists are not visiting the water-based tourism destinations. The tourism going on in is domestic from other towns within Nigeria.

Variable	Characteristics	Frequency	%	Mean	Total
Gender	Male	276	65.4

Table 1: Summary of Socio-Demographic Variables

Table 2 shows the ranking of the totally urban aspects. In the first set of pictures comprising shots of totally urban aspects of the lagoon, the mean response of all the pictures were above 3.0, indicating that they were all considered beautiful with picture C (showing a high-rise luxury building) having the highest score of 70 and picture B (showing single storey buildings mixed with a lot of vegetation) having the lowest score of 62. Picture C also had the highest score in the entire 20 pictures ranked by the respondents.

Ranking of Landscape Perception of the Lagos Lagoon: LB (Least Beautiful), a (Average), FB (Fairly Beautiful), B (Beautiful), EB (Extremely Beautiful)

For the second set of pictures comprising shots of different landscape elements of the lagoon, Table 3 shows the mean response of four of the pictures were above 3.0, indicating that they were considered beautiful except for picture J which had a score of 2.9. Pictures F (showing grassland vegetation) and picture G (showing only the water) both have the highest score of 64 implying that they were jointly considered the best pictures by the respondents. Picture J (showing mangrove forest vegetation) had the lowest score of 62, as the least liked picture in the group.

Ranking of Landscape Perception of the Lagos Lagoon: LB (Least Beautiful), a (Average), FB (Fairly Beautiful), B (Beautiful), EB (Extremely Beautiful)

For the third set of pictures comprising shots of open spaces around the lagoon, Table 4 shows the scores were generally low. The mean response of three of the pictures were just above 3.0, indicating that they were considered beautiful except for pictures K and M which both had a score of 2.9. Picture O (showing grassland vegetation) had the highest score of 62 implying that it was considered the best picture by the respondents. Pictures K (showing fishing circles) and picture M (showing mixed vegetation) jointly had the lowest score of 60, as the least liked pictures in the group. The two pictures were not considered beautiful.

Ranking of Landscape Perception of the Lagos Lagoon: LB (Least Beautiful), a (Average), FB (Fairly Beautiful), B (Beautiful), EB (Extremely Beautiful)

Table 5 shows the results of the last set of pictures comprising shots of human and social activities around the lagoon, the scores were the lowest in the entire group of pictures. The mean response of only one of the pictures was 3.0 (Pictures T - showing mechanic village amidst a refuse dump), indicating that they were considered barely beautiful. All the others fell below 3.0 showing they were not considered beautiful. The picture with the lowest score in this group was picture S (showing slum housing on stilts) with a score of 50, as the least liked pictures in the group. This particular picture was generally considered least beautiful in this group**.** It also had the lowest score in the entire 20 pictures ranked by the respondents.

CONCLUSION

The results showed that the public perception of the landscape features of the lagoon is average. The respondents did not show a clear appreciation of the natural landscape over the urban aspects of the Lagos Lagoon. Most did not consider the lagoon's landscape beautiful. The picture that was most liked by the respondents was the one showing high rise luxury housing on the shores of the lagoon. The aspect of the lagoon least liked by the respondents were the portions that highlighted the unsightly human and social aspects –including the refuse dumps, mechanic village, wood processing, sand dredging and slum housing. The slum housing picture had the lowest score of the entire twenty pictures they had to choose from. This highlights the issue of slum housing as a major blight and deterrent for the development of the Lagos lagoon for tourism as even the locals identified it as a negative feature of the lagoon. The survey confirmed that the landscape characteristics of the Lagos lagoon influence its use as a tourist destination.

The results also show that 2/3rds of the people using the destinations live in Lagos – indicating that they are used more for recreation, than tourism (which requires travel and overnight stay). Of the remaining 1/3rd, very few tourists were foreigners at the locations surveyed; more domestic tourism is going on in the lagoon, than international tourism. This means that if the government is serious about developing tourism within the Lagos Lagoon, More needs to be done to attract foreigners to the area by providing the preferred facilities which they require. From the results, it appears that the destinations are frequented by middle income, young men below 30 years old. This group of people require facilities that they can engage in active sports or other tasking recreation, as such this should guide the provision of infrastructure to meet this need.

RISK, RESILIENCE AND THE 'KNOWLEDGE CITY'

Simon Huston[1] and Clive M J Warren[2]

[1,2] The University of Queensland Business School, University of Queensland, Brisbane 4072, Australia

ABSTRACT

The 'knowledge city' ('KC') enriches regional development with institutional and environmental domains. Its competitors in the new-economy regeneration stakes are the 'creative', 'green', 'intelligent' and 'smart' cities. All suggest planning foresight but contention surrounds philosophical underpinnings as well as specific recipes. Certainly, new-economy discourse condemns disconnected 'McMansions' and advocates for integrated, precinct-orientated and community-focused property development. But, extra outlays increase costs and only make financial sense if KC projects are de-risked. Here, we look for some indication that KCs inoculate against recession. Notwithstanding conceptual ambiguity, statistical and spatial concern, we investigate the KC resilience claim. Our findings suggest that knowledge-city score, however imperfect, does confers some post-GFC economic resilience but no more than a burgeoning middle class.

Keywords: demographics, knowledge city, new economy, resilience, risk,

INTRODUCTION

Real estate volatility (market risk) is influenced by both capital market and local space market conditions and prospects. Exuberant sentiment, loose credit, and lax fiscal or monetary policy drive capital markets bulls but, fluctuations in growth deter property investors. Economic resilience, indicated by continued output growth or stable unemployment, comforts nervous post-crisis investors and de-risks projects (Roberts and Henneberry 2007). 'Knowledge city' ('KC') credentials or a booming middle class could strengthen resilience in the wake of the Global Financial Crisis (GFC) by stimulating local demand, cutting vacancies and, over the longer-run with planning governance, incentivise the construction of quality buildings (D'Argensio and Laurin 2009). Hence, the research question for this paper is:

'What is a KC and does it confer economic resilience?'

 ISBN: 978-1-84219-840-7 .

TOWARDS A KC MODEL

Institutional property investors concentrate on 'first-tier' cities or knowledge clusters which produce half the world's traded output (Global Metro Monitor 2010; OECD 2010). Such knowledge clusters include Silicon Valley, Cambridge in England or Helsinki. Paul Otlet ([1913] 1990) was perhaps the first to articulate links between cities and knowledge dissemination. In economics, Hayek (1945) put knowledge centre stage and Rothschild and Stiglitz (1976) destroyed comforting notions of equilibrium in a world of imperfect information. Soon institutions such as The Centre for Economic Policy Research(OECD) included knowledge and innovation indicators in their statistics (Benoît 2006; Peters 2009).

Urban variety (Blumenfeld 1955), precludes a 'one size fits all' KC model and narrow technological variants vie with more socially inclusive, pedestrian or 'quality of life' discourses (Wadley 2010; Alves and Ramalho 2011; Goede 2011). Despite its ambiguous 'hard' or 'soft' formulation, governments and cities, under competitive pressure, espouse Knowledge Based Urban Development ('KBUD') (Australian Federal Government 2010). However, as with any collective betterment intervention, KC can be misconstrued, misapplied or misappropriated. Lopsided planning can become a 'sterile monologue of totalitarian power' (Mumford 1961: 211). Hall (1999), in the tradition of Geddes (1949 [1919]: 25) seeks 'civic and regional reorganisation' for social survival and success but favours cultivation of an 'innovative milieu' rather than grandiose planning. Historically, urban utopias, such as 'Fordlandia' and 'New Australia' were dismal failures (Grandin 2009). Planned cities like Brasilia or Abuja, in Nigeria, have become the 'irrational' spatial embodiment of a dysfunctional 'collective contrivance' (Mumford 1961: 622; Brown 2009). New Songdo City in Korea is a modern example of a, as yet, untested technological urban utopia (McNeill 2009). Figure 2 presents one take on the dimensions of KBUD

A necessary condition for a 'KC' is a clean air and water. Other KC domains (so of which are discussed) include:

- Environment
- Governance
- Communities
- Technology
- Urban form

Community

The 'KC' is underpinned by rich communities of educated, tolerant and skilled people who trust each other and share a common purpose (Murphy, 2009). The problem is that fostering human capital is expensive, time-consuming and complex, certainly beyond an electoral cycle. Most, countries lack the political capacity to undertake substantive educational or other reforms. Public-relations manoeuvrings is far easier. Alternatively, structural reform can be short-circuited by bringing in talent. For Florida (2005) tolerance of diverse minorities ignites cultural and commercial creativity. For Landry (2006: 271) talent and tolerance are not enough to spark or sustain a KC's 'creative milieu'. Creativity requires 'multi-faceted resourcefulness' so that 'merely holding [cultural] festivals does not mean a city is creative'. As Scott (2006: 15) states: 'creativity is not something that can be simply imported into the city on the backs of

peripatetic computer hackers, skateboarders, gays, and assorted bohemians but must be organically developed through the complex interweaving of relations of production, work, and social life in specific urban contexts'.

Governance, institutions, policy and technology

While, economic opportunity sparks and technology fuels knowledge cities, if it is poorly governed they fizzle out. Stoking a boom in an engineered city without reform of the spatial political economy merely stirs 'the surface froth and evanescence so characteristic of flexible accumulation' (Harvey 1989: 187). Without the lifeblood of robust institutions and rule of law, a KC withers. Governance ensures collective imperatives do not trammel individual rights and prevents bureaucratic managerialism smothering the entrepreneurial spirit. Fake transposed 'new economy' city blueprints or the 'architectural megalomania' and 'hallucinatory pastiche' of Dubai (Davis 2006: 51) won't work (Hall 1998; Scott 2006).

Some dismiss KC notions as a cynical legitimacy exercise to cover misspending or malignant real estate development. Manipulation of urban form alone is necessary but insufficient to foster substantive innovation. Indeed, questions linger about the significance of place architecture for the transmission of 'tacit knowledge in modern networked society (Castells 1996). One could argue that street life or accidental face-to-face encounters played a limited role in the genesis of revolutionary science for Galileo, Newton, Darwin or Mandelbrot (1983). For Håkanson (2005) most significant information is exchanged and new ideas are generated at work. Policy which facilitates education, training and labour mobility could be more effective at stimulating innovation than grandiose projects to reconfigure city urban form. In this view, KC function evolves from sustained sensible policy, technology diffusion and favourable demographics within robust institutions. Where some KC form intervention is needed, Ho (2000) suggests its mechanics involve the coordination of multiple agencies. To conclude, the KC concept is fuzzy and merges with the creative city within 'new economy' discourse. A KC 'illustrates the complexity of interactions between the micro and macro' (Chapain and Lee 2009: 160). In short, some of the policy architecture (e.g. rule of law and education) for a successful KC is national and there is no local unique KC prescription (Lorenzen 2010).

Urban form

The KC puts constraints on urban form, insisting on walkable or 'convivial' neighbourhoods which are aesthetically pleasing and connected to quality amenities to facilitate intermingling. In a KC, the talented workforce connects seamlessly by foot or on public transport 'community precincts'. These neutral public realms counteract spatial segregation and facilitate community connectedness. In former times, Piazza St Marco in Venice functioned to devolve commercial and political power spatially although now its role is largely a tourist spectacle. Appropriate amenities could include museums and some bars or restaurants where brokers can easily network (Gallo 2010) as well as 'artistic squats' (Vivant 2011). From the wider collective imperative, crass instrumental consumption spaces such as overcrowded malls, bowling alleys, football clubs and movie theatres are no use for the KC (Weber 1958[1905]; Gottdiener 2003; Glaeser *et al*. 2004). In the KC, the social and productive potential of bars, clubs and discothèques varies with their symbolic or sexually coded atmosphere (Knopp 2003). 'Bohemian' bars could conceivably provide conduits to catalyse productive innovation. However, fancy projects disconnected from infrastructure and without a

 ISBN: 978-1-84219-840-7 .

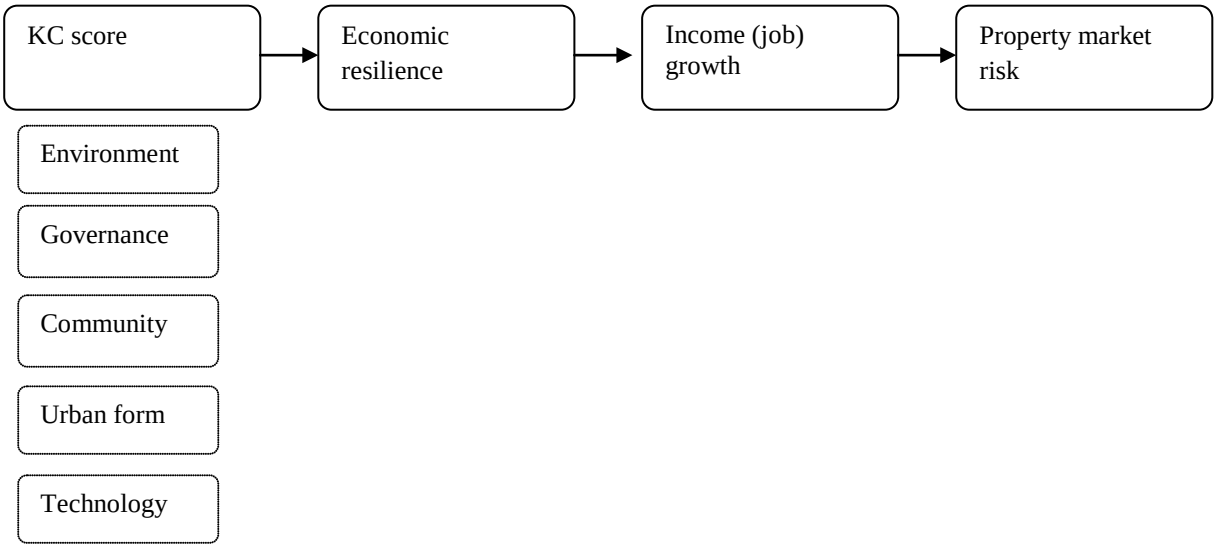
talented clientele, even if decked out in trendy 'European' décor, only purvey a commoditised illusion of liberated social discourse and mask alienation, isolation and desperation (Martinus 2011).

In auditory terms at the street level, the KC generates a 'hubbub', not traffic noise. In fact, in the KC, carefree chatter mingles with informed discourse and music. In a KC, convivial areas are separated from vehicular traffic but not by buildings which affront aesthetic sensibilities. The urban form of the KC is beautiful, but not necessarily in a classical mode. Aesthetics is contextual but proportion or even fractals transcend conventional classical constraints restricting the authenticity of architectural innovation. Places in the KC, are convivial and uncluttered, uplifting and authentic.

MODEL METHOD AND DATA

Figure 1 illustrates how KC score is transmitted via economic resilience in income and job growth or contraction.

Figure 1 KC domains and transmission to indicators of economic resilience



The investigation compiled data from several sources to determine post-GFC resilience. There were some obvious limitations. First, KC index scoring is problematic (Høyland *et al.* 2011). Second, corresponding data was not available across some cities which distorted the sample frame, See Table 1.

STATISTICAL ISSUES

Any spatial rendering of 'KC' analysis confronts statistical issues, the most pertinent of which are:

- Sample frames
- Spatial resolution
- Access definitions

Ideally, KC analysis should proceed based on stratified random sample to reduce costs without compromising variability (Clifford 2011). Some KC studies present lists of cities for which statistics are readily available without randomised selection from a rationally constructed sample frame. Boundary specifications in many studies are

 ISBN: 978-1-84219-840-7 .

vague. Spatial resolution is also a significant problem since many 'KC' indicators are collected at the national level. Oftentimes, reliable price data is unavailable. Hence, a limitation for the study was the use of intermediate urban economic growth to get insight into likely office investment performance. A more robust future study should randomly select buildings from the randomly generated cities under investigation and collect longitudinal property level data on total risk-adjusted returns. Finally, often KC studies are woefully deficient with respect to concrete indicators of local urban form conviviality on the ground. In this regard, access to useful facilities or distance from hazards and nuisances should be modelled on network linkages not Euclidean distance (Nair 2011).

FINDINGS: ALTERNATE DRIVER: MIDDLE CLASS DEMOGRAPHICS

Statistical limitations notwithstanding, the results suggest a link between KC, as indicated by CityCard 2010 score, post-GFC income resilience as illustrated in Figures 2 and 3 below. While Figure 3 suggests that KC confers no economic resilience, nearest-neighbour analysis, in Figure 3, unmasks the confounding effect of fast middle class growth in some developing countries to reveal KC resilience contribution. The nearest-neighbour statistic, R, is 'the degree to which an observation departs from an expected random pattern' (Rossbacher (1986: 1). R suggests that post-GFC economic resilience is linked to KC but in two separate sub-markets: established (low risk sovereign) cities and emerging (higher risk) cities with rapidly expanding consumer classes.

Figure 2 Apparent lack of relationship between KC index and post-GFC resilience.

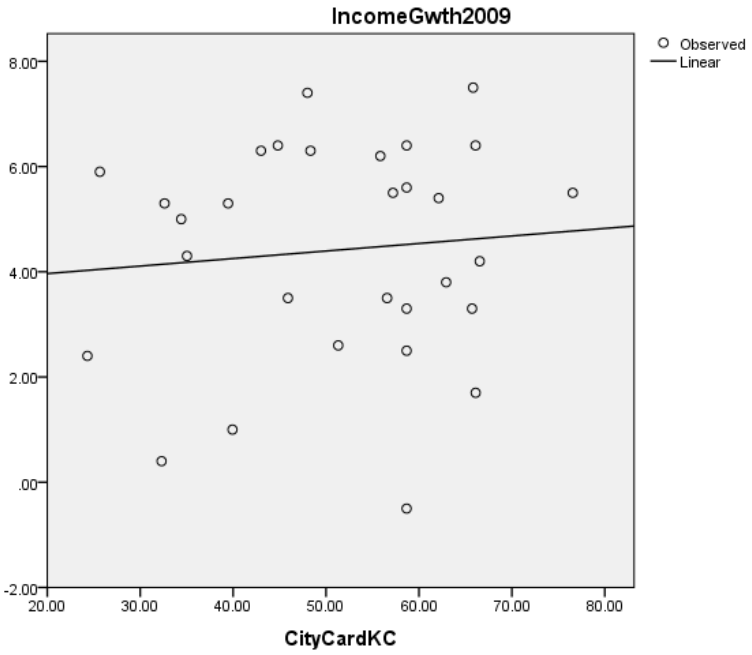

Figure 3 Nearest neighbour analysis, disentangles the confounding KC and population growth drivers.

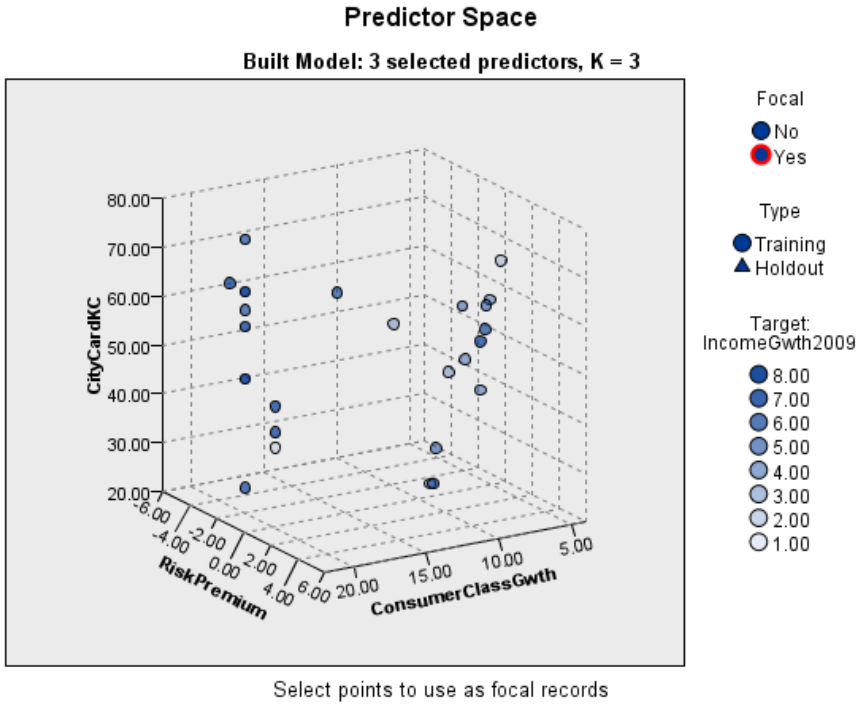

CONCLUSION

Our preliminary investigation into the knowledge city concept finds it conflicted with antecedents in regional development. In the urban regeneration stakes, the knowledge city vies for popularity with other new economy contenders, including the 'creative city'. Notwithstanding conceptual ambiguity and significant statistical concerns, our preliminary investigation found it confers post-GFC resilience but no more than burgeoning middle-income populations. The implication for investors is that direct property portfolios should be diversified both across KC and high middle class population growth cities. City authorities, seeking to lure private investment should consider an appropriate KC marketing campaign in conjunction with concrete measures to improve public transport logistics, aesthetics, pedestrianisation and coherent place-making. In short, despite some definition ambiguity, the KC concept remains relevant. Particularly attractive locations for investors are KCs with a rapidly expanding middle class.
