Total	**15 hrs**

The overall goal is to allow the Auburn student to graduate on time even though they had the opportunity to study a full semester in a totally different culture and environment.

CONCLUSIONS

The overall goal of every BSCI faculty-led study abroad class is to *expose* students to companies, projects, materials, methods, equipment, and construction professionals that they would never be exposed to otherwise. Another major goal of every class is

to *expand* the students' academic, professional, and personal views of the world from regional to global.

The Building Science faculty is firmly convinced that study abroad courses add tremendous value to the educational experience of not only the students who participate, but to our entire construction management program in general. Interaction with the participating students after they return to Auburn stimulates even more interest among lower-level students and faculty members each time. Prospective students and their parents often ask about the details of the study abroad classes when making campus visits. The success of our study abroad classes gives our students a real-world global perspective that would be hard to obtain otherwise.

LEGAL TOPICS IN THE BACCALAUREATE DEGREE

Jodi J. Farrington, PhD PE[1] and Syed M. Ahmed, PhD[2]

[1]*Department of Construction Management, East Carolina University, 343C Rawl, Greenville, NC 27858, USA*

ABSTRACT

A review of descriptions of legal and contract courses offered by ASC member and ACCE accredited CM baccalaureate programs was performed. Overall, the course descriptions were found to fall short of demonstrating compliance with ACCE accreditation requirements. Potential explanations for this deficit include course descriptions written in general terms and actual non-compliance with the ACCE requirements. While Construction Law and Contracts were covered by nearly one half of the programs reviewed, more than 80% of the programs failed to display compliance with the remaining legal requirements. The dominant conclusion of this study is the need for the decision makers of the construction industry, institutions of higher learning, and accreditation bureaus to work together not only in development of strong CM programs but also clear indications of topics included in the curricula.

Keywords: accreditation, baccalaureate, contract, law, legal.

INTRODUCTION

New graduates with a baccalaureate degree in Construction Management are expected to be able to manage the day to day activities of a construction project often with the responsibility and authority of a Project Manager. Throughout their college career these graduates studied topics including Planning and Scheduling, Estimating, Materials and Equipment, Soils, MEP and a plethora of other topics. Many schools also include a requirement for students to take a class or two in Business Management where contract theory, negotiation, and ethical behavior are discussed. With this all-around exposure to topics and concepts the students, now graduates are presumed to be ready for an assignment in Project Management. However, observation of the graduates' on the job performance too often reveals an apparent lack of readiness. The survey performed as the basis of this paper supports that observation and indicates that the students have not received the necessary training required to fulfill these expectations, particularly with respect to legal topics.

[1] farringtonj@ecu.edu
[2] ahmeds@ecu.edu

The intent of this study was to make a preliminary determination of the clearly covered topics included in the curriculum of the baccalaureate degree in Construction Management. Of specific interest are those topics associated with construction law. Given that the number of Construction Management programs available in this country alone is quite numerous some selection filters were applied. Specifically, to be included in this review a CM program was considered only at the Baccalaureate level, must have been accredited by the American Council for Construction Education (ACCE), and must be a member of the Associated Schools of Construction (ASC).

ACCE accreditation was deemed necessary as those are the requirements against which each program was to be characterized. Additionally, membership in ASC was set as a criterion by presuming that a program with ASC membership would take seriously the need to fully educate its students. It should be noted that these selection filters excluded programs that are ABET accredited rather than ACCE. The omission of these programs should not be taken as an indication of deemed lesser qualifications rather simply that we desired an initial study pool of controlled size. After sorting the rosters of associated programs in both groups a total of 63 programs were identified for review.

ACCE accreditation requirements

The ACCE document entitled *Standards and Accreditation of Postsecondary Construction Education Degree Programs* published in 2011 was found on the ACCE webpage at www.acce-hq.org Review of this document showed the subject matter items listed below are required to be offered by a CM program to receive accreditation by ACCE.

- Oral and Written Communication
- Physical Science and Mathematics
- Economics, Principles of Management, Accounting, and Business Law
- Design Theory, Construction Systems, Construction Methods and Materials, Construction Graphics, and Construction Surveying
- Estimating, Planning and Scheduling, Construction Accounting and Finance, Construction Law, Safety, and Project Management

The ACCE document also provided greater detail of requirements for certain fields. The detail requirements included under Construction Law, and thus, the topic of this study, are:

- Construction Contracts, Roles & Responsibilities of Parties
- The Regulatory Environment and Licensing
- Lien Laws and the Contractor's Rights
- National and Local Labor Law
- Administrative procedures to Avoid Disputes

The plan for implementation of the survey was to review the website for each of the 63 selected programs and identify how many of the programs met each of the criteria.

Course descriptions vs. requirements

The curriculum of each program was reviewed for required class titles that appeared to include any or all of the topics on the list. Then, the descriptions of these courses were entered into a spreadsheet for detailed review. The detailed information was far

easier to find on some websites than others and ultimately there were 19 programs for which no course descriptions could be found.

The data collected from the website of each program was used to gauge conformance with the ACCE requirements; no comparisons or ranking of programs was made and no challenge of the ACCE accreditation should be inferred.

Table 1 lists the ACCE requirements and the number of programs that indicated conformance based upon a word search of the course descriptions.

Table 1

ACCE Topic	**No. of Programs***
Construction Law	19
Construction Contracts	20
Roles & Responsibilities	8
Regulatory Environment & Licensing	3
Lien Laws & Contractor's Rights	7
National and Local Labor Law	5
Administrative Procedures to Avoid Disputes	16

**No Course Descriptions were found for 19 of 63 programs*

Even though no information could be found for course descriptions in 19 of the 63 programs it was anticipated that the search results for each area would have been closer to the 44 identified programs with information available.

In anticipation that the text of the description conveyed intent of class coverage without using the exact words stated by ACCE each course description was independently reviewed and counted against each topic in accordance with the understood intent of the course. The results of the revised count are shown in Table 2.

Table 2

ACCE Topic	**No. of Programs**
Construction Law	27
Construction Contracts	28
Roles & Responsibilities	17
Regulatory Environment & Licensing	4
Lien Laws & Contractor's Rights	8
National and Local Labor Law	5
Administrative Procedures to Avoid Disputes	24

Although the results of the revised review were improved, they still fell far short of anticipated findings. The findings regarding the first three listed topics, considered vital for the success of the construction industry, are discussed in the following section.

Discussion of findings

The topics of Construction Law, Construction Contracts, and Administrative Procedures offer the best correlation with the terms included in the ACCE requirements. This should come as no surprise given the nearly daily requirement for

a PM to refer to the contract, plans, and/or specifications to resolve some question at hand. What may be surprising is the apparent lack of total compliance. For the most part, this shortage is a result of a classification decision used in the study. Many CM programs seem to partner with Business School classes for the coverage of Contract Law. Programs that did so were not given credit for compliance with this item. The basis for this choice is the difference between construction management and business management. While contracts in both arenas certainly have the same basics such as agreement, offer/counter-offer, and consideration, construction contracts also include numerous additional topics including schedule, unit pricing, change procedures and retention. Since a qualified PM must understand all of these topics, and more, compliance credit was given only for courses specifically covering Construction law, contracts, and administrative procedures.

Compliance in the area of Roles and Responsibilities is surprisingly low; particularly when one considers the number of different players involved in a construction project and the varying levels of authority of personnel representing the involved companies. Imagine the new PM going out to the project site believing that it is his job to assure that all the work is being performed properly. In its simplest interpretation certainly not a difficult task to understand. Now imagine that same PM while viewing the progress runs across a junior member of the design team who is in the field to measure work completed. The two begin to talk and the junior designer mentions that the sidewalks the contractor is setting formwork for should be 5' wide not 4' as they are currently doing. Of course our PM checks his plans and sees that they call for 4' wide sidewalk but, not having studied roles and responsibilities in school, believes it to be his duty to follow the intent of the designer and instruct the contractor to revise the width of the sidewalks. Innocent mistakes, even made with the best of intentions, are still costly.

The survey shows an amazingly poor compliance in the areas of Regulatory Environment, Licensing, Lien Laws, Contractor's Rights, and Labor Laws. Many CM programs cover these topics but only at the graduate level so those results were not included in this count. It may be argued that these topics vary by State and thus too broad too cover. However, the basics remain the same and in accordance with the ACCE requirements should be covered.

CONCLUSIONS & RECOMMENDATIONS

ACCE requirements for accreditation of a baccalaureate program in Construction Management are quite clear and comprehensive. Questions arise however, when the course descriptions at different learning institutions are reviewed. While the institution may have ACCE accreditation, compliance with the requirements is not always readily apparent. Now, while the programs are growing and evolving, is the time for industry, schools, and accreditation bureaus to work together to develop the strongest possible programs and generate clear descriptions of topics included.

Having reviewed the results of the survey and considered some of the potential risks in not covering the identified topics some recommendations for improved compliance and performance may be made.

With all of the discussion presented thus far, one obvious point has not been mentioned: that course descriptions may be written in a general fashion and do not

specify each topic included within the course. ACCE has stipulated topics that must be included in a curriculum for that program of study to become accredited. The average member of the construction industry probably does not know the ACCE requirements for accreditation by rote. Course descriptions need to be specific about the concepts included. This would not only give the potential student a better idea of what they will be studying but will also let industry know the specific topics covered in the program.

Some of the concepts included in discussions of law, regulation, and contracts are deeper and more involved than those generally found at the undergraduate level. Perhaps it would be of benefit to industry, CM programs, ACCE, and students to revisit these requirements. To be effective, a PM must certainly understand the basic concepts of construction law and contracts; conceivably, decision makers in the construction industry could provide input to ACCE regarding their priorities of needs and expectations of a CM education in general and specifically legal aspects.

Degree programs in Construction Management are still relatively new. Many colleges and universities are still struggling to decide where best to house the CM program. While it is certainly difficult going through the growth and development of the programs now is an opportune time to make enhancements to the curricula. One such modification might be to require students to work in the field for a stipulated period of time. Whether a sponsored internship or simple summer job the field exposure would offer the student not only confirmation of lessons learned but also the importance of the required legal concepts. Of course there are countless opportunities to enhance a CM curriculum but the changes need to be made in a controlled manner to assure continuity of the requirements.

Finally, this study did not consider ABET accredited CM programs; however, such a study would certainly be beneficial. The construction industry as a whole needs assurance that a graduate with a baccalaureate degree in Construction Management has the same basic knowledge regardless of the school of study. ABET and ACCE accreditation requirements should be reviewed and compared; perhaps melding the two would result in the ultimate CM program.

NON-PAYMENT BY EMPLOYERS TO SMALL AND MEDIUM CONTRACTORS: CONTRACTUAL REMEDIES

Ramabodu,M.S.[1]

[1]*Department of Quantity Surveying and Construction Management, University of the Free State, Bloemfontein, South Africa*

ABSTRACT

The effects of late or non-payments have been felt more particularly by small and medium-sized contractors and consultants, causing these contractors and consultants severe cash flow problems and affecting their performance negatively. When faced with a situation of late or non-payment, the only reaction or remedy is to consider stopping the work on site. From a South African perspective, a recent case study proposes some remedies which contractors may use when confronted with late or non-payment. The findings of this study will assist the small and medium-sized contractors to understand their position before they can take any action when employers fail to make payment or effect late payment to contractors. The rights and obligations of the contracting parties are therefore examined and solutions will be proposed.

Keywords: Non-payments, employers, building industry, contractors.

INTRODUCTION

The sustainable development in the construction industry is one of the prerequisites for the sustainable development of the South African economy as a whole. If the construction industry becomes uncompetitive, it will make all private investment in capital assets unattractive. It will also restrict improvements in general infrastructure. The industry remains a major source of employment creation and is therefore both a means and a method of facilitating development.

> "*Poor payment practices in the construction industry give rise to substantial additional financing and transaction costs. More importantly, certainty over how much and when payment is made builds trust between supply team members and underpins collaborative working to achieve value for money projects for clients."*

In a stable environment, a construction business requires very limited permanent capital to start or operate. Construction projects are largely financed through interim or monthly payments that fund the next stage or period of work. Capital requirements are restricted to the spread in cash flow between payments and receipts.

[1] ramabodums@ufs.ac.za

According to Buys (2006), the biggest problem faced by the construction industry in South Africa is the problem of late payments by clients and this situation leads to disputes that end up being treated as routine maintenance.

WHAT DOES PAYMENT MEAN

Payment means the money given or to be given to a person in return for the goods sold or services rendered. In construction, payment is defined as "a monetary consideration for the contractor's performance or work done" (Judi & Rashid, 2010). In *Royden (M) Sdn Bhd v Pembenaan Yeah Tiong Lay Sdn Bhd*, payment was defined as "the value of any work, materials or goods comprised in the contract.". In other words, payment is the consideration, in terms of money, for the work that a contractor has carried out in accordance with the contract plus the materials delivered to site. Contractually, the said money must be paid promptly and fully unless there are specific reasons for delaying or withholding it (Judi & Rashid, 2010).

In the past a number of different authors examined the problems related to non/late payments to contractors both in South Africa and abroad.

REFERENCE TO THE MARX REPORT (2009) AN OVERVIEW

The Marx report indicated that, in payment delays experienced by contractors for the years 2004 to 2007, there was a decrease from 24% to 9% in the number of all projects where payments were made timely within 14 days, if the 2004 results are compared with the 2007 results. In 2007 the private sector clients were the worst early payers, with payments made within 30 days on only 35% of their projects. Public private partnerships were the best performing clients with 59% and 56% respectively. There was an increase in projects with payment that took more than 30 days from 43% in 2004 to 56% in 2007. At least there was a reduction in percentage that was 120 days by 13% in 2004 to 3% in 2007 (Marx, 2009; Maritz & Robertson, 2010).

REFERENCE TO THE MASTER BUILDERS SOUTH AFRICA DRAFT REPORT 2009

In response to the Marx report, master builders have conducted their own research and their findings were summarised as follows:

Nationally, across all clients, (all projects included in the survey), 54% of projects were paid within 30 days; 26% between 31 and 60 days; 13% between 61-90 days; 3% between 91 and 120 days and 4% more than 120 days.

National government and the private sector seem to have the best record with 85% and 79% of payments made within 30 days and the 15% of national government was paid between 31 and 60 days (Maritz & Robertson, 2010).

Local and provincial government payments were only effected between 31 and 60 days after invoicing (45% and 44% respectively) with only 38% and 23% payments made within 30 days from date of invoice and 15% of local government projects paid between 90 and 120 days after date of invoice.

In South Africa specifically the *Public Finance Management Act*, Act 1 of 1999 stipulates that payment should be made within 30 days of submission of a valid claim. It appears that many employers do not comply with this legislation or the terms of contracts signed between the parties.

THE CONSTRUCTION INDUSTRY DEVELOPMENT BOARD INDICATORS

The Construction Industry Development Board (2009) publication was summarised as follows: In the survey related to contractor payments, completed in 2009, it was revealed that 42% of payments were made within 30 days of submission of a claim; 48% was paid between 30 and 90 days; and 9% was paid after 90 days. It was also recorded that 47% of clients' agents were paid within 30 days after submitting a valid invoice, whereas 46% were only paid between 30 and 90 days; 7% were paid over 90 days. Refer to Table 1 below for outstanding fees for more than 90 days.

Income distribution	**Jan-Jun 2007**	**July-Dec 2007**	**Jan-Jun 2008**	**July-Dec 2008**	**Jan-Jun 2009**	**Fee income outstanding longer than 90 days R million, current price**
Central Government	4.8	10.4	5.3	3.9	7.3	R53
Provincial Government	5.7	5.4	5.8	4.3	3.8	R132
Local Government	6.9	8.3	10.5	6.9	13.2	R419

Source: cidb, 2010 practice notes

Hasmori MF, Ismail I & Said I. 2012. "Issues of late and Non-payment among contractors in Malaysia"

According to Hasmori, Isamail and Said (2012) the major factor leading to a successful project is the practice of efficient and timely payment in construction projects. In their study the following were extracted and summarised as follows:

There are numerous factors that cause late or non-payment and the majority of them involve clients, developers, contractors and contractual matters. Reeves (2003) as cited in Hasmori, *et al.*, (2012) states that the main reasons for late payment are errors that occur in submitting claims. This includes claims without adequate supporting documents, incorrectly calculated claims and those submitted without following the right procedure. Some other important reasons indicated in this study were contractors failing to agree with the valuation of work on site; payment being wrongfully withheld by clients or client representatives (Ismail & Said, 2012). According to Rahman, Wang, Takim and Wong (2011), late payments are defined as failure by a paymaster to pay within the period stipulated in the schedule of contract. Furthermore, they argue that cash flow management is to avoid extended cash shortages as a result of having too great gaps between cash inflows and outflows.

 ISBN: 978-1-84219-840-7 .

CONTRACTUAL REMEDIES

Suspension Of Work

According to Judi and Rashid (2010), a contractor is entitled to suspend the works on site following any late or non-payment if such a term is expressly stated in the contract. But when one examines the general principles of common law, the contractor has no legal right to suspend the work; nor does the employer have a legal right to order its suspension. Once the contract work has commenced, it is the contractor's obligation to carry out the work in a regular and diligently manner until it is completed. As a result, unjustified suspension by either party will amount to a breach of contract for which damages may be claimed. However, in common law a contractor has a right to suspend work as long as the damage is not sufficiently serious to become a fundamental breach. In the United Kingdom, section 112 of the *Housing Grant Construction Regeneration Act* (HGCRA) provides that when the sum is not paid on the final day of payment and no withholding notice has been issued by the employer, then the contractor is entitled to suspend his performance until the full payment is settled.

Slowing Down The Works

Furthermore, Judy, *et al*. (2010), indicates that in the Malaysian construction industry the contractor has no legal right to slow down the works for reasons of late or non-payment, unless of course it is clearly stipulated in the contract.

Claim For Interest On Late Payments

In the South African context, the JOINT BUILDING CONTRACT COMMITTEE (JBCC) principle agreement clause 31.11, where the contractor does not receive payment of the amount due by the due date, the employer shall be liable for default interest on the amount without prejudice to any other rights the contractor may have. Such interest amount shall be compounded monthly from due date for payment up to and including the date on which the contractor is to receive payment and included in the recovery statement. The principle agent shall calculate such default interest at the rate of one hundred and sixty per cent (160%) of the interest. Mvubu and Thwala (2008) in their study argues that contractor must have a credit relationship with suppliers but, if they receive their payments late, this relationship will be destroyed and the supplier will charge interest from the contractor which he did not receive from the client.

Termination Of Contract

For most construction contracts, payment within the contractually agreed framework is not specified to be "of the essence" and therefore a failure to make payment would not be a breach that goes to the root of the contract. Under the law of contract, failure to pay on time what is due will not be treated as a sufficient breach to justify the other party's terminating the contract.

METHODOLOGY

A post-positivist paradigm was applied to evaluate the effects of late or non-payment by clients to contractors and consultants in the building industry. 31 questionnaires were hand delivered to industry professionals and consultants around the Free State Province of South Africa. Twenty responses were recorded, meaning a 65% response rate. This sampling was purposely selected among industry professionals and

contractors and this sampling comprises 10 quantity surveyors, 2 engineers, 2 contractors, 3 architects and 3 project managers. There were 14 questions in the survey and the respondents were requested to present their opinion on a Yes or No scale, whereas for other questions a 5-point Likert scale was adopted where 1=Never, 2=Sometimes, 3=Rarely, 4=Often and 5=Always.

RESULTS AND DISCUSSION

Table 2 represents the opinion of the respondents in terms of questions 1 to 10. This clearly indicates that 60% of the respondents agree with the statement that they did in fact have claims that were delayed as a result of lacking adequate supporting documents. In question 2, 75% of the respondents also agreed that they have had claims that were returned as a result of errors in the claim. In question 3, 50% confirmed they have had delays as a result of claims that were incorrectly calculated and 50% also said No on the same question. Regarding question 4, the respondents answered in the same manner as in question 3 where 50% of them agreed that they experienced delays as a result of a contractor failing to agree with the valuation of the work on site; 50% disagreed. In questions 5, 85% of the respondents were in agreement with the fact that they have experienced delays as a result of clients or client representatives wrongfully withholding their payment. In question 6, 60% of the respondents indicated that they do have some cash reserves to operate their business while their payments are delayed. In question 7, 65% of the respondents agreed that they rely on credit to finance their projects whenever they experience any delays in payment. In question 8, 75% of the respondents agreed that there should be legislation to regulate late or non-payment. For question 9, 100% of the respondents agreed that late payment affects their cash flow. In question 10, 60% of the respondents agreed they have suspended work in the past as a result of late or non-payment.

	Question	**Yes**	**No**
1	Was your claim ever delayed as a result of lacking adequate supporting documents?	60%	40%
2	Did you ever have a claim returned as a result of an error in the claim?	75%	25%
3	Delayed as a result of an incorrectly calculated claim?	50%	50%
4	Delayed as a result of contractor failing to agree with the valuation of the work on site?	50%	50%
5	Delayed as a result of client/client's representative wrongfully holding the claim?	85%	15%
6	Do you have cash reserves to help your business operate when payment delays are experienced?	60%	40%
7	Do you rely on credit to finance your projects?	65%	35%
8	Should there be legislation that regulates non or late payments?	75%	25%
9	Do late payments affect your cash flow?	100%	0%
10	Have you ever suspended work as a result of non/late payments?	60%	40%

Table 2: Summary of trends indicated by the survey

In question 11 in Table 3 below, 45% of the respondents said they have never charged interest on late payments even though this was addressed in the JBCC contract. Only 15% of the respondents indicated that they always charge interest on late payments.

To question 11, 30% of respondents said they always insist on clients providing a payment guarantee on their projects, whereas 20% said they never ask for a payment guarantee; 20% said they sometimes require a payment guarantee and 10% responded with Rarely.

	Question	**Never**	**Sometimes**	**Rarely**	**Often**	**Always**
11	How often do you charge interest on late payments?	45%	15%	25%	0%	15%
12	How often does your company insist on the provision of a payment guarantee?	20%	20%	10%	20%	30%

Table 3: Summary of the trends indicated by the survey

Regarding Table 4 below, 45% of the respondents said they would like to receive payment 14 days after invoicing, while 15% of the respondents said they would be comfortable even if they received payment 21 days after invoicing; 25% of the respondents indicated that 30 days after invoicing should be all right to receive payment and none of the respondents wanted to be paid after 60 days.

	Question	**14 days**	**21 days**	**30 days**	**60 days**
13	What period would you prefer to be paid?	45%	15%	25%	0%

Table 4: Summary of the trends indicated by the survey

CONCLUSION

It is evident from literature that this problem of late or non-payment is not new. Based on various literatures it can thus be concluded that:

The problem of late or non-payment is not improving when compared to previous surveys. More money in terms of fees outstanding for over 90 days is lost which could have helped in growing the economy from a South African market perspective. The rule to suspend work does not help the situation, however, slowing down the work does not relieve the contractor or consultants from the problem of cash flow and contractors and consultants must re-examine their positions from a common law perspective before entering into any contract with any clients. Legislation on non-payment must definitely be introduced in South Africa to address the problem of late or non-payment and more consultants and contractors must charge interest on late payments.

RECOMMENDATIONS

The following are recommended:

- That in the contract data, payment duration should be stipulated and agreed upon;
- Payment legislation must be adopted in South Africa;
- It should be made compulsory for government clients to produce a payment guarantee before any project can commence in South Africa;
- There should be a performance incentive for any government departments that pay on time, e.g. a bigger budget allocation on the following financial year's budget; and
- Compulsory interest on late or non-payments by government departments; the departmental head of that specific department must be accountable for late or non-payments.

ABSTRACT

The need for increased time and geographical flexibility; fluctuations in the economy; increases in the cost of study; fast paced lifestyles; increased technological competence and job market demands for employees to gain new skill sets and professional and academic credentials means that employees are increasingly under pressure to make judgements in relation to choice and method of academic study and are concerned about how these choices will impact on future employability and translation into jobs or careers. Employers seek study options that provide value for money, address skill gaps, are flexible and have minimal disruptive impact on business operation and productivity. The research explored construction industry employer perceptions in relation to the educational needs of construction employees, in particular, types of qualifications employers want employees to have in future, traditional versus fast track degrees and attitudes towards the development of a general degree in construction. The study found professionally accredited qualifications and continuing professional education (CPD) to be high priority for employers, skills training and academic/professional qualifications to be viewed as of equal importance and the three year degree to be considered still relevant in the current job market.

Key words: Construction, Employer, Educational, Needs, Perceptions.

INTRODUCTION

The research was undertaken in the Professional Academy (PA) in the Faculty of Advanced Technology (FAT) at the University of Glamorgan. The Professional Academy is a European Social Fund (ESF) funded project, with a value to £2.3m. The PA provides a variety of work based learning (WBL) solutions to the Welsh workforce. The project aims to engage with companies in a variety of sectors including the energy and environmental management sectors in addition to automotive, aerospace and construction sectors to up-skill employees through flexible bite sized learning opportunities. Graduate employment is being adversely affected by the current economic climate (CBI 2009). It is

[1] ejones4@glam.ac.uk

[4] slthomas@glam.ac.uk

with the depressed labour market and policy steers from (Leitch 2006), (Welsh Assembly Government 2002, 2005, 2008 and 2009) and the (RICS 2009a) Consultation Document on employability in mind that has led to the Professional Academy offering academic support and guidance to both employers and employees looking to engage in work based learning solutions. The PA wanted to engage with employers to explore training needs and develop new ways of developing and delivering courses that were attuned to market trends and needs, and be attractive and innovative enough to convince employers to release employees to engage with short term learning.

BACKGROUND

Policy Initiatives – National and Welsh Assembly Government

The need for universities to engage with industry has increased dramatically in recent years. (Lambert 2003) identified collaboration and partnership as key factors to achieving success in producing more industry aware/relevant graduates and higher level research and development (R & D) within industry. The (Leitch Report 2006) and three Welsh Assembly Government (Welsh Assembly Government 2005, 2008 and 2009) policy initiatives, the "Learning Country Vision into Action", 'Skills that Work for Wales' and 'For Our Future' suggest it is now timely and in line with government policy, both national and Welsh, to enrich the higher education curriculum with greater awareness of the value of work based skills and learning through work. One of the main recommendations of the (Leitch Report 2006) is to increase an individual's aspirations and awareness of the value of skills and to raise the profile of vocational education. This driver is echoed in the Welsh policy 'Skills that Work for Wales' (WAG 2008) document.

The 'Learning Country – Vision into Action' (WAG 2005) stresses the need for informal and work based learning to become a recognised and accredited part of the curriculum. This emphasis on work placement as part of the curriculum and the importance of graduate employability were reiterated in the 'For Our Future' (WAG 2009) policy. In response to the Government's 2003 Higher Education White Paper HEFCE gave development funding from 2005 to 2010 to eight higher education institutions to pilot forms of flexible provision. These institutions, the Flexible Learning Pathfinders, piloted a range of provision which included two-year accelerated Honours degrees, delivered via a variety of flexible learning methods. The final report recommends actions that could be taken in order to support the development of flexible learning in particular, provision of better information for prospective students about availability of flexibly delivered courses and alternative study options; basing fees on credits delivered rather than years of study; changes to institutional structures and systems to support flexible delivery and demonstrating that accelerated degrees deliver similar outcomes to conventional degrees.

Economic

The UK economic downturn continues with overall employment in construction about 59,000 fewer in 2012 Q1 than a year earlier (Green 2012). Recent research has shown the impacts of the recession on the employment prospects of all property and construction graduates and speculated that the ongoing cuts in public expenditure on construction and infrastructure projects will continue to make the job market for graduates difficult in the foreseeable future (Devaney and Roberts 2012). The gloomy economic outlook combined with the recent requirements from RICS relating to the development of graduates' employability skills and greater employer/industry engagement encouraged the Professional Academy to develop a project that would enhance graduate employability through propagating a positive culture of professionalism.

Academic

In studying the alignment of professional, academic and industrial needs for Quantity Surveyors in a post recession climate, (RICS 2011) highlighted how the professional and training needs of Quantity Surveyors are pulled by three different stakeholders (academia, professional body and industry) in three different directions. The academic focus is on producing graduates with a basic foundation in knowledge for further development, professional bodies are interested in graduates who can be progressed to full professional status through the achievement of the required core competencies (RICS, 2009b) whilst industry is looking for graduates who can immediately contribute to the daily functions of business activity and its growth. This tripartite three dimensional pull on development needs in the present education system produces graduates whom the industry sees as not fulfilling their requirements, leading to many problems, with greater levels of employer and graduate dissatisfaction and obstacles to early career development of the QS graduate.

RESEARCH METHODOLOGY

The research reported in this paper was conducted in late 2011/ early 2012 and forms part of a wider study, which was conducted with employers and employees in the construction industry in order to learn about their work based and e-learning needs and to inform future course design and educational delivery. In particular the research focussed on the types of qualifications and courses employers and employees are interested in studying in future. This included professional accreditation and continuing professional development (CPD), employer and employee attitudes towards traditional degree courses, the importance of gaining academic and professional qualifications versus relevant skills training, preferred method and mode of course delivery, and suggestions for the development of content and exploration of value and applicability of a general degree in construction.

The study relates directly to the aim of the (ESF) Professional Academy Project which aims to transform the way that the Faculty of Advanced Technology traditionally delivers modules by allowing employees to study directly from the workplace in a variety of ways, including innovative live streaming of lectures**,** online distance learning materials and also bespoke training where businesses can directly access the expertise of academic staff in order to address skill gaps.

Semi structured interviews were conducted with 43 employers (in 29 companies) and 24 employees from those companies in the construction industry who were being supported by the Professional Academy. The duration of the interviews ranged from 20 to 45 minutes. Interviewees included a range of: Housing Associations; large national/multi national construction contractors; small to medium sized enterprises (SMEs); local authorities; building consultancies and Construction Skills Wales. The organisations were categorised for analysis as follows: Consultant (n=10), Education Provider (n=3), Contractor (n=17), Housing Association (n=11), and Local Government (n=2).

The interview questionnaire was mainly qualitative in nature and consisted of open ended and multiple choice questions, with accompanying follow up probe questions (to more fully explore the views of employers). The interviews were conducted by telephone and the researcher took detailed notes in relation to each question. The notes were then transcribed and the data was coded in relation to each respondent answer for each question. The data was analysed using the qualitative method of content analysis in order to discover the regularities occurring in the interview discourse, identify and categorise

answers and establish connections between them (Holsti 1969; Riley 1990). In order to provide the quantitative data for the analysis, the answers to the multiple choice responses were frequency counted.

RESULTS

Entry to employment - required future qualifications

Employers indicated a broad variety of qualifications that they required employees to have on entry to employment. Almost half of those interviewed specified the need for employees to have a relevant degree, e.g., Quantity Surveying, Civil Engineering, Project Management, Mechanical Engineering on entry into their field of occupation. Only four employers indicated that degree level qualifications were less important for entry (unless applying for a specialist job) and that employee qualifications on entry ranged from NVQs, HNCs, HNDs to degree level. Employees were expected, and/ or encouraged to progress educationally after becoming employed.

Small to Medium Sized Enterprises (SMEs) and Housing Associations indicated if they required specialists in particular fields it was more cost effective for them to hire specialist consultants. A small number of employers (in large national/multi-national consultancy/ contractor organisations) indicated that study involving a regular time commitment as day release from work can act as a distraction (especially if employees are required to take 2-3 days off per week). They felt employees were less committed to their regular job (through the need to focus on study) and were disadvantaged in job placements and project allocation when compared with other full time staff, as they are less available and have reduced flexibility.

Professional Accreditation

Almost all of the employers who were interviewed indicated the importance of chartership status within a chosen field, e.g., RICS, CIOB, ICE and RIBA. RICS and CIOB appeared to be the most commonly occurring accredited professional qualifications indicated by the employers who were interviewed; however this may have been skewed in this direction because the employers were from the construction industry, where there is a heavy representation of RICS and CIOB. Employees were encouraged to pursue chartership, either through obtaining an accredited degree, Assessment of Professional Competence (APC), external top up courses, or in-house training. Chartership was viewed as the most important educational aspiration for employees for two reasons: firstly, it provided value to the employee as a recognised professional qualification which would benefit the employee long term. Secondly, it made the company/organisation more competitive in the market when bidding for work, as client confidence was based on perceptions of team competence and professionalism, which could be validated by demonstration of professional qualifications and membership of professional associations and bodies.

Continuing Education

Employers highlighted the value of short, modular courses in subjects such as, project management, health & safety, sustainability, environmental issues, waste management, and carbon management. In addition, they expressed an interest in ‘soft skills’ courses in staff management, and leadership skills. Short courses were attractive to employers as it boosted CPD whilst at the same time taking employees out of the work situation for shorter periods of time, enabling companies to remain competitive in the market in this difficult financial climate. Few employers indicated that they wanted employees to progress onto Masters level qualifications and did not feel that this type of qualification

 ISBN: 978-1-84219-840-7 .

was relevant to them. One contractor indicated that a moratorium had been placed on Masters courses for employees unless there was a very good business case to indicate value and benefit for the company for that type of qualification. Overall employers felt that skills training and experience were equally as important as professional and academic qualifications. Academic and professional qualifications were felt to be important for potential employees to get to the interview stage of recruitment however, the ability to demonstrate skill and experience at interview and the ability to perform well in the role was felt to be more important post recruitment.

Employer opinions of a 3 year and 2 year degree course

Opinion was divided almost equally amongst employers in relation to a three year degree being an outdated concept. Twelve employers (28%) were unsure if a three year degree was an outdated concept and did not feel qualified to comment, sixteen (37%) felt that there was merit in preserving a three year degree and fifteen (35%) felt that there was merit in shortening, or fast tracking the three year degree. Twenty five out of forty three (58%) employers said that they would value a shortened degree as they felt it would provide a more attractive option to mature/older learners, potentially lower student drop-out rates and offer a solution to allow people to enter the job market more quickly which they felt was particularly important in the current economic climate with the potential negative impact of increases in university fees. However, despite advocating a shortened degree in the current financial climate, employers provided a caveat that the depth and breadth of the content would need to be preserved and quality assured in a more intensely delivered degree programme (to ensure that the qualification was not perceived as devalued).

Attitudes in relation to the development of a General Degree in Construction

Employers were supportive of the concept of introducing a general degree. Thirty out of forty three employers (70%) felt that it was a good idea, as opposed to ten who did not. Those who were supportive of the idea felt it provides a broader base in choice of career, a wider range of skills and does not pigeon hole people too early in their choice of career. A generic qualification in construction was felt to be good for smaller organisations who could not afford to engage a team of specialists. Employers who were unsure (7%) or who thought a general degree was a bad idea (23%) did so because they felt that specialist roles within companies require specialist degrees and that the area of construction is too broad to allow teaching modules to cover any significant depth that would prove useful to employers. Deciding upon the content of a proposed general degree proved difficult for employers as the range and variety is very broad. Employers had differing needs and priorities of what it would be important to include. They felt that it is important to reflect current trends within the construction market whilst at the same time providing a broad grounding across the subject area. Perhaps this and the mandatory competencies requirements account to some extent for 6 out of 500+ RICS awards being general (3 of which are in the Far East).

DISCUSSION

Academic/ Professional Qualifications and Training

It was significant the half of the employers still felt that a degree was necessary as an entry level qualification for employees. Although employment of graduates with specialist qualifications was favoured in contractor/consultancy organisations, local government and Housing Associations favoured generalists and stated they would prefer to sub contract specialists as overall this was more cost effective. A small number of employers in the

larger companies indicated that although they support employee education and continuing professional development, time commitments for study can have a negative impact upon employee flexibility and the allocation of employees to projects with clients.

All of the employers who were interviewed indicated that they would encourage employees to do some form of study both formal and informal post employment. CPD can be formal and informal, on-the-job experience, training courses and full accreditation and membership of professional bodies.

Chartered accreditation was indicated as very important by almost all employers interviewed as a means of measuring professional competence amongst peer groups and as a business imperative as an assessment criteria for pre qualification of work in the tender process in an increasingly competitive market. Employers indicated the value of short, modular courses for continuing professional development of employees and the development of employability, professional and soft skills were important for employees. With this in mind it is important that higher education continues a dialogue with industry to map the fit between the graduate labour market and employer/industry needs and future skills development of employees as highlighted in national and Welsh policy outlined above. It is important that there is an understanding of the need and motivation for training from employers through the development of short courses, and soft skills to delivery of compulsory components of CPD, so that Higher Education can develop this in a logical and coherent way.

Shortened degree courses

The University and College Union Briefing Paper (UCU 2010 p2) in response to the Government announcement to support an increase in the number of 'fast track', two-year degree programmes expressed concerns that *"fast track programmes will make it harder for students to combine study with periods of reflection, critical thinking and a 'deep approach' to learning"*. The final evaluation of the HEFCE funded Flexible Learning Pathfinder project reported the Pathfinders have had some success in introducing, sustaining and developing flexible provision, particularly accelerated degrees and work based learning with some potential, in the new fees and funding environment from 2012-13, for the expansion of flexible provision, although it notes the current high demand for traditional degrees. Detailed statistics on study outcomes and student employment destinations were not available at the time of the evaluation. However, there is some evidence in the HEFCE Pathfinder project that accelerated degree students' achievements are comparable t those of equivalent three year degree students.

This view appears to be reflected to some extent in the employer views captured in this study where 58% of employers said that they would value a shortened degree as they felt it would provide a more attractive option to mature/older learners, potentially lower student drop-out rates and offer a solution to allow people to enter the job market more quickly.

Employers who felt that a three year degree has merit and should be preserved within the modern education system welcomed the time afforded for introduction of concepts and for people to develop meaningful maturity of these concepts over a three year period in preparation for their future career in construction and for the opportunities it provides during holidays for valuable work experience. Also for the added value it provided to enable students (especially school leavers) to mature into world of employment. This

reflected the views expressed by the University and College Union (UCU 2010) that fast track programmes will make it harder for students to combine study with periods of reflection, critical thinking and a 'deep approach' to learning.

A general degree in construction

Employers were positive about the usefulness of developing a general degree in construction. However, the need for accreditation of employees i) to demonstrate professional competence and ii) to increase desirability to clients, in an ever competitive marketplace presents a paradox. For example, the requirement to achieve the RICS competencies is somewhat at odds with development of a general degree and places employer attitudes towards the development of course content somewhat at odds with the requirements of professional bodies, e.g., RICS. In support of this the (RICS 2011) highlighted the conflicting concerns that have long fuelled the "education versus training" debate and conflict between educators and employers through which RICS steers a sometimes difficult path.

Nevertheless the decision to specialise or pursue a more generic qualification has far reaching implications for employees in relation to employability post graduation. The sector is dominated by small to medium sized companies with a small number of employees. In such organisations the job prospects of a generalist are good however the job prospects of a specialist would be more favourable than those of a generalist in a large company with a large number of employees. Job placement as part of university courses tends to be with medium and large sized companies, this begs the questions: 'would students pursuing a general degree be disadvantaged?' and 'would there be a mismatch in qualification and employment placement requirements?'

CONCLUSIONS

Almost half of those interviewed specified the need for employees to have a relevant degree on entry into their chosen field of occupation. Employees were expected, and/ or encouraged to progress educationally after becoming employed. Almost all of the employers who were interviewed indicated the importance of chartered status for employees. Overall employers felt that skills training and experience were equally as important as professional and academic qualifications.

It was encouraging to discover that the three year traditional degree is still viewed as an important and relevant learning mechanism by employers in the construction industry. It will be interesting to discover the full impact of the findings of the HEFCE funded Flexible Learning Pathfinder projects, the economic climate, and new fee increases on student numbers, the degree and Higher Education.

Despite high levels of support from employers for the development of a general degree in construction (as a potential means for attracting new students post A level) problems with accreditation to professional bodies, e.g., RICS, due to the need for completion of Mandatory and Core competencies present barriers to flexible development of such courses in the near future.

STRATEGIES TO ADDRESS SKILLS SHORTAGES IN THE NIGERIAN HOUSE CONSTRUCTION SECTOR

Oluwole Joseph Oni[1] and Jacobus Jasper Van Wyk[2]

[1]*School of the Built Environment, Nelson Mandela Metropolitan University, South Africa*

[2]*School of the Built Environment, Nelson Mandela Metropolitan University, South Africa*

ABSTRACT

The current skills shortages in Nigerian House Construction Sector has constrained the productive capacity of the sector and aggravated the nation's housing problem. Past policies have largely failed to address the realities of the skills crisis occasioned by a weak and neglected apprenticeship and poorly developed vocational education and training systems. Insufficient research efforts directed towards skills concerns, non participation of employers in training, lack of recruitment strategies and a faulty and rigid National Qualification Framework are major factors negatively impacting the construction skills development. This paper reports a pilot study of a doctoral research work with a focus on technical colleges in charge of the formal training. Strategies for addressing the skills crisis are offered. These include education policy reforms to give priority to vocational education; adequate funding of the vocational education, a review of the National Qualification Framework to integrate the colleges with the university system; reforms of the policy framework establishing the regulatory mechanism; public reorientation on image of the artisans and provision of incentives schemes to attract potential artisans.

Keywords: construction, housing, skills shortages, strategies, training.

INTRODUCTION

Housing has been accepted as one of the three basic needs of mankind. It is most important for the physical survival, after the provision of food (Agbola and Olaoye 2008). Adequate housing contributes immensely to the physical and moral well being of a nation and advances social stability, work efficiency and the development of individuals. It is also one of the most suitable indicators of a person's standard of living and other standing in the society (Osowe, 2011). Housing problems remain a global phenomenon in the developed and developing nations of the world.

Nigeria has a population of over 140 million and an estimated growth rate of 3.2% (Nigerian National Population Census, 2006). Consequently, Nigeria has an enormous housing deficit, estimated at 12-14 million housing units (Akeju, 2007; Aikhorin,

[1] s211051039@live.nmmu.ac.za; browoleoni@gmail.com
[2] jj.vanwyk@nmmu.ac.za

2008). At an average cost of N2.5 million per housing unit, Nigeria would require N35 trillion (about USD24 billion) to fund a housing deficit of 14 million housing units.

Many factors are responsible for this acute housing problem the world over; these are entrenched in the components of the housing delivery system (Jinadu, 2004). They are Land, Finance, Human Resources, Building Materials, Government Policies, Construction Technology and Regulatory Mechanisms.

This study investigates the human resources aspect on the supply side of the problem, with specific focus on artisan skills development for housing delivery in Nigeria. This has been identified by several authors as a major challenge to adequate housing provision (Awe, Stephenson and Griffith, 2010; Adeloye, 2008; Akindoyemi, 2005; Agbola, 2005; Eneh, 2010; Olaoye, 2007; Fatimilehin, 2010; Jinadu,2004; Nworah, 2008 &UN-Habitat, 2008; Agbola and Olaoye, 2008). The following sections describe the problem, the context, the technical college system, the importance of artisan skills development, the methodology, findings and conclusions of the study.

THE PROBLEM STATEMENT

Sanni and Alabi (2008) observe that persistent neglect of the artisan training system by government has led to a drastic fall in enrolment of new intakes into building trades in the technical colleges in Nigeria. Consequently, it created a gap between demand and supply of artisans. This gap became wider with increased investment in shelter provision especially by individuals and families due to fast rising housing rents caused by pressure for accommodation especially in the urban centres (Agbola 2005). Dainty, Root and Ison (2004) contend that employers' indifference to investment in artisan training negatively impacts the supply of the required workforce for construction work. In Nigeria, employers' participation in artisan training is almost nonexistent, which further widens the gap between demand and supply of skilled artisans. The fallout of this is manifest in the difficulties faced by developers in sourcing suitably qualified and experienced artisans for house construction projects. Adeloye (2008) laments that

…."*yes there is lack of trained artisans in the country, and that only construction firms can sort it out, ...we have to sort out a unified building construction training scheme that trains our artisans and probably rewards those skills".*

Nworah (2008) reports that there is an upsurge of migrant artisans and craftsmen from neighbouring African nations like Togo, Benin Republic and Ghana in the recent time to Nigeria attracted by building contracting firms to fill the gap created by inadequate artisan supply locally. This is totally unacceptable in a country that has a high unemployment rate of 20% (NPC, 2006)

Given the exponential growth rate of Nigeria's population which was put at 3.2% by the Nigeria National Population Commission (NPC 2006); by this factor, new households are being formed pushing upward the demand for more housing units, hence the demand for more construction artisans such as masons and carpenters. Jinadu (2004) submits that the rise in disposable income since the return of democracy in 1999 has positively impacted on housing affordability of many public servants. The Federal Government of Nigeria (FGN) Vision 20:2020, a developmental plan to transform Nigeria to one of the top twenty economies of the world by the year 2020 is another point of concern that requires a large stock of artisans for its realisation. An estimated sum of one hundred and eighty billion Naira (USD1.2

billion) is to be spent on housing to construct 840,000 housing units. The study seeks to address the challenge of house construction artisan shortages with the view of developing appropriate strategies for an adequate supply of artisans.

SHORTAGE OF SKILLED ARTISANS FOR THE HOUSING DELIVERY PROCESS

There is an acute shortage of skilled artisans who are needed for the transformation of design to physical reality. Artisans such as masons and carpenters are in shortage both in quantity and quality (Agbola and Olaoye, 2008). A stakeholder in the industry remarked:

> '*……there is a great lack of skilled workers in the housing construction market; we need them in various shades…*' (Wharton, 2008).

The scarcity is not only in number but also in quality. The few available ones have very poorly developed skills which are usually evident in their poor workmanship, leading often to non-conforming work and reworks. The overall implications mean a cost and time overrun on contracts, increased maintenance costs and the reduced life of the building (Han, Lee, Fard and Pena-Mora, 2007). Nworah (2008) states that there is an upsurge of outsourcing of skilled artisans from neighbouring countries like Togo and Ghana to save time and cost. Nworah (2008) observes that this is a worrisome development and suggests that there is a need for government to re-focus on technical and vocational skills development to service the construction industry.

According to Fatimilehin (2010), artisans are vital to efficient housing delivery and the sector creates employment in most economies. However, in Nigeria, the persistent shortage of local skilled artisans has made developers and contractors resort to importing such skilled hands. Fatimilehin (2010) maintains that Nigeria loses a lot of money in capital flight to foreign skilled artisans and yet there is a serious unemployment crisis within the country.

THE NATURE OF ARTISAN TRAINING IN NIGERIA

There are two main systems of artisan training in Nigeria, namely the traditional apprenticeship system (informal training) and vocational technical college system (formal training). The focus of this paper is, however, on the latter system

TRADITIONAL APPRENTICESHIP SYSTEM

Traditional apprenticeship in Nigeria exists as a form of an agreement between a master-artisan and the apprentice. The apprentice is trained for a specified craft or trade through practical experience under the supervision of the master-artisan. It is a form of on-the-job training which allows the apprentice to learn by observation and practice (Iyamu and Uwameiye, 2002). This is a common method of training youths in trades and crafts to become empowered economically through jobs like carpentry, painting, bricklaying and decorating. The youth have developed apathy to skill acquisition as they prefer alternative approaches that will fetch quick money instead of learning a vocation (Eneh, 2010). The present stock of artisans is ageing and many of them do not have new apprentices to mentor and knowledge transfer is made difficult. This poses the great danger of extinction of the apprenticeship system (Eneh, 2010).

VOCATIONAL TECHNICAL TRAINING COLLEGES IN NIGERIA

Vocational Education is any form of education whose primary purpose is to prepare persons for employment in recognized occupations (Ajokorise, 2010). It has also been explained as the sum total of all educational experiences systematically organized and presented by an institution to enable the learner to acquire basic productive and practical skills (Oharisi, 2007).

Therefore, Vocational Education, also called *Career and Technical Education*, prepares students for jobs and careers that are based on mostly manual or practical activities. The term does not apply to the development of professions acquired via tertiary institutions. Vocational education is low on theoretical or academic activity and is generally related to learning a specific trade or occupation. It is sometimes referred to as *technical education,* as the learner directly develops skills in a particular trade that promotes considerable self-employment.

Vocational education teaches procedural knowledge for acquiring a skill or trade in contrast to general education that concentrates on theory, abstract knowledge and research. Vocational education provides instruction that is usually given to those who need employment in commerce and industry or in any type of enterprise that involves the use of tools and other machinery (Ajokporise, 2010).

PROBLEM WITH TECHNICAL AND VOCATIONAL EDUCATION IN NIGERIA

Vocational education and training offers the best opportunity to produce an employable work force in any country. Oni (2006) argues that in the distressed economies of the third world, there are no clear and workable policies in place for vocational education and technical training. Educational policy implementation in Nigeria, for example, is haphazard. The 6-3-3-4 education policy, (which means 6 years in the primary, 3 years in junior secondary, 3 years in senior secondary and 4 years for tertiary education), that was designed to develop middle cadre technicians has collapsed. Oni (2006) opines that every developing nation needs the efficient service of technicians, engineers and technologists who have received formal training from vocational-technical institutions.

The vocational technical colleges have been generally ineffective and largely neglected by government (Aturu 2011). Education policies are unfavourable to the vocational segment making no proper provision for its integration into the National Qualification Framework (NQF) and as a result, career progression is difficult for vocational graduates (Aturu 2011). African Union (AU) (2007) asserts that in many African nations the quality of Technical and Vocational Education and Training (TVET) institutions is low, instructors' trainings are inadequate and training equipment are outdated. This unfavourable learning environment negatively impacts the quality of the products who are the artisans. Aturu, (2011) submits that there is a poor public perception of technical and vocational education and training; it has been considered as a career path for less academically endowed. African Union (2007) argues that TVET is left for the rural poor and the economically disadvantaged to learn a trade. This perception has been fuelled by the academic requirement for admission and limited prospects for further education and career development. AU (2007) further states that the worst impression is sometimes created by government

that the primary objective of vocational education is to keep the dropouts off the streets rather than project this type of training as an effective strategy to train skilled workers for employment and for sustainable livelihoods. Aturu (2011) contends that while the United Nations Education Scientific and Cultural Organisation (UNESCO) recommends that at least twenty six percent (26%) of the national budget should be allocated to education, in Nigeria, it has always been less than ten percent (10%). For instance in the 2010 budget, N249.08 billion was allocated to education out of a budget of N4.07 trillion which translate to six percent (6%) of the total budget (National Budget Office 2011). Vocational education is worst hit by the inadequacy as it is maginalised in the sharing of education allocation from the national budget. For instance, available data indicate that out of the allocation for education in 2003, 2004 and 2005, vocational education only got 20.9 percent, 7.1 percent and 13 percent respectively (NBTE 2008). Vocational training in Nigeria is largely uncoordinated and lacks proper government regulation and intervention.

METHODOLOGY

A quantitative research survey was conducted with a focus on the technical colleges which engage in formal training of the house construction artisans using a structured questionnaire and physical survey/observation. This was coupled with an extensive review of literature. Fourty eight (48) questionnaires were administered on the management and other staff members of twelve vocational technical colleges to elicit information on issues relating to training such as teaching and learning strategy; staffing; physical infrastructures; training facilities and library resources; regulatory mechanisms; Government policies and level of funding. Fourty two (42) were returned and analysed representing 87.5% return rate. Additionally, physical survey/observation was carried out in the colleges to get an insight into physical infrastructures and training facilities available for training and how artisan training takes place in practice.

FINDINGS AND DISCUSSION

The study exposes major concerns among the stakeholders of the formal training system of house building artisans. The respondents were quite aware of the situations facing the training system and the impact of the skills shortages on the House Construction Sector. It was found that the regulatory mechanism for the technical training colleges, the National Board for Technical Education (NBTE) is weak and ineffective; giving inadequate attention to quality and standard regulations. The (NBTE) has almost neglected the technical training colleges to run on their own, this is partly due to too large scope of operation to cope with as the same NBTE is responsible for 57 polytechnics, 43 monotechnics apart from the technical colleges. Its emphasis seems to be on the polytechnics at the expense of the technical colleges, thus leading almost to a state of system collapse of the technical colleges. The stakeholders within the Polytechnics system have always requested for a separate regulatory body, the National Polytechnic Commission, (NPC), so that NBTE will be able to give dedicated attention for technical colleges while the NPC takes care of the polytechnics. However, till date this is still being resisted by those opposed to vocational education among the policy makers.

The available physical infrastructures such as offices, workshops, classes and hostels are grossly inadequate, 40 respondents representing 95% indicated that the conditions of the buildings in the colleges are lacking adequate maintenance. 32 respondents representing 76% agreed that the colleges surveyed do not have appropriate buildings for the library while 34 respondents representing 81% opined that relevant textbooks, IT infrastructure and other resources required for proper training were lacking in the colleges. Workshop equipment for practicals were found obsolete by the researcher and 29 respondents representing 69% agree that the training equipment were outdated. While the level of practicals conducted for trainees are grossly low, the training contents are more of theoretical instructions; 30 representing 71% of the respondents said the review and update of teaching methods are not regularly carried out as expected. 38 representing 90% of the respondents indicated that the available teachers are grossly inadequate due to government reluctance to employ more staff, coupled with poor remunerations and other conditions of services. 61% of the respondents believed the qualifications of the teaching staff members were inadequate, many having the minimum teaching qualification requirements, the National Certificate of Education -technical (NCE). This is not unconnected with a general absence of staff development policy in place in the college system. All the respondents agree that the level of funding received from the government for running the colleges is grossly inadequate.

Government policy on technical and vocational education as compared with general education is imbalance; most respondents (95%) indicated that the Government policy framework on the rating of technical college certificates is poor; the policy on career progression with technical certificates is harsh, making no provision for integration with the university, thus making vocational education system a dead end. This has negatively impacted the societal image of construction workers and other vocational graduates. The operation of a rigid National Qualification Framework (NQF) is a potential factor that is responsible the poor patronage of the technical colleges. Policy makers, most of whom are drawn from the university system are biased against vocational technical education, holding the belief that vocational education is inferior and meant for the educationally disadvantaged fellows or dropouts in the society. Therefore, in their policy making process, they deliberately oppose attempts to make provisions for career progression for vocational graduates through creation of proper integration path with the university system.

STRATEGIES

Efforts to create a sustainable future supply of construction skills for the House Building Sector must begin with a genuine and unbiased policy reforms in the education sector. Authorities should give appropriate recognition to vocational education backed with a robust media campaign to promote its careers. This must be followed up with a strong political will to implement the reforms; as unimplemented policy is as bad as poor policy provisions. A flexible NQF is required where vocational qualifications are integrated with the University to ease the career progression of its aspiring graduates. A solution to the challenge of standard and regulation would require a dedicated regulatory mechanism for the technical colleges to monitor and maintain a high quality standard in the training of artisans for the Construction industry. This will require regular visits for programme accreditation and institutional auditing of the colleges. An entirely new regime of funding is needed to make available adequate physical infrastructures, appropriate training facilities,

library resources, IT infrastructures and training incentives or scholarships to attract new entrants to the colleges. Provisions for staff development policy are necessary for training and retraining of technical college teachers; Improved salaries and robust welfare packages for teachers are imperatives to attract talented human resources to the system. Encouraging employers to invest in training will boost the productive capacity of the colleges and in turns reduce the skills shortages.

CONCLUSIONS

This study is set out to collate and synthesise the most appropriate ways to tackle the skills shortfalls currently affecting the house construction sector with a focus on the technical colleges saddled with the responsibility of formal training of artisans. The research has revealed the need for a strategic skills policies formulation and a combined approach for skills planning in order to mitigate skills shortages and provide for sustainable future skills supply.

ABSTRACT

This study was seeking to showcase the construction industrial requirements of the construction graduates, employability levels and their contribution to the industry. Graduates from two universities (Witwatersrand and Pretoria were chosen, in the period 2007 to 2010, were contacted through emails and telephone. The graduates in all cases felt they lacked confidence in their ability to perform effectively without supervision. There was discrimination between the graduates from both universities as the managers were biased towards their alumni. The site managers because of the nature of the construction industry could not entirely trust the graduates to run a site until experienced. However the industrial leadership was satisfied with the qualifications of the graduate's as they have been involved in the design and lecturing of these courses as some of them are external examiners. Some of the graduates within this province are no longer linked to these universities at all. Some of the graduates have changed professions into other fields or left the country. It is important that students before graduation should fully understood the nature of the construction industry by periodically visiting construction sites, and carryout some problem solving researches.

Keywords: employability, industrial expectations practical skills, skills mismatch and sustenance.

INTRODUCTION

A student who has graduated is expected to be ready for the workplace; to have the skills and ability to apply knowledge effectively using a minimum outlay of time, cost, and energy. However, according to Pauw, Oosthuizen & Westthuizen (2007) graduates making the transition from university to the workplace lack the practical skills required in the construction industry, and there is a mismatch between the skills provided by graduates and those required by the industry as "priority skills", specifically, practical skills.

Background

The government has been promoting skills development in South Africa for many years through bursaries, youth programs, scholarships and awareness. One area that has not been properly addressed is the development of practical skills to a level of sustaining the construction industry. In this study it was found that there were three possible reasons for skills shortage in South Africa. The first is the legacy of apartheid on the educational system, the second is the impact of post-apartheid emigration in the construction industry and the third is the mismatch between the skill requirements of employers and the skill output of the universities. According to the National Planning Commission of South Africa (2011), there was a significant increase in student enrolments in the period 2001–2010 and student enrolment has been increasing by an average of 4.6 present per year, but under-preparedness of many learners entering tertiary institutes demand for support programmes that many tertiary institutions find increasingly difficult to meet. According to Bailey (2003) since 1994, there has been an increasing net loss of skills from South Africa. It was estimated that 2 891 professionals in the built environment and engineering field left the country in comparison to the 1 063 that were immigrating to South Africa between the period of 1994 and 2000.This has prompted an increase of professionals emigrating to 6.2% each year since then. The main factors prompting emigration for young professionals are the opportunity to gain international work experience and the cost of living in South Africa.

History of education in South Africa

Education is the key process that is used to link the individuals, cultures and the economy in order for the environment to run smooth and effectively. Society is constantly changing and for the individual to survive, education is needed (McKerron, 1934) When the Dutch settled in South Africa in 1652 they never had colonization as their main aim, it was the Dutch East India trade, but in Holland the government funded education and the Reformed Church ensured that sound religious teachings where put in schools. The Cape settlers were so proud of their mother countries teachings that they tried to carry on those principles in South Africa. According to McKerron (1934) in the beginning of the nineteenth century, a desire of higher education started to be noticeable because the number of posts in different fields such as construction and there was now a need for professional men. He summarised the development of higher education as follows;

		Year
South African College (Cape Town)	115 students	1829
Financial problems reduced to	20 students	1843
Annual grants by Government made available. pounds/student	200	1843
Finance from shareholders also came in		1878
University of Good Hope established similar to the University of London (1828)		1873
University act 1916 established 3 Universities a) University of Cape Town b) University of Stellenbosch c) university of South Africa (UNISA)		1918
TECHNICAL COURSES offered by South African School of Mines (Kimberly to Johannesburg later)		1996
Transvaal Technical Institute (Johannesburg)		1904

Changed to Transvaal University College	1908
Two Campuses Pretoria and Johannesburg	1910
University of Witwatersrand	1921
University of Pretoria	1930

South African labour market

The Employment equity act was introduced in 1998 to empower affirmative action in South Africa. This act was designed to restructure the economy and create fair, equal and non-discriminatory opportunities for all. The department of labour has a right to send out inspectors to investigate if employees are complying with this act. (Burger and Jafta, 2010). However the main criticism of the Employment Equity ac t is that the government does not have enough qualified inspectors to ensure accurate data is recorded. Without proper inspections companies can ignore this act. (Bezuidenhoud et al, 2008).

Women in construction

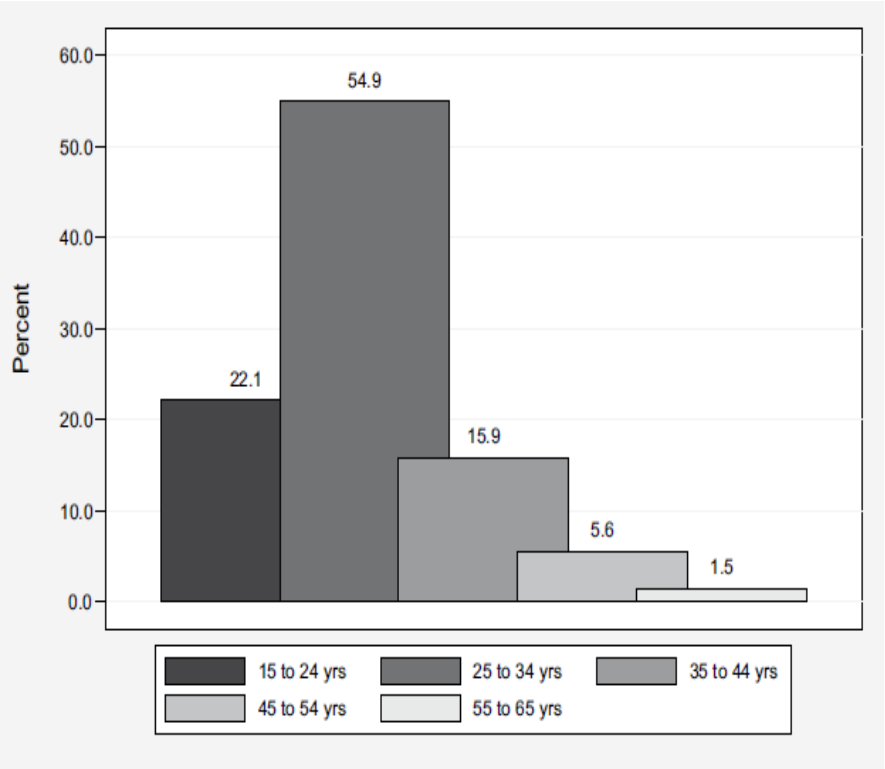
In a research conducted by Lin (2000) it was found that women make 50% of the population in South Africa and more than half of the women do not finish high school to get a Matric qualification which means these women do not have degree qualifications to be properly skilled to achieve top management, but however there are 5% of women who finish high school and acquire further education. Construction courses offered by universities are designed for both males and females and the workload is manageable by both male and female students .According to Lin (2000) for an individual to achieve a managerial position, a university degree is not the only requirement but still need good site experience that will enable the individual to understand the practical part of the industry rather than having a theoretical background. To get practical training and knowledge required from site is a challenge for a female graduate because construction is seen as a male industry and members of the construction industry prefer not to have women on site. Women are excluded from formal and informal training. Lin (2000).Further research by (Eksteen & Oosthuizen, 1996) found that there are 0.5% to 1% of female construction management graduates every year but the number of women entering the industry remains low because even though the individual has a degree, they do not get the practical experience required.

Skills shortage and unemployment

The construction industry forms an important part of the South African economy. It has undergone important changes and has been faced with new challenges in growth which can be largely attributed to changes in the country's political state of affairs. South Africa's economy has experienced an increase in productivity since its exposure as a democracy, leading to increase in pressure to compete in the world market. Resultant or, ripple effects were that industries had to be adjusted and upgraded to levels capable of achieving the desired production outputs, the large workforce required to produce at higher output rates had grown to include previously disadvantaged groups (though at first the change was concentrated in the semi to non-skilled work, in time it grew to include skilled / educated persons who now had opportunities to access fields in higher education), and an increase in the demand for skilled labour (I.e. specialised skills), to name a few. (Pauw, Oosthuizen, Westhuizen, 2006). All these effects have contributed to the economy developing a skills-biased labour market demand.

Graduate unemployment

In 2005, Statistics South Africa estimated that a total of 77 per cent of unemployed graduates were in fact youth, defined as individuals who fell within the age bracket 15 to 34. This suggests that majority of unemployed graduates are recent graduates (Kalie Pauw, Morne Oosthuizen, Carlene Westhuizen, 2006). The age composition of unemployed graduates is illustrated by the graph below:



(Statistics South Africa, 2005)

GRAPH 2.7.1.1: AGE COMPOSITION OF UNEMPLOYED GRADUATES, 2005

"The phenomenon of unemployed graduates, who are without abilities to self-employ and self-determine, after spending three to four years of post-secondary education is an indication to all of us of the challenge in our education at a tertiary level…the curriculum developers are not paying enough attention to issues of relevance and ensuring that we all pay attention to the skills and competencies learners require when they come out of higher education… we need a skills revolution in the curriculum of tertiary education."- (Mlambo-Ngcuka, 2006)

In 2005, Kraak suggested that poor throughput statistics at universities and technikons in South Africa "are yet another indication of the weaknesses of school education which should provide a more adequate preparation of entry and success in further higher learning", while, "the perceived poor quality of South African schooling (particularly in the former Bantu-education school system) serves as a major disincentive on the demand-side for employing first time entrants to the labour market.

Organisations in the South African Construction Industry

A List of some of the known organisations studied in this research.

- Construction Education and Training (CETA) after the Skills Development Act, no 97 of 1998
- Education and Training Quality Assurance (ETQA) by the South African Qualifications Authority (SAQA)
- Master Builders South Africa (MBSA)
- Master Builders and Allied Trades' Association. (the MBA)
- Association of Quantity Surveyors (ASAQS)
- Construction Industry Development Board (cidb)
- South African Council of Quantity Surveying Professions (SACQSP)
- Council for the Project and Construction Management Professions (SACPCMP)
- National Contractor Development Programme (NCDP)
- Chartered Institute of Building (CIOB)

POSSIBLE REASONS FOR PEOPLE LEAVING THE CONSTRUCTION INDUSTRY

The industry

The construction industry is one of the biggest industries mainly because the construction industry is not just a single industry, but it comprises of many sub-industries (Ive&Gruneberg, 2000).

Different groups

The construction industry is one of the most criticised industries in terms of its employment practices. The construction industry relies heavily on informal employment. Construction projects are done by a combination of firms and individuals that most likely have never worked together before or possible will never work together with again. Different groups of people are bought together and are expected to form a working relationship quickly and deliver successful projects. This creates tension among employees and tension arises from time and cost constraints (Dainty, Green, Bagilhoe, 2007). Research done by Haupt (2008) found that the facilities on sites need improvement and that the overall mind set of consultants need to improve. The construction industries health and welfare policies on site are not the same as the ones in the manufacturing industry. Workers in the manufacturing have better working conditions than construction employees. The research also found that the overall image of the construction industry was negative. These factors stated can demoralise construction employees. Haupt (2008)

Health HIV/Aids

HIV/Aids are a major contributor for workers leaving the construction industry. South Africa has one of the highest aids rates in the world and the construction industry is also affected. The elder construction artisans are the ones who are mostly affected and a possible reason for this is awareness. Some employees do not realise that they have the virus and hence do not get the treatment needed. (Haupt, Smallwood, 2003).

Other opportunities

Students who studied B.Sc. Construction management, B.Sc. Quantity surveying and B.Sc. Property studies can branch off into different careers paths such as project management, consultation, Human resources, lecturing, and property development. (Witwatersrand, 2011).

 ISBN: 978-1-84219-840-7 .

CAREER PATHS

Quantity surveyor

According to The South African Council for the Quantity Surveying Profession (SACQSP, 2011) after obtaining a Quantity Surveying degree or other relevant qualification candidate quantity surveyors are required to do at least 33 months of in service training work under the supervision of a qualified quantity surveyor as the qualified quantity surveyor plays a crucial role in the training process and depending on their qualification, pass the council exams in order to prove their professional competence before they are allowed to register with The South African Council for the Quantity Surveying Profession. Qualification requirements (Quantity surveyor and Construction manager)

Construction Managers

According to The South African Council for the Project and Construction Management professions (SACPCM,2011) states that a minimum requirement to be registered as a professional construction manager is an accredited honours degree in the built environment field of study with a minimum of four (4) years' relevant post-graduation practical experience. According to (careerjet, 2011) the general requirement for posts in construction management is 7- 10 years' experience in the construction industry, this rules out the chances of graduates landing positions because they compete with experienced professionals.

RESEARCH METHODOLOGY

Qualitative research is any kind of research that produces findings not arrived at by means of statistical procedures or other means of quantification. Strauss and Corbin, (1990, 17) In simple terms qualitative research is data collection from observations, in depth interviews and questionnaires. Observational techniques are methods by which a researcher gathers first-hand data from programs, processes or behaviours being studied. Interviews involve direct interaction between the researcher and a respondent or group.

Population group

The population was limited to graduates entering the construction industry only and those who are job hunting or already working in the Gauteng province from the period 2008 to 2010. The issues that affected the selection of the population group are; experience in the construction workplace, abilities (looking at those possessed by graduates and those expected by employers in the construction industry) when making the transition into the workplace, as well as workplace performance. The groups of students and employers interviewed were diverse in order to represent the population make-up of the country itself. The questionnaires were not biased on culture, religion, or gender association. After randomly contacting (25 graduates responded) from the University of Witwatersrand and the others from University of Pretoria and issued questionnaires to the select group of graduates to see which graduates settled better in the construction industry. This in turn highlighted which curriculum is better suited to meet requirements of the industry. The study also identified eight construction companies (three large prominent companies, and three medium to small sized companies) to find out what they also expect from graduates by issuing questionnaires and conducting interviews.

A random selection technique was selected to choose eight construction companies in Gauteng. Three large prominent companies (can handle projects greater than R50 million); three medium companies carrying (can handle projects greater than R10million but less than R50 million) and two small companies (can handle projects less than R10 million). Questionnaires were issued to the managers of the various construction companies. A random selection technique was also used to choose the sixteen students, from the University of Witwatersrand and University of Pretoria which questionnaires were issued. This was done by telephone, mail and personal interviews.

Data Analysis

Results from interviews and questionnaires with, graduates and employers, were captured and used as research data for analysis. Data was acquired though face to face interviews and administration of questionnaires, phone interviews, and emailing questionnaires to respondents. All graduate respondents were qualified graduates within the construction industry (who were practicing in the industry). Pie charts were used to present the outcomes as they best illustrate percentages of a whole (best for respondent questionnaires). Bar charts were used where also used as a tallying of results was required, where a pie chart would not be suitable.

CONCLUSIONS

The findings showed that graduates generally felt that they were not exposed enough to information about their profession during their studies. Graduate respondents felt that they were not prepared for the industry; graduates felt that they had been less exposed to the industry's practical activities than they should have been, citing that, although they'd done the work in theory, the real life experience of the work was very different. This in turn had a negative influence on their confidence and progress in settling in on site. The results indicated that a great majority of the employers agreed that graduates have enough skills for the workplace except that they feel they may require more practical experience to better familiarize the student with the construction industry's work environment, which is heavily reliant on practical application and experience. This ability to apply skills can be achieved through tertiary institutes requiring a certain amount of time working in the field (vacation work), from all graduates in the construction industry, as due performance. This could also be achieved through construction industry organisations and associations investing in their newly qualified professionals by setting up learnership and apprentice programs. We can therefore conclude that although most employers are satisfied with graduates' overall performance, they highly value practical experience or prior exposure to the workplace and that the presence of practical experience in the graduates past can impact the graduates' ability to make their transition from their respective tertiary institutions to the construction industry.

RECOMMENDATIONS

Employers felt that the graduates had enough skills for the workplace and hence the problem lies with the graduates having confidence in their ability and being able to apply what they learnt. In order to instil confidence in the graduates universities must expose students to site conditions to familiarize them with their later working environment by requiring all construction graduates to achieve due performance as a necessity before they are deemed qualified. Graduates could also be put through training and internship programs by either the organizations within the construction

industry or by companies looking to employ the graduates before they start working. Construction organizations must be more involved than just giving memberships to the student. If they do not already, then they should consider providing mentorship programmes to their members. They could also sponsor some research in common problems that are encountered on construction sites as research topic or areas by final year students.

AN ASSESSMENT OF THE LAGGED EFFECT OF INFLATION ON BUILDING MATERIAL PRICES: THE CASE OF NIGERIA

Saka Najimu[1] and Lowe John[2]

[1&2]*School of Engineering and Built Environment, Glasgow Caledonian University, Glasgow, Scotland, United kingdom G4 0BA,*

ABSTRACT

The construction industry as one of the single largest industries in Nigeria makes significant contribution to employment, capital formation and Gross Domestic Product etc. However, the optimal performance of the sector is hampered by the volatility of building material prices. The study investigated the lagged effect of inflation on building material prices. Data were extracted from Central Bank of Nigeria (CBN) statistical bulletin and Guardian newspaper monthly publication of building material prices. The Distributed Lags Model (DLM) was used to analyse the effect of inflation on building material prices. The result shows that inflation or price level movement has a significant impact on building material prices between three to six months after their occurrence. The paper recommends that effort should be made by government to stem the tide of inflation through improve agricultural production, mining and local production of building material.

Keywords: Building Material Prices, Distributed Lag Model, Inflation, Lagged Effect, Nigeria.

INTRODUCTION

Inflation is born out of lack of effective monetary control. The high rate inflation in the Nigerian economy is a result of the creation of money by government that has no regard for the absorption capacity of the economy (Olashore, 1991). The phenomenal increases in the price of petroleum products in the mid-1970s and the foreign exchange crisis in 1980s further steams up the price rise (Uwah, 1995). Inflation undermines the rules of business, creates havoc and financial ruin of even the prudent. Inflation discourages savings, investment and productive activities given that the future value of money is not certain. The Uncertainty about future price levels could force investors to delay investment decisions, since investment is a sunk cost and largely irreversible. Without

[1] saka.najimu@gcu.ac.uk
[2] j.lowe@gcu.ac.uk

 ISBN: 978-1-84219-840-7 .

this uncertainty, consumers and producers could better plan for the future (Pindyck, 1991). No doubt one of the greatest problems facing Nigerian construction economy is persistently complex inflation (Fakiyesi, 1996). Inflation may have negative effect on project cost and time performance and may result in dispute and even outright project abandonment (Jagboro & Owoeye, 2004). Indeed inflation has had a crippling effect on the Nigerian Construction Industry (NCI) with a significant reduction in construction facility investment (Anunobi, 1997, Fawehinmi, 1998).

BUILDING MATERIAL PRICES

Building material alone constitutes about 60 percent of the total cost of building construction (Olubodun, 1986). The rise in the demand for building materials began at the end of the Nigerian civil war (1967-70) when Nigeria embarked on a massive rehabilitation of its infrastructure (Wahab, 1985). High demand, inflation and the downward trend in the value of the naira have led to the rising cost of building materials at a far higher rate than the modest increases in other inputs (Ojimelekwe, 1999). The difficulties in maintenance, high foreign components as well as high installation and running costs, frustrate production and hike in prices of building materials (Ofoegbu, 1998). The inadequate local supply and the restriction placed on the importation of building materials to meet local demand have created a persistent rise in building material (Jagboro & Atigogo, 2000). The unfortunate trend in the building material supply situation is that demand has increased over the years while local production has stagnated or declined (Jinadu, 2004). Additionally the unwholesome activities of middle men who engage in hoarding and black market sale of building material exacerbates scarcity and reinforce the inflationary pressure (Jagboro & Owoeye, 2004). Building material prices have increased by more than twice the Nigerian consumer price index in the two decades (UNCHS, 1996). The availability, adequacy and prices of building materials form a crucial constraint to housing development programmes in developing economies (UNCHS, 1987 and Jinadu, 2004).

METHODOLOGY

The study adopted a time series econometric methodology to make a valid assessment of cause and effect relationship. Several sequential econometric procedures including test for unit root, cointegration and distributed lag model were used to determine the causal relationships between the variables. The data for this study were based on quarterly time series data on inflation and building material prices. Data on inflation which is measured by the Consumer Price Index (CPI) were sourced from Central Bank of Nigeria (CBN) statistical bulletin. Twenty (20) building materials including cement block, and aggregates were selected for the study. Quarterly data on these materials were sourced from guardian newspaper and journal of the Nigerian Institute of Quantity Surveyors (NIQS) for 28 quarters from 1999 Q1 through 2005Q4. The prices of these materials for each quarter were simply summed up to form a single index number or Aggregate Building Material Price Index (ABMPI). The common base quarter for the CPI and ABMPI is set at 1999/1. The Data used for the study covers a forty three (28) quarter period i.e. from 1999/1 through 2005/4.

Operational Definition of Variables

The Consumer Price Index (CPI): This is a measure of the average change over time in the prices paid by urban consumers for a market basket of consumer goods and services. The market basket includes the price of food, clothing, shelter, fuel, transportation and medical care etc. The CPI is constructed by weighting each commodity price according to the economic importance of the commodity of interest (Samuelson & Nordhaus, 2005). The CPI is used here to represent the general level of prices or inflation.

Aggregate Building Material Prices Index (ABMPI): this is an index of the prices of building material purchased by a typical house builder. It includes major material from agriculture (wood) to extractive/manufacture (sand, aggregates cement & paint etc) and imports (electrical fixtures) used as materials for building construction. The Prices of twenty (20) building materials were used to construct the ABMPI by simply summing up their prices in each quarter. The ABMPI is used here to represent building materials price/cost index. The ABMPI is computed as follows

$$\frac{\Sigma p_t}{\Sigma p_0} x100 \qquad \text{…(1)}$$

where Σp_t is the sum of all prices of the selected building material for the study in the current quarter t and Σp_0 is the sum of the prices in the base quarter p_0. The resulting time series generated are then converted into an index number of price movement of all the selected building material by dividing with the base quarter.

Analytical Techniques and Strategy

The study adopted standard econometric procedure including unit root test, cointegration and distributed lag model to investigate the effect of price level shocks on prices of building material.

Unit Root Analysis; If the underlying stochastic process that generated a series can be assumed to be invariant with respect to time, the process or series is non-stationary. If the stochastic process is fixed in time, the process or series is stationary. Stationary series can be modeled via an equation with fixed coefficients that can be estimated from past data. Many of the time series encountered in business and economics are not generated by stationary processes. Many of the non-stationary time series could become stationary after differenced one or more times (Nelson and Plosser, 1982; Pindyck and Rubinfeld, 1991). The study applied three widely used unit root tests including; the Dickey Fuller (DF) test, the augmented Dickey-Fuller (ADF) test (Dickey and Fuller, 1979) and the Phillips-Perron (PP) test (Phillips and Perron, 1988).

Cointegration Analysis; Regression analysis based on trending time series data can be spurious (Leitner, & Fischer, 2000, Gujarati, 2003). This problem of spurious regression led to the concept of cointegration (Granger and Newbold 1974 and Granger, 1981). Two time series are said to be co-integrated, when both are non-stationary, but a linear combination of those time series will be stationary (Engle and Granger, 1987). The stationary linear combination is called the co-integrating equation and may be interpreted as a long-run equilibrium relationship between the series (Leitner, & Fischer, 2000). Testing for cointegration is a way of testing the long term relatedness between time series data. If cointegration exists between the two variables, causality must exist in at least one

direction (Granger & Newbold, 1986; Granger 1988). The Johansen cointegration test (Johansen, 1988 and 1991) is used to test for the significance of cointegration between CPI and ABMPI. The two statistics that may be used to test for the presence of cointegrating vectors are the λ_{max} and the λ_{trace} statistics. The former is for testing the null hypothesis that the number of cointegrating vectors is r against the alternative of (r+ 1), while the latter for testing the null hypothesis that the number of distinct characteristic roots is less than or equal to r against a general alternative(Tan, 2000).

The Distributed Lags Model (DLM); in time series econometric the dependence of a variable Y on another variable(s) X is rarely instantaneous. Very often, Y responds to X with a lapse of time. A regression model involving time series data that include not only the current but also the lagged (past) values of the explanatory variables (the X's) it is called a Distributed Lag Model (Gujarati, 2003). Distributed lags analysis have been used extensively in economics since their popularization by Almon (1965) and have more been employed in virtually every sphere of quantitative analysis. Thus

$$Y_t = \alpha + \beta_0 X_t + \beta_1 X_{t-1} + \beta_2 X_{t-2} + \cdots + \beta_{t-k} + u_t$$
……………………………………………….(2)

is a distributed lag model. The coefficient B_0 is known as the short run, or impact, multiplier because it gives the change in the mean value of Y following a unit change in X in the same time period. If the change in X is maintained at the same level thereafter, then (B_0 + B_1) gives the change in (the mean value of) Y in the next period, (B_0 +B_1+B_2) in the following period and so on. These partial sums are called, interim, or intermediate, multipliers.

RESULT

Unit Root Test; The null hypothesis of unit root for the series in level form with and without time trend are rejected at all conventional levels of significance. The series were then transformed into their natural logarithm and first differenced and the unit root test rerun, the DF, ADF and PP tests statistics then reject the hypothesis of a unit root at all conventional levels of significance. The LCPI was stationary without differencing i.e. 1(0) while the LABMPI became stationarity after first differencing (i.e. I (1)). Table 1, shows the DF ADF and PP test statistics on the natural logarithm of CPI and ABMPI both in level and in the first differenced forms.

Table 1 Unit Root Test

Series	Dickey Fuller (DF) level		Augmented Dickey Fuller (ADF) at 1st diff		Phillips-Perron (PP) at 1st diff		Conclusion
	Constant, no trend	Constant, trend	Constant, no trend	Constant, trend	Constant, no trend	Constant, trend	
LABMPI	-0.404139	-4.998952	-5.949550	-5.814306	-21.63541	-20.98838	I(0)
LCPI	0.069950	-2.882286	-5.246785	-5.388416	-5.246785	-5.388446	I(1)

Cointegration test; Table 2 reports the results for the Cointegration tests , the result shows that the likelihood ratio (trace statistics) rejects the null hypothesis of no significant cointegration between LCPI and ABMPI since the likelihood ratios are greater

than the associate critical values at 5%. It could be inferred that there is a long –term equilibrium contemporaneous relationship between the variables and they have a common trend. The establishment of cointegration rules out the possibility of a spurious relationship between the variables, and suggests that a causal relationship must exist in at least one direction.

Table 2 result of Cointegration test

Series	Hypothesized No. of CE(s)	Eigen value	Trace Statistic	0.05 Critical Value	Prob.**
LCPI & LABMPI	None *	0.547304	31.77948	25.87211	0.0082
	At most 1	0.349331	11.17359	12.51798	0.0830

Trace test indicates 1 cointegrating eqn at the 0.05 level

In testing the lagged model for the relationship between LABMPI and LCPI, two simple models i.e. model (1) without lagged and model (2) with lagged values were estimated. The resulting equation of model without lag is presented in table 3

Table 3 model 1

Dependent Variable: ABMPI				
Variable	Coefficient	Std. Error	t-Statistic	Prob.
C	-479.1730	54.07225	-8.861718	0.0000
LCPI	126.1515	10.86865	11.60692	0.0000
R-squared	0.838228	F-statistic		134.7205
Adjusted R-squared	0.832007	Prob (F-statistic)		0.000000
Durbin-Watson stat	1.865110			

Table 4 model 1 diagnostic tests[3]

DIAGNOSTIC TEST	p VALUE
ARCH	0.591630
BG Serial Correlation LM	0.696746
Normality	0.000045
White Heteroskedasticity	0.696746

The sign of LCPI is positive, a priori. The DW statistic indicates no significant autocorrelation, supported by the p-value for the LM test for serial correlation statistic. The diagnostic test results each indicate accepting the null hypotheses,[3] with the exception of the ARCH test, which indicates heteroscedasticity in the model.

Table 5 model 2

[3] Diagnostic Test Hypotheses:
Serial correlation (Lagrange Multiplier test) H_0: No serial correlation. H_A: Serial correlation is present.
Functional form (RESET test) H_0: Well-specified model. H_A: Model mis-specified.
Normality test (Jarque Bera test) H_0: Residuals normally distributed. H_A: Resid. Not normally distrib.
Heteroscedasticity test (ARCH test) H_0: No heteroscedasticity. H_A: Heteroscedasticity is present.

Dependent Variable: LABMPI				
Variable	Coefficient	Std. Error	t-Statistic	Prob.
C	0.637085	0.334549	1.904309	0.0684
LCPI(-1)	0.876365	0.067494	12.98433	0.0000
R-squared	0.870863	F-statistic		168.5928
Adjusted R-squared	0.865697	Prob(F-statistic)		0.000000
Durbin-Watson stat	1.883600			

Table 6 model 2, diagnostic test

DIAGNOSTIC TEST	p VALUE
ARCH	0.790952
BG Serial Correlation LM	0.544473
Normality	0.109346
White Heteroskedasticity	0.371483

The resulting equation of model with lagged values is presented in table 5. The model fit is good adj. R^2 =87.08%. The sign of LCPI is positive a priori. Durbin Watson test indicates no significant serial correlation which agrees with the LM serial correlation test statistics. All other diagnostic tests suggest accepting the null hypotheses.
Experimentation with the addition of more lags of the independent variables i.e. LCPI was carried out and the adjusted R^2, AIC and SIC were used to determine the optimum lag model. The following final model presented in table 7 was estimated. Any further addition of the lags of the independence variables beyond two quarter lags resulted in wrong signage (negative sign of LCPI) of the independence variable which is not reasonable.

Table 7 model 3

Dependent Variable: LABMPI				
Variable	Coefficient	Std. Error	t-Statistic	Prob.
C	0.598516	0.376264	1.590681	0.1253
LCPI(-1)	0.492174	0.509199	0.966564	0.3438
LCPI(-2)	0.394793	0.532886	0.740858	0.4663
R-squared	0.865142	F-statistic		73.77459
Adjusted R-squared	0.853415	Prob(F-statistic)		0.000000
Durbin-Watson stat	1.980181			

Table 8 model 3, diagnostic test

DIAGNOSTIC TEST	p VALUE
ARCH	0.826736
BG Serial Correlation LM	0.414942
RESET TEST	0.520032
Normality	0.094307
White Heteroskedasticity	0.824893

Model 3, a distributed lag model is a model with two lags of LCPI (i.e. -1 and -2). The model fit is high with adj. R^2 =85.34%. The sign of LCPI is positive a priori. Durbin Watson test indicates no significant serial correlation which agrees with the LM serial correlation test statistics. All other diagnostic tests suggest accepting the null hypotheses at 0.05.

DISCUSSION

The distributed lag model clearly establishes that inflation impact on prices of building materials. As a matter of fact CPI or the price level affect building material prices significantly up to two quarters (six months) after their occurrence. Evidence from the model suggest that the coefficient statistics are insignificant even when the model R^2 and adjusted R^2 indicate a good model fit. This contradictory result of insignificant coefficient and significant R^2 may not be unconnected to multi-collinearity (Gujarati, 2003) between the independent variables i.e. LCPI (-1) and LCPI (-2). This implies that two successive CPIs have similar linear movement. This finding agrees with the extant literature that inflation does drive up building material prices (Anunobi, 1997, Ofoegbu, 1998, Ojimelekwe, 1999, Jagboro & Atigogo, 2000 and Jagboro & Owoeye, 2004 etc).

CONCLUSION AND RECOMMENDATION

Price level movement or inflation affects building material prices significantly. The Price level movement in the current quarter will impact significantly on building material prices up to two quarters thereafter. The government through its regulatory institutions must provide enabling environment that stabilize price level of consumer goods and building materials. Since the single largest proportion of the Nigerian CPI is composed of foods and consumer goods efforts must be made toward the sustainable development of the agricultural sector to produce abundant foods that reduces the price volatility. Government must also develop mining, manufacturing and transportation to improve price stability in the economy. Furthermore, effort must also be directed towards reducing importation of consumer goods and building material that expose both the CPI and building material prices in foreign exchange volatility.

TRAINING AND DEVELOPMENT OF BUILDING SURVEYORS IN MALAYSIA

Azlan Shah Ali[1] and Chen Jia Woon

[1]*Centre for Construction, Building and Urban Studies, Faculty of Built Environment, University of Malaya, 50603 Kuala Lumpur, Malaysia.*

ABSTRACT

The Building Surveyor (BS) is a qualified person who performs Building Control works and other activities related to construction which involves an organised preparatory process of physical development, supervision of construction quality and Physical conditions of the building. BS plays a vital role in the building industry, especially in developed countries such as the United Kingdom and Australia. However, the awareness on the importance of BSs in Malaysia is still low. Most of the BS graduates work in various fields after they have graduated. The competencies and professional level of BS graduates has always been debated by other professionals in the building industry. Hence, the study concentrates on the academic training of BS programme in Malaysian Universities in order to determine the efficiency of the learning outcomes. Additionally, the paper also focuses on the employment trend of BS graduates in Malaysia. Triangulation approach was used in the study. From the results, it could be concluded that BS are still demanded in Malaysian building industry even without the Building Surveyor Act. In terms of training for BSs in universities, the programme structures from 3 major universities were found to have covered comprehensively the aspects of building construction, technology, maintenance and legal requirements.

Keywords: training, building surveyor, Malaysia

INTRODUCTION

A Building Surveyor (BS) should be equipped with a thorough understanding of construction techniques, building materials, methods and technology skills simultaneously with knowledge on the building significance and building regulation (Dickinson, 1999). In Malaysia, a professional BS is an eligible person, by assessment and practice, and also a registered member of the Royal Institution of Surveyors Malaysia (RISM). The Building Surveyor service has started in Kuala Lumpur Municipal Council (KLMC) since 1950's. It was the British who first introduced the Building Control department which manages the building plan submissions and other related tasks with regards to new and existing construction works. Besides KLMC, there is another local authority which employes BS like Petaling Jaya City Council

[1] asafab@um.edu.my

(PJCC), Bentong Municipal Council (BMC) and Subang Jaya Municipal Council (SJMC) (Ahmad, 2003).

Although in developed countries such as in the United Kingdom (UK) and Australia the demand for BS graduates is great, so far it is not so in Malaysia due to some reasons. The profession of BS was constituted since year 1990, under the organization of RISM. Despite the long period of establishment, it is still in the process of getting recognition because the awareness level towards the significance of BS service is comparatively low. Only a few of BS graduates were employed in the government sector. On the other hand, most of the graduates are working in different fields such as property management, quantity surveying and construction sites.

Furthermore, there was an evidence of BS dating back to the 1860s in the UK with the formation of the RISM (Dickinson, 1999). Introduction of the 1961 syllabus on BS was started 10 years before BS were classed within the Royal Institution of Chartered Surveyors (RICS) as 'non-specialist members'. However, BS Division was then found to be necessary, formed by the RICS in 1973 to which the Council approved the designation *'Chartered Building Surveyor'* in 1975 (Dickinson, 1999).

DEVELOPMENT OF BUILDING SURVEYOR PROFESSION

United Kingdom was the first country which introduced BS profession. Only in United Kingdom, the BS will be given more authorised power if compared with other profession like Architect. The profession of BS had been further established and enhanced through the efforts of the Royal Institute of Chartered Surveyors (RICS). As a result, the job scope of BS were defined and identified. The area and scope of work of the BS in the context of project development and construction fields was acknowledged. Similarly, in Australia, BS are mainly involved in building control within the government agencies. Besides, BS carried out building dilapidation analysis for both new and historical buildings in private firms. In Hong Kong, BS profession is more recognised as compared to other Asian countries like Malaysia and Singapore. Comparatively, The Hong Kong Institute of Surveyors (HKIS) was already established earlier in the year 1985. There is a positive growth of the BS profession in getting recognition and acceptance as a vital position in the project development and construction industry. More than 20 years after the Building Surveying Division of RISM was formed, BS is still generally misunderstood by other professionals and the general public. BS is not just building sites and measurements. BS are also trained and qualified to advice on every aspect of the built environment and on the use of land (Dickinson, 1999). Dickinson (1999) further explained that BS is to make sure that buildings work as they were intended to, for the occupier, the landlord, the developer and the investor. Like in the UK, BS in Malaysia was originally under the General Practice Section, also known as Property Consultant Valuation Surveyors (PCVS). Even though the public had witnessed and benefitted from BS for decades in the UK, the role and skills of this profession was still not fully understood (Hashim, 1993). The public was still not aware of the existence of BS as a profession. It was even more surprising when there appeared to be a lack of understanding of the General Practice Surveyors (PCVS or BS) by some members, especially those of the other two sections (Yap, 1966).

CHALLENGES OF THE BUILDING SURVEYOR IN MALAYSIA

 ISBN: 978-1-84219-840-7 .

There are some issues and challenges faced by the BS profession in Malaysia. These are further discussed below:

i. Public Awareness and Recognition

In Malaysian context, there is lack of public awareness on the significance for establishment of BS profession in the construction industry. The position is not commercially introduced to the public. There is less in printed article about the profession mentioned in local newspaper media and it has leaded to ignorance among the public on its significance value. The public may not realized that they will get benefit from the BS profession because the surveyors will contribute their services in term of dilapidation and condition survey on new premises, old building and offering professional justification on the building's condition and its property value (Abd-Rashid et al., 2007).

ii. Acceptance of other professional bodies

Currently, the most challenging task for the establishment of BS profession in Malaysia is the process of gaining recognition and acceptance from other specialised professions like Architects, Engineers and Valuers. Continuous confrontation against the establishment of the BS profession gave a great impact towards the approval of the draft of BS Act. Those professional actually realise the significance of BS scope of work and accountability, but they worry to compete with the BS then loss their competitive business and specific area of expertise. It has contributed to the constant objection towards the approval and implementation of BS Act. Even those professional highlighted that it is not necessary to establish and endorse the BS profession with the reason that they are equally competent with their comparable knowledge and ability as the BS profession (Abd-Rashid et al., 2007). There are negative perspectives from certain parties who feel uncomfortable with the emergence of BS practice. The role of BS is actually not in competition with other professions; instead it complements and works in harmony with them. Therefore, each profession has their own role to play for the benefit of the industry. The society and the public should be the one who is supposed to gain the maximum benefit (Ahmad, 2003).

iii. No Specific Regulated Act

Building Surveyor Act been drafted and get approved since year 2007. Numerous amendment being done to make sure that the Act will get consent and recognition from other parties such as Architects and Engineers. Yet, until today, the teams of the BS division of RISM haven't gained any approval for the Act and hence it contributed to the retard of the approved regulation. The current evolution in Malaysia show that the BS profession will be included in Engineer or Technologist acts. When the Surveyor Act 1967 was first approved in Malaysia, BS profession was placed within the General Practice Group, within the same group with another 3 surveying professions which are Valuation, Housing and Planning, whereas Quantity Surveying formed a separate group under the same Act. Nonetheless, Land Surveying is under a different Act. The Surveyor Act was revised in the year 1972, 1973, 1974, and 1989. The revision was carried out without taking the existence and needs of BS services into consideration (Ahmad, 2003).

iv. Educational standard

Abd-Rashid et al (2007) proposed that the syllabus offered of the BS course is varied in the higher education institutions and/or local universities. It has created non-standardization of specific areas of expertise and responsibilities for a BS. There is

much effort being taken in ensuring the programme of study to reach up to an acceptable level. Only local institutions are found to comply with the RICS requirements while the rest are not especially in local private institutions.

In Malaysia, there is an agency known as Malaysian Qualifications Agency (MQA) which controls and monitors quality of new programmes introduced in universities. Besides, MQA is also responsible in monitoring and overseeing the quality assurance practices and accreditation of national higher education. In designing BS programme structure, MQA plays an important role in assuring the course fulfills the set criteria and standards. In fact, the guidelines for approval by Ministry of Higher Education set by the University are modified based on the guidelines provided by MQA.

v. Slow Response for Graduate Membership

Up to October 2006, there only 216 people who are registered as members of BS Division of RISM. In fact, the number of registered members is far less than the BS graduates, either from local or foreign institutions. Based on a research finding by Universiti Teknologi MARA (UiTM), there are a number of 535 BS graduates since the Diploma programme was introduced in 1999 and Bachelor Degree programme in 1995. The scenario showed that most of the graduates from local or private institutions are not registering themselves with the BS Division of RISM (Abd-Rashid et al., 2007). The slow response from the graduate students has slowed down the endorsement process of the BS Act. The students were do not enthusiastically engage in active advocacy for the adoption of standard practices and improvement of membership. Due to this lack of enthusiasm on the part of the existing members, it has led to the public, government and private sector not taking the profession more seriously than it currently is.

vi. Slow Response From Government

The BS profession has been approved by the Malaysia Public Service Department (JPA) in 1999. The service is placed under the Scheme in ENGINEERING Classification (J) and pay scales which are comparable with other professional services as recognised by government (Ahmad, 2003). However, Abd-Rashid et al. (2007) mention about the slow response from the government organizations to ensure all state and local authorities employ the BS qualified persons in their respective departments. The BS post is only being offered in 3 local authorities (municipal and city councils) within their departments. This scenario is due to the lack of awareness within the government sector itself about the important role of BS towards the local building and construction industries. This in turn is proving a big obstacle for the Building Surveyors to get recognition from the industry.

BUILDING SURVEYOR TRAINING IN MALAYSIAN UNIVERSITIES

There are three (3) public and one (1) private universities in Malaysia that offer BS programme at the Bachelor Degree level. They are University of Malaya (UM), University Science Malaysia (USM), UiTM and Twintech International University College of Technology (TIUCT). In this research, only BS syllabus for 2 universities has been discussed. In the latest UM BS programme syllabus, there are 30 courses, but with higher credit hours (106). Compared to the second constructed syllabus, nearly all of the subjects have been reviewed and redesigned. Besides Legal Studies

which remained almost the same, the other subjects have been re-constructed in order to fit with the requirement needed for a professional BS. The programme now concentrates mainly in Building Measurement & Analysis, Development Appraisal, Building Control & Design, Building Pathology & Dilapidation and Building Conservation Studies as the hours credited in these courses are considered as high (above 4 credits). These courses provide the core theory and practical knowledge that should be acquired by a BS today. Besides the main studies, the courses such as Environmental Science, Construction and Building Services are all crucial and they enhance the ability of a BS in both construction, maintenance and management field. Not forgetting the importance of subjects like Academic Project and Industrial Training that enable the undergraduate to be exposed to a more challenging research, ethic and practical experiences.

On the other hand, the USM introduced BS programme in 2009, twelve years after the programme has been set up in UM. The programme is offered in the School of Housing, Building & Planning. The programme structure for BS programme in USM is more or less similar with that of the UM syllabus.

RESEARCH METHODOLOGY

This research was designed using qualitative approach to study the employment trend of BS graduates. It also was used to get feedback from respondents on challenges faced by the BS profession and recommendations to overcome those challenges. The questionnaire contains 3 sections as following:

i. Section A: The respondent's particulars: - Closed ended question were asked in this section because the data can be easily analysed and eased the respondents in answering the questions.
ii. Section B: The respondent's perspective on BS profession:- Questions regarding challenges of BS profession using the Likert's scale which required the respondent to rate the significance of challenges ranging from 1 (least significant) to 5 (very significant).
iii. Section C: The respondent's opinion and recommendation on the BS profession: - This section used open-ended type of questions which did not limit the respondents to only choosing available alternatives as provided by the researcher. This was to obtain feedback with varied points of view.

DATA COLLECTION AND DISCUSSION

Table 1: Cross tabulation of gender of the respondent and the job title

Job Title	Gender	
	Male	Female
Contract Executive	0	2
Project Executive	3	3
Civil Engineer	2	0
Quantity Surveyor	2	10
Site Engineer	3	0
Property Valuer	0	1
Building Surveyor	1	1
Other	4	0
Total	15	17

The findings obtained were conformed to what Abd-Rashid et al (2007) mentioned earlier. From the responses received, there was a trend that indicated that BS graduates do not work as BS after they had graduated. Majority of them were working in different fields related to the construction industry. It was found that males normally work at site whereas females preferred to work in the office after they had graduated. Refer Table 1.

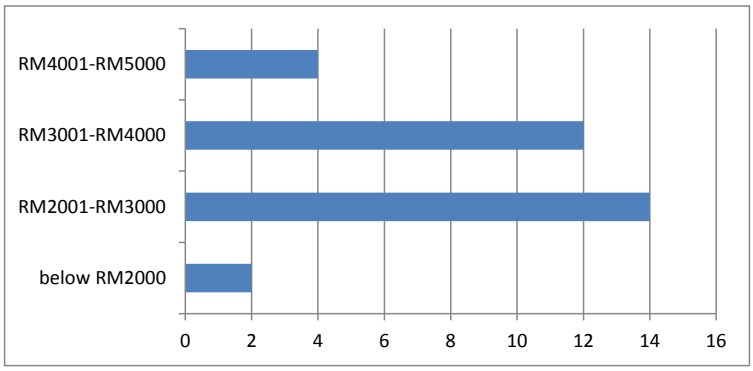

Figure 1: Salary Range for BS Graduates in Malaysia (n=32)

Figure 1 shows the salary range for the BS graduates. There were 14 respondents who answered this question, of which 43.8% who receive a monthly salary paid within the range of RM2001 to RM300, followed by 12 respondent in the range of RM3001 to RM4000 (37.5%), 4 respondents were paid RM4001 to RM5000 (12.5%) and 2 respondents were working with the salary range below RM2000 (6.3%).

Table 2: Cross tabulation of year of graduation of the respondents and the salary paid

Monthly Salary Paid	Year of Graduation of Respondent					
	2003	2004	2005	2006	2007	2008
below RM2000	0	1	0	1	0	0
RM2001-RM3000	1	1	1	0	3	8
RM3001-RM4000	2	1	0	1	2	6
RM4001-RM5000	1	0	1	0	0	2
Total	4	3	2	2	5	16

Table 2 shows the cross tabulation of year of graduation of the respondent with their monthly salary paid. From the table above, monthly salary paid for the respondents who graduated in year 2003 in the range of RM2001 to RM5000. The figure indicates that BS graduates are still able to perform very well in their working field because the salary paid is very attractive as compared with salary scale of other surveying graduates such as quantity and land surveyors.

Respondents were also asked on their response about the importance of BS in Malaysian construction industry. More than 70% of the respondents agreed that BS plays an important role in the Malaysian construction industry. The same respondents agreed that there was no other specific profession that was responsible for guiding builders on the building regulations. They further explained that BS is the person who ensures all the building control regulations are complied with during the planning and construction works of all kinds of buildings and of most property for instance extensions, refurbishments, renovations, conversions etc.

Moreover, they agreed that BS will resolve any uncertainties regarding building regulations matters. BS also undertakes site visits throughout the construction stages to ensure that the procedures are being carried out properly and in accordance with the regulations. One of the respondents had mentioned that buildings need safety and security auditing which can be carried out by BS. On the other hand, 6 respondents (18.8%) did not agree that BS is important in Malaysia. The respondents felt so because there are not many BS jobs being offered in Malaysia in the construction market.

Table 3: Responses on challenges of establishment of BS profession

Challenges	Mean	Standard Deviation	Ranking
No specific Act or regulation	3.84	1.439	1
Slow response from Government	3.78	1.263	2
Acceptance of other professional bodies	3.63	1.212	3
Entitlement of BS	3.59	1.316	4
Public awareness and recognition	3.47	1.565	5
Educational standard	3.34	.937	6
Slow response from graduate students	3.16	.847	7

Respondents further asked about the most important challenges for the establishment of the BS profession in Malaysia. Table 3 indicates the ranking on the responses received. No specific Act or regulation is the most significant challenge faced, for the establishment of BS profession in Malaysia. The results were reconfirmed as Dickinson (1999) mentioned that there will be an increase of job opportunity among the building surveyors once the BS Act is regulated. Ahmad (2003) had also pointed out that BS had struggled for years to lobby for the enactment of the BS Act since 1970s. Without the Act, BS cannot register as a professional body under the Ministry of Finance. This has restricted the BS to perform in their profession in the building control and performance field.

The second highest ranked challenge is slow response from government. It is in accordance with the view of Abd-Rashid et al. (2007) that the government is slow in ensuring BS profession is positioned at a vantage within the respective government departments. According to Ahmad (2003), the Surveyor Act 1967 was firstly approved in 1960s and later revised in the 1970s to 1980s. Yet, the revision never took into consideration of the BS professional needs. In the late 2000, the Ministry had approved and mentioned the BS Act in the Parliament but there was no immediate action taken therefore the application was left pending.

Acceptance of other professional bodies ranked number 3 out of 7 challenges. This reflects the statement made by Ahmad (2003) and Abd-Rashid et al. (2007). In the current scenario, there is a continuous argument from other professional bodies especially the Architects and Engineers. With the establishment of the BS profession, there will be someone who controls, oversees and limits their profession. They are afraid that BS will monopolise the construction market and they would lose their business and specific scope of services.

From the survey conducted, 84.4% agreed that BS can stand together with other professional job/post level in Malaysian Construction Industry now and also in the future. The respondent had mentioned that it will be possible provided Malaysian construction industry is made aware of the importance and scope of BS in building

construction industry. Moreover, BS is involved from pre-construction stage until post construction stage. BS has knowledge in planning, construction and design, combined with practical mind-set and IT skills. Some of the respondents stated that BS can stand together with other professions once it recognized by the government and with a specified Act to regulate it. Some respondents argue that BS is a vital profession in order to ensure and enhance the quality of construction in Malaysia. There will be different professions and each profession should have their own specification and specialization of work and BS is the main person to deal with building pathology and condition survey. In the absence of BS Act, there are no specific job scopes that can be claimed under the BS domain. In contrast, other professions have their respective Act to protect them.

The survey also attempted to find out the ways in which the BS profession in the Malaysian Construction industry can be enhanced and creation of awareness of the BS's role. The feedbacks received show the majority of the respondents pointed out that the government should play an important role in promoting BS profession to public or other professional bodies. The government should create more job opportunities for graduated BS in construction industry so as to make known the existence of BS. Some of the respondents proposed that starting BS course in more universities all over Malaysia will help. Moreover, the government should take immediate action in passing the BS Act. The BS Act will enable the BS in Malaysia to register themselves as a professional body under the Ministry of Finance. With the registered license, they can perform as consultants in the field of construction. . The BS Act will eventually protect the public interest by lowering the probability of building defects, abandoned projects and low building functional utility. In addition, the BS graduates should prove themselves in the construction industry and let people know that BS student multi-faceted personnel in construction management and building management. . They must prove that they are able to carry out their job and as competently as other professionals.

In the aspect of training, both universities UM and USM have used the same guidelines to design their programme structure. Generally, almost all subjects included in the course are the same with the latest syllabus in University of Malaya, except some differences in the subject titles.

CONCLUSION

They are 6 challenges being identified in the literature reviewed, faced by BS and the most significant challenge was that no specific act was passed for the profession. The study also identified that the possibility to overcome this issue was by applying a holistic approach that combined the efforts of the government, public and the BS graduates themselves to promote and pass the BS Act as soon as possible. Although in absence of the BS Act, there is still a demand for BS in the Malaysian construction industry. One of the indicators showed that the BS graduates are still able to get an attractive salary which is equivalent to other professionals such as engineers and architects.

University of Helsinki, PO Box 4, 00014 Helsinki, Finland

Email: eeva-maija.puheloinen@helsinki.fi; ari.ekroos@helsinki.fi

Abstract:
Climate change is one of the biggest challenges facing mankind today. With the intention of mitigating climate change, a few countries have passed climate change acts. This paper compares four climate change acts in Europe: in United Kingdom, Scotland, Austria, and France. Most of the acts set a target of greenhouse gas emissions reduction for 2050. There are similarities with setting periodic or annual targets, monitoring the progress in relation to emissions reduction, and establishing a climate change committee. But the focus in the acts differs. The UK and Scottish Acts are both framework acts and consist of more of planning mechanisms than of substantive provisions of law, whereas the French Act is clear in regard to the measures on how to mitigate climate change. In conclusion, all the acts represent the national need, or the national situation at the moment, in relation to climate change mitigation. This study shows that there can be different approaches to climate change acts and the UK model is not the only choice. Nevertheless, it remains to be seen what kind of results these climate change acts can deliver.

Keywords:
Climate change act, climate change, climate law, comparative law.

1 Introduction

Climate change is one of the biggest challenges facing mankind today. With the intention of mitigating climate change, a few countries have passed climate change acts: United Kingdom (UK) and Scotland separately, Austria, France, the South Korea, Mexico, and Australia at least have legislation that can be called climate change acts. And many countries are considering of making one. What do these climate change acts in force comprise of? What kinds of targets do they set? How binding are the commitments? What is the timeline with the acts? How are they enforced? These questions are studied in this paper.

The paper is a comparative law study on climate change acts in the European Union member states that have passed climate change acts: the UK, and Scotland separately, Austria, and France. It is justified to look at the Scottish legislation since the climate acts in force in Europe are very limited and the Scottish Climate Change Act differs from the UK Climate Change Act. The comparison is limited to binding legislation; there are a number of different strategies and policies, in governmental level, about climate change mitigation but their comparison is much broader topic than this paper,

and the focus of that comparison is more in politics rather than in law. Furthermore, there is a lot of national sectoral legislation concerning climate change related issues, such as emissions trading, renewable energy promotion, and energy efficiency, but the focus in this paper is in the target-setting "general" climate change acts. In conclusion, the paper gives insight into solutions used in these countries concerning climate change mitigation.

This paper will first discuss the question of climate change mitigation on international level, European Union (EU) level, and development in some European countries. Comparison between climate change acts in selected European countries will follow then; the comparison is divided into subsections concerning important and common elements in these acts. The paper closes with linkages to the broader discussion of climate change mitigation and adaptation.

2 Development in Europe

2.1 International level

The international background to climate change mitigation is set in the United Nations Framework Convention on Climate Change (UNFCCC) adopted in 1992 (United Nations 1992). Currently, 195 parties have ratified the convention. The Kyoto Protocol to the convention sets binding targets for 37 industrialized countries and the European community to reduce their overall emissions of greenhouse gases by at least 5 % below 1990 levels in the five-year period 2008 to 2012 (United Nations 1998). The future of the global convention is still undecided, though negotiations agreed in Durban have started.

2.2 EU-level

The European Union has taken action in order to mitigate climate change: the so-called EU 20-20-20 targets consist of 1) decreasing greenhouse gas emissions by 20 % below 1990 levels, 2) improving energy efficiency by 20 %, and 3) promoting the use of energy produced with renewable sources up to 20 % of the energy consumption. The targets are set to be accomplished by 2020.

To set the 20-20-20 targets into binding legislation, the EU climate and energy package was introduced in 2009. Firstly, the package includes a revision of the Emissions Trading System (ETS). From 2013 to 2020 the ETS cuts emissions by 21 % from the 2005 level, annually by 1.74 %, among sectors it is applied to. Secondly, the Effort Sharing Decision limits emissions from non-ETS sectors, such as transport, housing, agriculture and waste. The overall EU target for emission reduction in the non-ETS sector is 10 % below the 2005 level which is divided into binding national targets. Thirdly, by the so called RES-directive, the use of energy from renewable sources is raised to 20 % of overall EU energy consumption by the year 2020, a target which is also divided into binding national targets. And finally, the package includes a legal framework to promote the development and safe use of carbon capture and storage (CCS) (EU 2009).

Furthermore, in trying to boost the international climate change negotiations, the EU has made a conditional offer to raise its target for 2020 emissions reduction from 20% to

30% if “a global and comprehensive agreement” is reached. Additionally, the EU aims at 80 to 95% reduction in EU emissions by 2050 compared to 1990 and suggests this target for other developed counties, too (EU 2009). For clarity, it must be stated that this target is not legally binding.

2.3 Member States

The UK has led the way in putting the climate change targets into binding legislation: the UK Climate Change Act was passed in 2008 and has been an example for later climate change acts. The following year Scotland passed a more detailed act to be applied in addition to the UK Act: the Climate Change (Scotland) Act 2009. Understandably, the Scottish Act looks very similar to the UK Act. In France, the regulation concerning climate change has been developed as part of the revision of the environmental legislation since 2007; the two-staged reform is called Grenelle 1 (2009) ja Grenelle 2 (2010). The most important output of Grenelle 1, in climate change point of view, is an “environmental program act” (Loi n° 2009‑967 du 3 août 2009 de programmation relative à la mise en oeuvre du Grenelle de l'environnement), that coordinates legislation. The first part of this act embraces climate change mitigation and can be referred to as the French Climate Change Act. The latest climate change act has been passed in 2011 in Austria, Bundesgesetz zur Einhaltung von Höchstmengen von Treibhausgasemissionen und zur Erarbeitung von wirksamen Maßnahmen zum Klimaschutz (Klimaschutzgesetz - KSG).

In summary, in the EU, there are four climate change acts in force: the UK Climate Change Act, the Scotland Climate Change Act, the French Climate Change Act (Loi n° 2009‑967 du 3 août 2009 de programmation relative à la mise en oeuvre du Grenelle de l'environnement, part 1, and the Austrian Climate Change Act (Klimaschutzgesetz). Additionally, Slovenia is well on the way of passing a climate change act but apparently the draft Climate Change Act has not yet been adopted by the National Assembly (Slovenia 2011).

2.4 Finland

The Finnish Government has drawn up a report of climate and energy politics aiming at low carbon future. In the report, Finland is envisioned as cutting emissions at least by 80% from the 1990 level, as part of international cooperation (Finland 2009). The 2011 Government platform calls for a study about whether passing a climate act is needed (Finland 2011). The study, which includes some outlines of possible act, has just been published (Ekroos and Warsta 2012).

3 Comparison between the Climate Change Acts in Europe

3.1 Overview of the climate change acts in this study

The UK Climate Change Act is extensive and generates procedures related to climate change mitigation. The act sets a target for the reduction of greenhouse gas emissions by 2050 and introduces a system of carbon budgeting to meet the target (Part 1). Additionally, a Committee on Climate Change is established as an expert body (Part 2). The Act enables the establishment of trading schemes in order to reduce greenhouse gas emissions (Part 3) and schemes for producing less domestic waste and promote

recycling, and their financial incentives (Part 5). Additionally, there are provisions about adaptation to climate change (Part 4).

The Scotland Climate Change Act sets targets for the reduction of greenhouse gas emissions: a target for 2050 and an interim target for 2020 as well as provides for annual targets (Part 1). There are provision on the Scottish Committee on Climate Change (Part 2), reporting (Part 3), and adaptation to climate change (Part 5) as there are in the UK Act. Additionally, the act sets duties to public bodies and stipulates about land use, energy efficiency, and waste reduction (Part 5).

Like the UK and Scotland Acts, the Austrian Climate Act is a framework act by its nature. The act has provisions about negotiations for drawing up the measures to share the emissions reduction target (section 3), national climate committee and advisory board (sections 4 and 5), and progress report (section 6). However, this act does not stipulate new national obligations but focuses on clearer distribution of liability between the federation and the states, and creating framework for negotiations to ensure the planning and implementation of climate politics. Nevertheless, the act is surprisingly short with its 9 sections and two annexes.

The French Climate Change Act encompasses general framework for planning and substantive provisions of law concerning in the same context. The act sets general objectives for climate change mitigation (section 2). Additionally, the act has many substantive provisions of law which aim at mitigating climate change; there are provisions about reduction of energy consumption (sections 3-6 and 18-21), spatial planning (section 7), transport (sections 10 ‑ 17), and sustainable development related research (section 22). These provisions together with the legislation in Grenelle 2 package aim at greenhouse gas emissions reductions in non-ETS sectors, which is regulated separately.

3.2 Target for 2050

Of the four climate change acts subject in this comparison, three include a target for 2050: the UK, Scotland and France. Both the UK and Scotland Climate Change Acts set a target of at least 80% lower carbon account for 2050 than in 1990. In this connection, the carbon account refers to actual greenhouse gas emissions of that year/time period plus appropriate credits and debits. The UK Climate Act enables amending the 2050 target under strict conditions, such as significant development in scientific knowledge about climate change or European or international law or policy. The French Climate Change Act stipulates the target for 2050 in a slightly different way: the greenhouse gas emissions must be limited into one fourth of the 1990 level by year 2050 that is a 75% reduction. Additionally, the 2050 target is stated numerically in the French Act, too: annual emissions must be reduced to less than 140 million tons of carbon dioxide equivalent. The Austrian Act does not set a target for 2050.

Moreover, the Scottish Act sets an interim target for year 2020 which limits the emissions account to 42% compared to the baseline year 1990, and interim target includes a possibility of modification of the percentage under strict conditions. The UK Act also sets an objective for 2020, although not as highlighted as in the Scottish Act, that is 26% lower than in 1990. The French Act repeats the EU-wide binding target of

 ISBN: 978-1-84219-840-7 .

20% emissions reduction for year 2020, unless the EU tightens the objective up to 30%. A little bit differently, the Austrian Act repeats the EU-objective for emissions reduction in non-ETS sectors which national target set for Austria is a 16% reduction compared to year 2005. Naturally, these numbers are not comparable as such since the baseline year is different.

The targets for 2050 in the three acts are quite similar and in line with EU-vision of the long-term development towards a low-carbon economy; the French target is not stated as strongly as the UK and Scotland targets which are in a highlighted position in the acts. The Scottish interim target is clearly more ambitious. Austria has left the targets to be set later after negotiations. This way the Austrian Act differs from the other acts.

3.3 Timeline in planning

There are different approaches in dividing the each long-term target in question into shorter periods. The UK sets for five-year-periods ("budgetary periods") an amount for the net UK carbon account (the "carbon budget"). The budgetary periods including year 2020 or year 2050 must be set to meet the 2020 or 2050 targets. The carbon budgets until 2022 have been set in 2009 and for later periods every 12 years before the beginning of that period.

In Scotland, the planning is annual and linear; the target is set for every year from 2010 to 2050 and every succeeding year the target is not higher than the year before. The annual targets for years from 2010 to 2022 must have been set in 2010; respectively, years 2023–2027 in 2011, years 2028–2032 in 2016, years 2033–2037 in 2021, years 2038–2042 in 2026, years 2043–2047 in 2031, and years 2048–2050 in 2036. The annual targets must be set in consistency with the 2050 target and the interim target. The Scottish Ministers must set the targets by order that is in secondary legislation. The target-setting process and modifying the annual targets are stipulated thoroughly in the Act.

In the Annex of the Austrian Act, the maximum levels of greenhouse gas emissions are shared to sectors for the commitment period 2008 to 2012. The sharing after 2012 must be negotiated separately, in compliance with the provisions set for the negotiations in the Act. The planning is set for commitment periods, the first which is from 2013 to 2020. The negotiations begin one month after a proposal from the relevant Minister and must be completed within nine months before the beginning of the period. The outcome of the negotiations will be binding and the measures must be implemented promptly.

In the UK and Scottish acts, the annual or period based targets must be set well, at least 12 years, ahead whereas the Austrian 9 months is significantly shorter time. This has to do with predictability. Furthermore, the Austrian planning is not set as far for the future as the UK/Scotland but leaves the continuation after 2020 open. The French Act requires annual average emissions reduction target of 3% but does not set other general periodic targets than the target for 2050. In this perspective, the French approach differs clearly from the other climate change acts.

 ISBN: 978-1-84219-840-7 .

3.4 Measures to reach the target

In UK, the act sets the Secretary of State an obligation to prepare proposals and policies to reduce the greenhouse gas emissions to meet the carbon budgets (section 13). The nature of the proposals and policies is left open. However, the act confers powers to relevant national authority to establish trading schemes relating to greenhouse gas emissions (section 44); in particular, activities of energy consumption, use of energy-consuming material, waste management of energy-consuming material, and "the production or supply of anything whose subsequent use directly causes or contributes to greenhouse gas emissions". The last definition is broad.

The Scottish Act requires the public bodies to act in a way that contributes to the reaching of the targets (2050, interim and annual targets) (section 44). Moreover, the act confers powers to make provision about energy efficiency of buildings, both non-domestic buildings and living accommodation, including provision enabling council tax discounts (part 5, chapter 3).

The French Climate Change Act (section 2) names as primary measures to mitigate climate change lowering the energy consumption of buildings and reducing greenhouse gas emissions from the transport and energy production. The cost of greenhouse gas emissions is directed to be incorporated in the pricing of goods and services by means of improving consumer information, adopting new legislation, extending ETS to new sectors, and auctioning allowances. Also, taxation measures are presented in relation to what is called "climate-energy". Additionally, as possible measures are mentioned restrictions for import from countries that refuse to bear their responsibility in climate change, economic incentive schemes, and public funding. Moreover, sections 3 to 22 stipulate sectoral targets in mitigating climate change, in the fields of energy consumption, spatial planning, and transport. For instance, the energy consumption of all new public buildings is limited to 50 kWh/m2 after the end of 2010 (section 4).

The Austrian Act refers to energy efficiency, promotion of renewable energy production, energy efficiency in the building sector, integration of climate change in spatial planning, mobility management, waste prevention, protection and enhancement of natural carbon sinks, and economic incentives as possible fields to be taken into account in the negotiations for setting the measures.

The UK, Scotland and Austrian acts only refer to possible sectors which can be subject to measures in order to reach the targets set in the acts (2050, interim and periodic/annual targets). In the French Act, the measures are shown in the act itself, making the legislation integrated and transparent.

3.5 Monitoring

The UK Act requires annual statements on the UK emissions and additionally final statements for budgetary periods, and a final statement for 2050 (sections 16, 18 and 20); the statements will be presented to the Parliament. Also, the Scottish Act calls for reporting to Parliament on annual basis (part 3). In the UK and Scotland acts, there are detailed provisions on how the reporting must be presented. Additionally, the Austrian act provides for an annual report (Fortschrittsbericht) about the progress of greenhouse gas emissions; the report must be structured by sectors (section 6). Moreover, the

 ISBN: 978-1-84219-840-7 .

French Act calls for annual reports to the Parliament on the implementation of the commitments under the Act and their economic impacts.

In short, annual statements to Parliament are required in all the acts.

3.6 Climate change committee or other

In the UK, a Committee on Climate Change has been established. It advices on level of 2050 target, advices in connection with carbon budgets, advices on emissions from international aviation and international shipping, reports on progress, and provides advice or other assistance on request (sections 33-38 of the UK Act).The Committee consists of a chair plus 5 to 8 members. Schedule 1 to the UK Act stipulates the operating of the Committee. Additionally, the Scottish Act enables the establishment of a Scottish Climate Change Committee which advices on annual targets, reports on progress towards targets, and provide advice or other assistance (part 2). The composition of the Committee is the same as in UK.

According to section 4 of the Austrian Act, a national climate committee (Nationales Klimaschutzkomitee) should be established. The committee evaluates the fundamental questions of Austrian climate politics. In particular, the committee should take part in drafting the climate strategy for commitment periods, with which strategy the foundation is set for emissions reduction targets to be shared to sectors. Additionally, the committee should draft long-term scenarios for promoting energy efficiency and energy produced with renewable energy sources, and development towards a low-carbon economy. Moreover, the Austrian Act requires setting of a national “climate advisory council” (Nationaler Klimaschutzbeirat) that gives the committee advice (section 5). However, the French Act does not stipulate about a climate change committee or other advisory organ. This does not necessarily mean that such a committee has not been established.

The climate committees in the acts play an important role, in particular in setting the annual or periodic targets. Additionally, for instance in the UK Act, in relation to amending the 2050 target, the advice of the Committee on Climate Change must be taken into account (section 3).

4 Conclusions

The four European climate change acts approach very differently the same challenge of climate change mitigation. Still, there are many similarities, too. Three out of four acts set a target for 2050 for reduction of greenhouse gas emissions. There are provisions on setting periodic or annual targets, monitoring the progress in relation to emissions reduction, and establishing a climate change committee. But the focus in the acts differs.

The UK and Scotland Climate Change Acts set a clear target for 2050 and a system of setting periodic or annual targets to reach the 2050 target. The amending of these targets is strictly regulated in the acts; it is more difficult to amend these targets than to amend other legislation. This seems to be an interesting special arrangement. The UK and Scottish Acts are both framework acts and consist of more of planning mechanisms than of substantive provisions of law.

As for the French Act, of the 22 sections related to climate change in the act, only one (section 2, greenhouse gas emissions reduction target etc.) stipulates of the same kind of core topics as the other climate change acts in this study. The other 21 sections are substantive provisions of law and set sectoral targets in various topics under climate change mitigation. The French Act seems clear in regard to the measures on how to mitigate climate change. There are elements and targets of sectoral legislation put together in the same act, and therefore, the French Act together with Grenelle 2 can be characterized as transparently integrating legislation.

The Austrian Climate Change Act can be seen as an example of a federal state's characteristics of liability distribution which is in the focus of the Act. Otherwise the Austrian Act could be characterized as lacking ambition since the target and the measures have been shifted to be dealt in separate negotiations.

In conclusion, all the acts represent the national need, or the national situation at the moment, in relation to climate change mitigation. On one hand, it is hard to evaluate these acts separately from other related legislation. On the other hand, comparing the whole climate change legislations in different countries would be very complicated. In addition, "climate change act" as a concept is unclear. This study shows that there can be different approaches to climate change acts and the UK model is not the only choice. Still, the UK model is strong and sure to have an influence on future national climate change acts. It has to be kept in mind that from various legal reasons, e.g., in Finland, because of constitutional restrictions, many aspects of the UK model cannot be copied as such. Nevertheless, it remains to be seen what kind of results these climate change acts can deliver.

Abstract:
Global warming and its impact on our environment, society, economies and security is one of the fundamental concerns of our time. In response, the United Kingdom government has put in place a legally binding target of an 80% reduction in greenhouse gas emissions on 1990 levels by 2050. The United Kingdom will need to achieve a tenfold expansion of energy supply from renewable sources by 2020 to meet its share of the European Union renewable energy target. The marine and coastal environment's renewable energy potential in Britain is high. It is estimated that it has 50% of the tidal energy, 35% of wave and 40% of wind resources in the European Union. Use of geothermal resources using heat pump technology is the least evolved sector, but in 2010 contributed to 0.7 TWh of energy and it is believed that non domestic heat pumps could contribute up to 22 TWh by 2020. In the Southwest of England, Poole Harbour has been recognised as a potential, highly predictable source of tidal and heat energy. Local groups are embarking on a feasibility study for harnessing this energy for the benefit of the community. The purpose of this article is to examine the potential conflict of interest between the laudable aims of promoting the use of renewable energy and of safeguarding ecosystems and their biodiversity. Using Poole Harbour as a case study, it will consider the environmental and economic costs and benefits of a Community Renewable Energy project (the Poole Tidal Energy Partnership) in the context of an area subject to a number of statutory and non-statutory designations to protect nationally and internationally important habitats and species. The paper identifies key environmental legislation, including spatial planning law and policy, which will facilitate exploring whether there is potential for reconciling what may be perceived as competing objectives for sustainable development.

1 Introduction

The global commitment to renewable energy and energy security stems from the application of Bentham's utilitarian philosophical perspective of "the greatest good for the greatest number" (Presnell, 1996 and Bentham, 1789). By securing energy obtained from naturally occurring elements within the biosphere, e.g. from the sun, the wind and the oceans, we are attempting to prevent further deterioration of natural and cultural resources. In doing so, we are aiming to pass on to our descendants a better world, or at least in as good condition as the one we ourselves inherited (Weiss, 1984). This perspective was supported by Brundtland who stated that future development crucially depends on the long term availability of energy "in increasing quantities from sources that are dependable, safe and environmentally sound (Brundtland Report, Chapter 7, 1987). However the report recognised as well, that harmful ecological transformation may occur as a consequence of the technology required to harvest natural sources, citing as an example the problems encountered in hydropower where hydrodams block paths for migrating fish (Brundtland Report, 1987).

The precautionary principle 15 of the Rio Declaration 1992 (Rio Declaration) addresses this danger by suggesting a positive obligation on regulators to act to prevent the materialisation of health or environmental risks, despite the lack of scientific certainty over the nature or extent of the ecological transformation. The existence of scientific uncertainty should become a trigger for precautionary measures, and for 'reversing the onus of proof' so that proponents, rather than regulators, bear the burden of demonstrating that there is no need for regulatory action (Peel, 2004).

The European Union (EU) and the United Kingdom (UK) have adopted the precautionary principle as one of their guiding environmental policies. The UK Climate Change Policy introduced this principle with legal, economic and technological enabling mechanisms to reduce green house gases in the UK (Jordan and O'Riordan, 1995). Following recommendations from the UK Committee on Climate Change, the Department of Energy and Climate Change (DECC) has put forward policies to achieve 30% of electricity generation from renewable sources by 2020 (DECC, 2012), aiming further than the EU 15% target. To meet these targets the DECC has indicated that 7.5% needs to be delivered from local sources (DECC, 2012). In response to this, local authorities are embarking on their own strategies to achieve these objectives.

One such strategy has been approved in the southwest of England between Dorset County Council, the Borough of Poole Council and Bournemouth Borough Council. This strategy is known as the *'Renewable Energy Strategy to 2020'* (Dorset Energy Partnership (DEP), 2012) and aims to harness viable renewable energy resources to maximise local economic, environmental and community benefits (DEP, 2012).

Poole Harbour is the one of largest natural saltwater harbours in the UK. It represents a highly predictable tidal and heat energy potential that has prompted local interest in investigating the possibility of harnessing it for the benefit of the area through community schemes (Cooling, 2011). At the same time, Poole Harbour has a variety of marine, freshwater and terrestrial habitats which, together with surrounding Areas of Outstanding Natural Beauty, are subject to a number of statutory and non-statutory designations. The proposal to harness marine renewable energy from Poole Harbour will provide an insight into the different challenges faced by Community Renewable Energy(CRE) schemes.

 ISBN: 978-1-84219-840-7 .

These include ecological, legal, economic and planning issues that need to be factored in order to achieve climate change mitigation without loss of biodiversity.

2. Community Renewable Energy projects

Alternative methods of energy production are available on both large and small scales (Miller, 2006). However, it is considered that small scale, community based renewable energy schemes are better able to meet the precautionary principle (Poladitis et al., 2006). It has also been proposed that small scale schemes are more likely to fit in with the doctrine of sustainable development, as local interested parties will use their understanding of local needs and their natural environment to propose sensible precautionary measures (Dincer, 2000). From their agreeance with the precautionary principle and the principle of sustainable development, it can be argued that CRE projects are an innovative and successful way to supply energy to homes and businesses on a small scale with a range of associated benefits for local people and ecosystems (Rogers et al., 2012). Although this concept is not particularly new, with a few communities beginning to adopt this ethos from the 1970s (Walker, 2008), it is in more recent years that interest has risen in CRE as a way to produce energy with much reduced environmental cost. This wider interest, together with the advances in technology to generate secure and financially viable renewable energy, has led to a significant increase in the number of community driven projects (Department of Trade and Industry, 2000). The aim is to provide locally based, renewable, secure energy supplies with an emphasis on community participation, ownership and a green ethos (Rogers et al., 2012).

As each community and locality differs from the last, there is no set framework or protocol for CRE projects (Rogers et al., 2008). Each one is unique, according to site, community vision and choice of technology (Shackley and Green, 2005). Nevertheless, common features amongst these schemes are: the existence of a set of values shared by all involved and that, according to research on public perceptions, local communities find these projects desirable (Rogers et al., 2008).

2.1. The Poole Tidal Energy Partnership: background and technical detail

The Poole Tidal Energy Partnership (PTEP) was formed on 4th November 2011 in response to local policies on renewable energy (Email from Hadley 2012). This partnership, with participants from the Borough of Poole, Transition Town Poole and Bournemouth University, combines local knowledge, community representation and technical expertise to form a single organisation focussed upon driving forwards the vision of a local, secure and green energy supply. PTEP's aim is to provide renewable energy at affordable prices to local residents whilst encouraging a high degree of community participation in the project.

PTEP initially proposed to employ underwater turbine technology to power a water source heat pump system that could provide heat energy to residents living within the immediate area (Stanford, 2012). However the tidal current prototype generator was ruled out because the depth of the water in Poole Harbour (1 – 5 m) did not meet the requirements for cost-effective power generation (20-30m) (Turnpenny et al., 1995 and Dorset Energy Partnership (DEP) 2012). It was then suggested that a Water Source Heat Pump (WSHP), without the turbine technology, might be the most viable technology for

this harbour. This could be implemented either as a closed or open loop system (Email from Hadley 27 July 2012) and both are currently under consideration.

A closed loop system (see figure 1) employs a fluid (food grade glycol and water mix) that circulates within a submerged coil of flexible pipework which absorbs energy from the surrounding water (Forsen, 2005). A sufficient depth is required to prevent freezing around the pipework and any damage from passing marine traffic (Kensa Engineering Ltd, 2009).

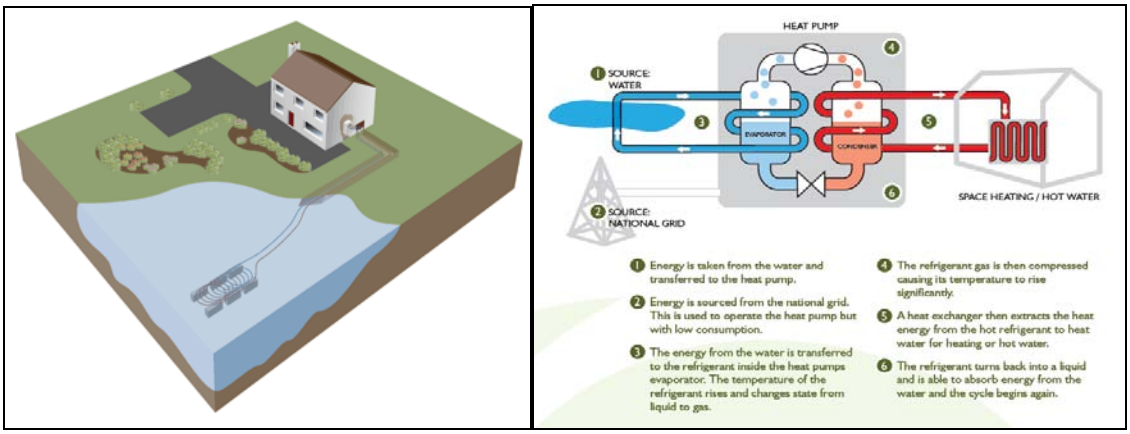

Figure 1: Closed Loop water source heat pump (Source: Forsen, M. 2005.)

An Open source system (see figure 2) draws in water out of the harbour, passing it through the heat pump and then discharges it back into the harbour (Forsen, 2005). This brings into consideration associated issues of corrosion, filtration, extraction and possible freezing within the heat exchanger (Forsen, 2005).

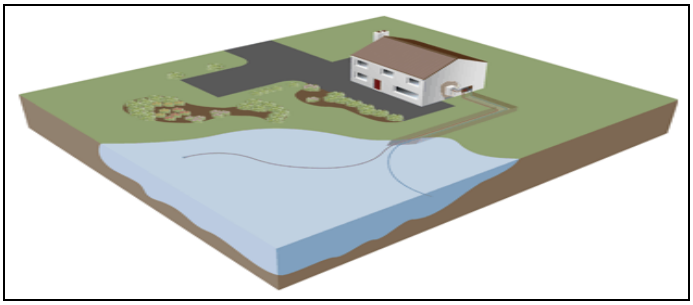

Figure 2: Open Loop heat pump (Source: Forsen, M. 2005)

3. Economics

As both a fundamental concern to both society and the principle of sustainable development, it is important for the scheme at Poole Harbour (along with all CREs) to consider the economic benefits and disadvantages of development. The UK Renewable Energy Roadmap sets out actions to help meet the above mentioned targets to generate energy from renewable sources and focuses on eight different technologies which “have

either the greatest potential to help the UK meet the 2020 target in a cost effective and sustainable way, or offer great potential for the decades that follow" (DECC, 2011a).

The eight technologies identified are: onshore wind, offshore wind, marine energy, biomass electricity, biomass heat, ground and air source heat pumps, and renewable transport (DECC 2011). Government Ministers believe that the UK has "the best wind, wave and tidal resources in Europe" (DECC, 2011a). Significant opportunities exist for the UK to make the most of its island geography and harness the power of its coastline in the production of low carbon energy.

In November 2011, the Government launched the Renewable Heat Incentive (RHI) scheme to provide "financial support to non-domestic renewable heat generators" (DECC 2011b). This seeks to provide a twenty year income stream to those who install a system covered under the scheme with the aim of making renewable heat an attractive commercial option. Renewable heat is simply any heat generated from a renewable source and will include the use of ground and water (marine) source heat pumps.

Gazo et al (2011) identify heat pumps as being the largest worldwide application for direct use geothermal energy, with worldwide utilisation in 2010 of 214,780TJ/yr (59,632 GWh/yr). The Government has set aside £680m for use between 2011 and 2015 to fund the RHI scheme (DECC, 2011b), with the amount payable to each scheme being dependent on the amount of heat generated. Non-domestic heat generation would include schools, businesses, hospitals and district heating schemes.

An international example of non-domestic, direct use, marine-source heat pumps can be seen off the coast of Sundsvall, Sweden, where the organisation Permobil AB. has laid 5000m of looped piping on the sea bed. This pipework links to four 30kW heat pumps, sufficient to provide heating for 3,300m2 of the organisation's facilities with only an occasional need for "top-up" power (NIBE, 2012).

In the UK, the National Trust is currently working with Bangor University to investigate the possibility of using marine-source heat pump technology to reduce the energy costs of the mansion Plas Newydd on the Isle of Anglesy (Jones, 2011). The proposed installation of a large scale closed loop system on the bed of the Menai Straits off the coastline has the potential to save £65,000 p.a. (Guardian, 2012).

Within Poole Harbour the opportunities for direct use geothermal energy production are currently being explored, through the use of marine-source heat pumps in a number of locations, to provide heat to a number of sites, which may be eligible for government support under the RHI.

The potential locations that have been identified are as follows:

a) Sterte Court – (Poole Housing Partnership flats)
b) Upton Country Park - (tearooms rather than main house)
c) Hamworthy Schools – (Carter Community, Hamworthy First and Hamworthy Middle)
d) Rockley Park (caravan park and communal buildings)
e) Hamworthy Library (potentially this and other local buildings)
f) RNLI headquarters.
g) Poole Harbour Redevelopment area

It is proposed that these sites may be suitable for the direct use geothermal energy produced via either closed or open loop water source heat pump systems.

Whilst there are planning and environmental concerns regarding such development in Poole Harbour, economic considerations must feature strongly in any analysis regarding the viability of such a project.

A series of evaluation methods could be employed to appraise the merits of the proposed Poole Harbour scheme. Cost/Benefit analysis incorporating Net Present Value (NPV); Internal Rate of Return (IRR) or Payback analysis could be employed to assess financial viability. When using discounted cash flow techniques (DCF) such as NPV and IRR, future cash flows are discounted (using an appropriate discount rate) to present value. This allows comparison between alternative options and those producing a positive NPV classed as financially viable.

The first issue would be in determining an appropriate discount rate, as previous large scale energy projects (such as evaluations of the Severn Tidal Barrage scheme or proposed nuclear development within the UK) have produced wide ranging forecasts resulting from assumptions over the discount rate (Ginige et al., 2011). The standard Government approach in the UK is to use 3.5% (HM Treasury 2011) for evaluating projects requiring central government funding. However, for projects requiring private finance, example 10% discount rates have been applied (DECC 2010) but in reality, private investor's own cost of capital would determine overall viability.

A typical NPV analysis may offset discounted monetised costs and benefits against each other to provide the 'net' result. The question arises of the monetised costs to be included in such analysis.
Kavanaugh et al (1995) cited Gazo et al (2011) breaks down the cost of a direct use geothermal heat Pump system. The capital costs, which for many renewable (or low carbon) energy projects are the most expensive element, consist of:

a) Ground loop = up to 34% of cost
b) Heat pump = up to 30% of cost
c) Indoor installation = up to 21% of cost
d) Ductwork = up to 15% of cost
e) Pumps = up to 7% of cost

Gazo et al (2011) suggest that although capital costs are higher than most other forms of conventional heating, low operational costs result. In addition, the type of system used can affect the capital costs. A vertical closed-loop system will require pipework to be drilled underground and therefore becomes far more expensive than a horizontal loop system (which requires no drilling). However, although a closed loop horizontal system may have 50% lower capital costs, Gazo et al (2011) explain that "for large installations, it may be impossible to find adequate areas for the installation".

A site such as Poole Harbour, given the size and flat nature of the harbour bed may be suitable for horizontal loop systems and therefore allow localised heat generation to be gained at a reduced capital cost, alongside the benefits of lower operational cost.

 ISBN: 978-1-84219-840-7 .

In addition to capital, operational and maintenance costs, the level of compensation for the habitat affected will potentially need to be factored into the calculations. As an indication of this cost, compensatory habitat was provided for at £72,000/ha during the Feasibility Study for the Severn Barrage (DECC 2010). Furthermore, costs of mitigating undesirable environmental effects may need to be considered.

These costs could be offset against key monetised benefits, which may include the "avoided capital investment in other technologies and avoided running costs of other technologies" (DECC 2010) or the potential savings in energy costs, which Gazo et al (2011) report as being between 30% to 60% for domestic systems. Further economies of scale may result for larger scale non-domestic systems.

Energy cost savings will in part be affected by the efficiency of the heat pumps. Gazo and Lind (2010) explain that this efficiency is measured by the Coefficient of Performance (COP). The COP measures the amount of energy produced by the heat pump in heating mode, divided by the amount of energy required to drive the heat pump (Gazo and Lind 2010).

$$COP = \frac{\text{Heat Capacity (kW)}}{\text{Electric Power Input (kW)}}$$

The heat pumps to be used in Poole Harbour are expected to have a very efficient COP of 5:1.

When evaluating such a project purely from an investor perspective, giving consideration only to direct, monetary values, Woodruff (2007 p.18) states that "a project is financially viable when a project's revenues exceeds its costs". However, Woodruff (2007) contrasts this with an economic approach, where both direct and indirect, monetary and non-monetary costs and benefits are considered. Clearly, economic analysis from a societal perspective provides a much wider scope of factors to be considered and may lead to contrasting results. Using this economic approach, Woodruff (2007) advises "the project with the greatest net benefits should be chosen among all technologically feasible options for providing electricity….".

Considering an economic approach to the evaluation of renewable energy projects, key non-monetised costs and benefits may need to be incorporated into the analysis. However the difficulty here is that these are difficult to quantify. Air or noise pollution during construction may be a consideration but perhaps the greatest non-monetised cost is the potential effects on the ecosystem within the harbour and beyond. The impact on and valuation of ecosystem services is a consideration which must form part of the appraisal of future energy projects in general and especially in a project where the site is as significant as Poole Harbour. These non-monetised costs may be countered by non-monetised benefits, such as macroeconomic benefits for the UK as a whole (DECC 2010) through the use of renewable energy and contribution towards EU energy targets. However, whether on balance this leads to a net benefit, and to whom, is the subject of

 ISBN: 978-1-84219-840-7 .

much debate, and is dependent on the valuation of these non-monetised costs and benefits.

4. Poole Harbour Ecology

As noted, Poole Harbour is an area of significant environmental importance. In order to appreciate the impact that the PTEP project in Poole Harbour, an understanding of the geological features and ecological importance of the area is imperative.

Poole Bay is a drowned valley (ria) that was formed at the end of the last ice age. The bay is an estuary formed from a number of rivers, the largest of which is the River Frome, and is surrounded by shallow creeks and islands (Humphreys and May,2005). Poole Harbour, located to the west of Poole Bay, is one of the largest natural harbours in the UK, and which has a shallow water depth of approximately 1 to 5 metres. The depth of the bay is between 5 and 20m and has a gradually shelving sandy bottom (Turnpenny et al., 1995). Its micro-tidal regime results in the retention of a significant body of water throughout the tidal cycle; with a spring tide range of 1.8m and a neap tide range of 0.6m. Twice a day, between "30,400 to 45,000 cubic metres of water enters and leaves Poole Harbour", offering huge potential for the implementation of marine renewable projects (Cooling,2011). Another relevant feature of the Harbour is the unique inter-tidal habitats which have resulted in the area being internationally important for populations of breeding and migratory bird species (Herbert et al., 2010).

The Harbour is a heavily utilised and managed site covering an area of approximately 3600ha (Humphreys and May 2005), with the densely populated north side of the harbour serving the town of Poole (Poole Harbour Aquatic Management Plan 2011). There are local management schemes that aim to keep disturbance in the area to a minimum, particularly in bird sensitive areas between Studland Bay, at the entrance of the Harbour, and Keysworth Point, to the west (Poole Harbour Aquatic Management Plan, 2011). The Poole Harbour Aquatic Management Plan, overseen by the Poole Harbour Steering Group, advocates zoning, as shown in figure 3, to "assist in the reduction of disturbance to environmentally sensitive areas". The plan's main objective is "to promote the safe and sustainable use of Poole Harbour" whilst balancing the competing demands of user groups (Poole Harbour Aquatic Management Plan, 2011).

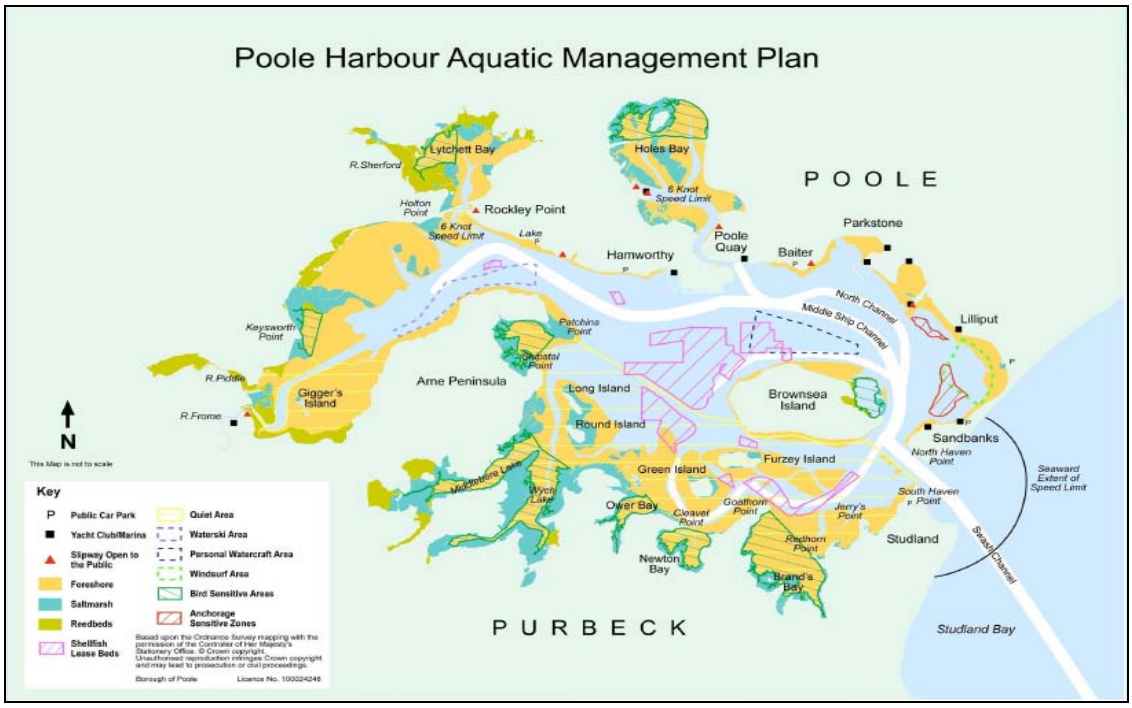

Figure 3: Map Showing Poole Harbour, Recreational activity zones (source: Poole Harbour Aquatic Management Plan, 2011)

Due to the variety of important marine, freshwater and terrestrial habitats of conservation interest located within Poole Harbour, the area is subject to a number of statutory and non-statutory designations (Marine Management Organisation (MMO), 2012). As an internationally acclaimed site for avifauna, supporting populations of birdlife year round, the intertidal mudflats, reed beds and salt marshes bordering the harbour are important feeding and breeding sites for these species (Natural England 2010). The harbour supports internationally significant populations of black-tailed godwit (*Limosa limosa)* and large numbers of dunlin (*Calidris alpine)*, redshank (*Tringa tetanus)* and curlew (*Numenius arquata)* (Durrell et al., 2006). In addition, a number of islands are located within the harbour: Brownsea Island and lagoon, Long Island, Furzey Island, Green Island and Round Island. They all provide habitat for a diversity of coastal and terrestrial species including the avocet (*Recurvirostra avosetta*), spoonbill (*Platalea leucorodia*) and red squirrel (*Sciurus vulgaris*) (Langston, 2003). Furthermore, adjacent to the harbour are several nature reserves; Upton Heath, Arne, and Holton Heath, which are highly regarded nationally and internationally for supporting healthy populations of rare native reptiles, birds, insects and plant life (Natural England 2010).

Anthropogenic activities in the marine environment within the harbour include heavy freight and bulk movements, tourism and leisure activities, and fishing. Many of these contribute to the presence of invasive species (Pearce, 2012). Furthermore, dredging of one shipping channel to facilitate access to the harbour takes place on a regular basis (Poole Harbour Commissioners Draft Management Plan 2011). These activities are already a constant threat to its conditions and features (Natural England 2010).

The impacts of novel structures required by any renewable energy project into marine environments are largely unknown (Polagye et al., 2011). However, in the case of the

 ISBN: 978-1-84219-840-7 .

PTEP proposal it is possible to forecast some degree of disruption to species movements and migrations, alteration of benthic habitats, contamination from paints/lubricants, injury through collision of being struck by the energy generating technology, alteration of currents/water movement, increased noise through installation and operation of technology, and the cumulative impacts of all of these stressors (Polagye et al., 2011) in addition to the existing ones. Therefore, very careful planning would be required to avoid detrimental consequences to this site which is supporting nationally and internationally protected species and habitats (Liley and Clarke, 2003).

5. Environmental Legislation

The overarching legislation in the UK that regulates development on land and in marine environments, including the activities of renewable energy projects, is the spatial planning legislation. The Town and Country Planning Act 1990 and the Marine and Coastal Access Act 2009 are the principal Acts for terrestrial and marine areas respectively. Spatial planning legislation has two main statutory levers: forward policy and programme making and the control and shaping of development proposals through the granting or refusal of planning permissions (Crawford and French, 2008) or licences, in the case of marine developments. For the Poole Tidal Energy Partnership project to be able to proceed, it must acquire consent under spatial planning legislation from the appropriate authority whose determination will be guided by spatial development plans and related policy documents. (This issue will be discussed further in section 6).

Additionally, due to its recognised ecological importance, any development in Poole Harbour needs to take into consideration certain international conventions, European and UK marine and nature conservation laws, as well as water quality legislation. This results in a complex environmental legal framework that gives several layers of protection, sometimes from different points of views, to the same site. The most relevant legislation with regard to Poole Harbour will be discussed below.

5.1 Nature Conservation Legislation

At an international level the UK is a signatory to the Convention for the Protection of the marine Environment of the North-East Atlantic, 1992 (OSPAR Convention). According to Art. 1 of the Convention, Poole Harbour and the sea adjacent to it comes within the remit of Region II Greater North Sea. Therefore, under Art. 2(1)(a) UK has a duty ´to take all possible steps to prevent and eliminate pollution and shall take the necessary measures to protect the maritime area against the adverse effects of human activities so as to safeguard human health and to conserve marine ecosystems and, when practicable, restore marine areas which have been adversely affected`. To this end the UK is required to adopt measures to tackle pollution and prevent degradation of this marine and costal environment. An expression of the application of these measures at local level is seen in the Poole Harbour Aquatic Management Plan created by the Poole Harbour Steering Group (Poole Harbour Aquatic Management Plan, 2011).

The UK also ratified the Convention on Wetlands of International Importance, 1971 (Ramsar Convention) in 1976. This convention imposes a general duty to promote the conservation of wetlands and waterfowl. ‘Wetlands’ are defined as ‘areas of marsh, with water that is static or flowing, fresh, brackish or salt, including areas of marine water

 ISBN: 978-1-84219-840-7 .

whose depth does not exceed 6m'. Due to their ecological importance, parts of Poole Harbour were designated a Ramsar wetland site in 1999 (JNCC 2008).

In England all terrestrial areas included within listed Ramsar sites are currently Sites of Special Scientific Interest (SSSI).They are legally protected under the Wildlife and Countryside Act 1981 as amended. Poole Harbour was first designated as a SSSI in 1964 under the National Parks and Access to the Countryside Act 1949 12, 13 & 14 GEO. 6. CH. 97 (English Nature.1990) to protect its intertidal and coastal habitats. It is protected under the provisions of Part II of the Wildlife and countryside Act 1981 SI 1982 No. 1217 (C 39) as substituted by Schedule 9 of the Countryside and Rights of Way Act 2000. 2000 c. 37 (CRoWA 2000). As a result all public bodies are required to take reasonable and consistent steps with the proper exercise of their functions, in order to protect the conservation features of the SSSI. The legislation also places legal obligations on owners and occupiers of the land within the SSSI and also to any person in relation to activities that may cause damage to its special features or recklessly disturb any animal of special interest.

Section 28 of Wildlife and Countryside Act 1981 as substituted by Schedule 9 of the CRoWA 2000, further outlines the responsibilities and obligations of public and statutory bodies when carrying out activities or authorised works within a SSSI. There is a list of operations and activities likely to damage the features of special interest of Poole Harbour SSSI, which can be obtained from natural England. The owner or occupier of land within a SSSI can only allow these activities to occur on their land with the consent of Natural England.

At European level the oldest nature conservation legislation is the Council Directive 2009/147/EC on the Conservation of wild birds (EU Birds Directive). Member States designate Special Protection Areas (SPA) to conserve the birds listed in Annex 1 of the Directive, including migratory birds. The SPAs are also classed as Natura 2000 sites, which form part of a European network of protected sites.

In 1999 parts of Poole Harbour were designated SPA due to the internationally important assemblages of waterfowl and populations of certain regularly occurring resident and migratory species (Humphreys and May,2005). These species are protected by Art. 4 of the Council Directive 79/409/EEC on the Conservation of wild birds (the first Birds Directive consolidated later in the one mentioned above) and are listed in Annex II of Council Directive 92/43/EEC on the Conservation on natural habitats and of wild fauna and flora (EU Habitats Directive) and the relevant site assessment.

Under the UK Conservation of Habitats and Species Regulations 2010-SI 2010 No 490, the EU Habitats Directive forms the basis for the protection and management of the SPA (see figure 4). The part of the SPA which covers the intertidal zone of the Harbour is referred to as a European Marine Site (EMS). Any activity classed as a high risk will require additional management measures to avoid deterioration and disturbance in line with the obligations under Art 6(2) of the EU Habitats Directive (European Commission, 2000).

 ISBN: 978-1-84219-840-7 .

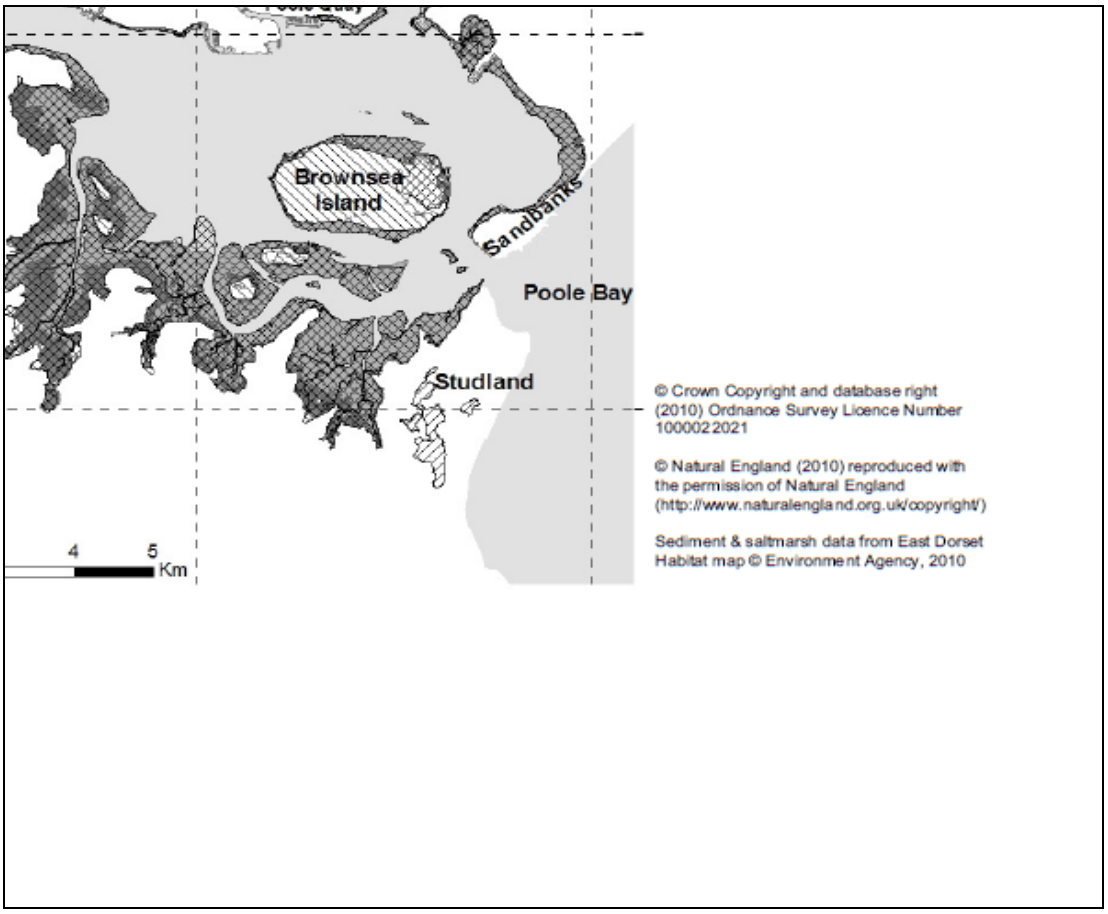

Figure 4: Map of Poole Harbour showing SSSI and SPA boundaries (source Poole Harbour Aquatic Management Plan 2011)

As discussed above, the Birds Directive and Habitats Directive impose a duty on Member States to protect SPAs and is directly applicable to Poole Harbour. However, whilst providing protection for SPAs, the latter also provides Member States with the power to permit development on protected sites in certain circumstances. Article 6(4) of the Habitats Directive states that a project may go ahead if there are no alternatives and there is an overriding public interest, including socio-economic factors. Furthermore, the guidelines to the Directive state that whilst development on a protected site, particularly one with vulnerable species, is not ideal in cases where public safety or immediate environmental protection are a necessity, plans or projects may still go ahead (Kramer, 2009).

In some proposed plans these guidelines have been subjected to significant criticism because they seem to override the nature conservation issues in favour of the socio-economic benefits. However, there are examples of opposite outcomes with regard to projects with potential detrimental impact on the environment. On the one hand, in 2003 the Dibben Bay Appeal showed that nature conservation interest were given a higher status than the economic and social interests because the proposed cargo terminal in Dibden Bay would damage the integrity of the Solent and Southampton Water Ramsar site, the SPA and other surrounding protected areas. On the other hand, in the feasibility study for a tidal energy project in the Severn Estuary, the government gave more

 ISBN: 978-1-84219-840-7 .

importance to economic and the energy generation potential over the detrimental environmental impacts to the nature conservation sites. The final reason for the plan not being implemented was that the scheme did not appear cost effective (Ginige et al., 2011).

Another important aspect within the discussion of nature conservation law is the concept of cumulative impacts. This refers to the consequence of more than one direct or indirect impacts acting together, resulting in an outcome difficult to predict, with indirect consequences manifesting in unexpected places and after of a period time (Barrow, 2006). Different laws take this concept into consideration.

Council Directive 85/337/EEC as amended by 95/11/EC and 2003/35/EC on the assessment of the effects of certain public and private projects on the environment (EU EIA Directive) establishes the circumstances when an Environmental Impact Assessment (EIA) is required. The Habitats Directive Art.6(3) also includes a requirement to conduct another appropriate assessment if the plan or project, either individually or in combination with other plans or projects, has the potential to significantly affect the integrity of a Natura 2000 site. It is suggested that the provisions found in these Directives provide clear instructions about what must be considered, referring specifically to the requirement to use best available techniques, the need to identify all potential impacts (including cumulative ones), and the most effective mitigation measures must also be discussed (Kramer, 2009). However, despite the provision in these Directives about the considerations required to be included in the assessments (Kramer, 2009), it is apparent that there is confusion on the part of EIA practitioners regarding the definition of cumulative impacts and their specific requirements (Masden et al., 2010). Particular uncertainty arises within the UK Town and Country Planning (Environmental Impact Assessment) Regulations 1999 SI 1999 No239, where cumulative impacts are given different definitions. For example, schedule 3, section 1a, refers to them as those impacts which occur having regard, amongst other things, to the size of the development, while section 1b as those cumulating with other developments. These definitions lead one to infer that cumulative impacts are to be considered as impacts which occur across developments. However, schedule 4 part 1, which deals with information required in the environmental statements, defines these potential consequences as “a description of the likely significant effects of the development on the environment, which should cover the cumulative effects of the development”, implying that they are impacts which accumulate within the life of the project(Cooper and Sheate, 2002). Such confusion as to what needs to be considered as a cumulative impact of a development could significantly affect an EIA undertaken on Poole Harbour. Depending on the interpretation of the practitioner, could result in potential impacts going unnoticed.

Another essential concept in nature conservation law is compensatory measures. Should it be decided that a renewable energy development in Poole Harbour should be approved under grounds of “imperative reasons of overriding public interest” (IROPI), per Art.6(4) of the Habitats Directive. It would then have to satisfy the conditions set out in the Directive’s guidance notes and compensatory measures must be implemented. This means that the UK would be required to provide compensatory habitat to protect the integrity of the Natura 2000 network (Ginige et al., 2010). However, the effectiveness of creating compensatory habitats in Poole Harbour can be questioned on the grounds that alternative habitats may not be sufficient to maintain species survival. Poole Harbour was designated

 ISBN: 978-1-84219-840-7 .

because it supports species that are rare or unique in themselves. In order to comply with the Habitats Directive, compensation must be of equal or higher quality than the habitat it is replacing (MMO, 2011). Obviously, this is no easy feat and many studies have been undertaken to understand the implications of habitat compensation. The best example of habitat mitigation in the UK was the creation of intertidal mud flats in Teesmouth (Evans 1998, cited by Atkinson, 2003) at Seal Sands through managed retreat. Here, it was found that, for the most part colonies could be re-established at new sites but there was a time lag of around three years (Atkinson 2003). This is relevant to Poole Harbour's distinct environment which provides important habitats for vulnerable birdlife. Whilst there have been studies where habitat compensation in the United States has proved successful, the same rules are not as easily applicable in Poole Harbour, where intertidal habitats are far more diverse in terms of sediment sizes and tidal ranges (Atkinson et al., 2001). Therefore, it would make a difficult enterprise to secure compensatory habitats of an equal or better standard as required under the Directive (Humphreys and May 2005).

This leads the case for creating replacement habitat prior to starting development of the old site (Atkinson et al., 2001), thus embracing the precautionary principle and ensuring that there will be successful populations of the misplaced species. It is stated in the guidelines to the Habitats Directive that "a site should not be irreversibly affected by a project before the compensation is indeed in place" (European Commission, 2007), allowing for exceptions if it takes a long time to establish a new replacement habitat. As previously identified, there can be a time lag of up to three years to fully establish a working ecosystem.

If a project received approval, presumably there would be pressure to implement it as soon as possible. Therefore, it may be difficult to ensure that compensatory habitats are able to fulfil expectations. If it was the case that a scheme was in operation prior to the creation of compensatory habitat, the Member State would be responsible to provide "extra compensation" (that the compensation must be additional in relation to the Natura 2000 network to which the Member State should have contributed in conformity with the Directives) (European Commission, 2007 pg 13). Added to this, the guidelines of the Directive suggest that if all these options cannot be fulfilled and development would affect rare species, the "zero option" (withdrawal of the project) must be considered (European Commission, 2007).

Another area of UK legislation relevant to a proposed renewable energy project in Poole Harbour is the Marine & Coastal Access Act 2009 (MCAA). It contains important requirements designed to promote and maintain biodiversity in British waters, combining the protection of the marine environment with human health, prevention of interference with legitimate uses of the sea, (section 69) and a strong emphasis on supporting renewable energy (s12) and marine economic zones (s116).

Besides all the above, it must be mentioned that much of the Harbour also lies within the Dorset Area of Outstanding Natural Beauty (AONB), which was designated in 1959 under the National Parks and Access to the Countryside Act 1949 to conserve and enhance the natural beauty of the site (Dorset Area of Outstanding Natural Beauty 2012). In addition, Poole Harbour is a site of archaeological heritage interest that was recognised in 2003, when it was identified as a Wetland of National Importance by English Heritage

 ISBN: 978-1-84219-840-7 .

in accordance with the National Heritage Act 2002 (Poole Harbour Aquatic Management Plan 2011).

5.2 Water pollution and quality

In the UK the Environment Agency (EA) is the statutory body responsible for managing the water resources, their quality and pollution control by virtue of s.2 of the Environtment Act 1995 (EA 1995). Water pollution and water quality is regulated by the Water Resources Act 1991 (WRA) as amended by the Environment Act 1995, the Water Industry Act 1991 and the Water Industry Act 1999; together they provide the main regulatory controls in England and Wales.

The Environment Agency is charged with preventing deterioration of water quality and seeking its improvement; it has a duty to promote the conservation and enhancement of the water environment (inland and coastal waters). As well as pollution control, the Agency's responsibilities include water resource management, planning and conservation, flood defence, forecasting and warning, abstraction licences, fisheries and in some areas navigation. It also has certain duties in relation to promoting conservation; amenity and recreational facilities. Besides the EA's regulatory functions at national level, its duties also embrace the UK's obligation under the Council Directive 2000/60/EC establishing a framework for Community action in the field of water policy (EU Water Framework Directive or WFD).

The WFD set, for the first time, legal standards for monitoring and reporting the health of water bodies throughout Europe (Bell and McGillivray, 2008). The ultimate goal of the legislation is that all European water bodies assessed should meet 'good ecological and chemical status' by 2015, or must have management actively working to achieve this per Art.4.1 WFD. The Directive, and the resulting domestic law (The Water Environment (Water Framework Directive) (England and Wales) Regulations 2003-S. I. 2003 No. 3242), applies to all terrestrial and groundwater including transitional (estuarine) and coastal waters (up to 1 nautical mile from the coast). WFD assessments are applicable to the waters in both estuaries and harbours, meaning that new developments should be able to demonstrate, prior to consent, that no detrimental impacts to the water quality could be reasonably foreseen by the proposed activity (MMO, 2012).

At a national level water management obligation under WFD is undertaken through River Basin Management Plans, which allows splitting into small catchments areas. (Article 4 WFD) The WFD takes a significant step towards integration of water protection and looks beyond immediate human interest in the protection of water considering living things dependant on water autonomously of human interest(Scott,2009). Environmental Protection:European law and Governance. Oxford Universty Press, Oxford) Standardised methodologies and assessment tools are available to ensure consistency in monitoring (Bell and McGillivray, 2008). However, with the division of larger water bodies into catchments, there is much potential for conflicts between catchment objectives and land use and water quality (Moss, 2004).

The varied management objectives of the rivers discharging into Poole Harbour (Poole Harbour Aquatic Management Plan 2011) may ultimately lead to alterations in the anthropogenic inputs which reach the harbour, thus impacting on primary production

(Scanlan et al., 2007). As a heavily modified water body, Poole Harbour should be seeking to achieve 'good ecological potential', ultimately meaning no further declines in water quality (Uriarte and Borja 2009). Specific considerations for the Poole Harbour PTEP proposal, under the WFD, should include avoidance of any activity that would permanently or periodically increase the rates of erosion, sedimentation or turbidity (Poole Harbour Aquatic Management Plan 2011). Furthermore, it must be sensitive to the protection and promotion of salt marsh areas -as the decline of these has been linked to increased heavy metal presence, e.g. cadmium, in the harbour waters- (Hübner et al., 2010). Finally, a full assessment of the likely impacts to both the biotic and abiotic components of this environment should be undertaken (MMO 2012).

The requirements for the safe installation of a closed or open loop water source heat pump system (WSHC) vary according to the different technology and risk involved. These requirements are given by the EA in *Environmental good practice guide for ground source heating and cooling,* (Environment Agency, 2011).

The closed loop heat pump systems do not currently necessitate any form of permision from the EA if located on a privately owned piece of land. But if the closed loop scheme was to be put into, or adjacent to, a watercourse it may require a flood defense consent. Whilst the majority of close loops schemes are installed and operated with no harmful effect on the environment, owners and installers should bare in mind that they are liable for any adverse effects that the scheme may cause (Environment Agency, 2011). The potential types of risk of a closed WSHC system are discharge of a polluting substance (e.g. escape of circulating fluid) and changes of temperature in the water. In the first scenario, if the scheme leads to discharge of a polluting substance to controlled waters (including ground water), the drilling contractor, the installer, the owner or operator may be liable for prosecution under Environmental Permitting (England and Wales) Regulations 2010 (EPR 2010) regulations 38(1) and 12(1). In the second scenario, if the discharge or removal of heat by the system interferes with the environment features, actions might be brought against the operator of the scheme under the UK Law of Nuisance and the EU Environmental Liability Directive.

The open loop WSHC system involves abstraction of water for heating and cooling purposes and will require an abstraction licence from the EA if the quantity abstracted is more than $20m^3/d$ in any 24 hour period ((Environment Agency, June 2010. *Managing Water Abstraction*. Environment Agency. Bristol). The water that emerges from the heat exchanger will most likely have changed its temperature. It will usually be warmer (in a cooling scheme) or colder (in a heating scheme) than the original water. This thermally changed water will be discharged into a surface water body (as defined in s.104 of the WRA 1991), in our case Poole Harbour, a natural water body. In order to obtain the required EA discharge consent permit, via the Environmental Permiting Regulations 2010, the resulting water must not contain polluting chemicals, the temperature change must be less than 8ºC, the outlet temperature must not exceed 25ºC and the discharge must be to the same water body from which the water was abstracted. Furthermore, the discharge ‘must not be made into fresh water within 500 metres upstream from a designated shellfish water, European site, Ramsar site, SSSI or any body of water identified as containing a protected species or within 100m of a wild life site’ (pg. 24).

 ISBN: 978-1-84219-840-7 .

For a tidal water site the distance of 500m for the discharge to take place means 'in any direction' to the nearest boundary of any of the sites mentioned above (pursuant of Chapter 4 of the EPR 2010 see Environment Agency, 2010).

5.3 Environmental Liability Directive

The EU's Directive 2004/35/CE of the European Parliament and of the Council on environmental liability with regard to the prevention and remedying of environmental damage (Consolidated 01/05/2006) (Environmental Liability Directive or ELD) was transposed into UK legislation belatedly through the Environmental Damage (Prevention and Remediation) Regulations 2009 (SI 2009/153, as amended by SI 2009/3275) (EDR 2009).

A key purpose of the regulation is to make the operator of an activity solely responsible for putting right any environmental damage, or threat of environmental damage (and the costs of so doing), caused by his activities – i.e. application of the polluter pays principle. The operator will also be liable for any remedial costs incurred by the enforcing authority unless he can demonstrate that the environmental damage (or threat of environmental damage) was caused by a third party (Bergkamp, 2002)

Environmental damage according to the EDR 2009 is damage caused by an activity listed in schedule 2 to: protected species or natural habitats listed in the EU Birds Directive and the EU Habitats Directive– mainly those on Natura 2000 sites – and also to those on SSSI notified under the Wildlife and Countryside Act 1981.

EDR 2009 schedule 1 details the threshold of damage for: species and habitats on and off SSSIs; surface water or ground water, including any adverse effect on the environment of surface or groundwaters resulting in the deterioration of status as defined in the WFD, whether ecological, chemical or quantitative; land where it relates to contamination which brings about a significant risk to human health or contamination through the introduction of organisms or micro-organisms. The activities causing damage are listed in schedule 2 and include: permitted installations; waste management operations; mining waste; discharges requiring authorisation; water abstraction and impoundment; manufacture, use, storage etc of dangerous substances; plant protection products and biocidal products; transport of dangerous goods; contained or deliberate release of genetically modified organisms; and transboundary shipment of waste.

In the case of environmental damage to protected species, natural habitats or SSSIs, the EDR 2009 also covers damage caused by any other activity if the operator either intended to cause the damage or was negligent as to whether damage would be caused (part 1 section 5).

It excludes from its scope any environmental damage that took place before the EDR 2009 came into force (part 1 section 8 EDR 2009); environmental damage caused by oil pollution, in which liability or compensation falls within the scope of relevant international conventions such as the 1992 Protocol to the Convention on Civil Liability for Oil Pollution Damage; damage caused by radioactivity from an activity covered by the Treaty establishing the European Atomic Energy Community; environmental damage as a result of an 'act of terrorism', 'natural disasters' such as hurricanes or exceptional

flooding (but regular seasonal flooding is not excluded) , and damage caused by commercial sea fishing carried out in compliance with the Common Fisheries Policy.

The EDR 2009 also exempts damage to water caused by new modifications to the physical characteristics of a surface water body, alteration to the level of a body of groundwater, and deterioration from high to good status of a body of surface water resulting from new sustainable human development activities.

Under the EDR 2009 s20 (1) if relevant harm has occurred, the operator responsible must take remedial measures. If the primary remediation does not fully restore the damaged site, 'complementary' remediation must be undertaken, on the site or elsewhere, to compensate for that fact (EDR 2009 schedule 4, Part1, section 5) . 'Compensatory' remediation will also be required to make up for the interim losses during the period until the primary and complementary measures take effect. Guidance is given on the choice of measures and what is appropriate for complementary or compensatory remediation where direct equivalence is not possible. For conservation sites, the effect is that if a site is destroyed or cannot be wholly restored, then alternative or supplementary measures must be taken to provide the same overall conservation value, albeit not necessarily a direct equivalent to what has been lost, and before the damaged site is fully restored or a substitute provided, interim measures must be taken to make up for what is temporarily lost. Here, although the responsibility is on the operator to propose and undertake the remedial action, it is still the relevant 'competent authority' that determines what must actually be done (Reid, 2011).

To sum up, there are different levels of environmental legislation that protect Poole Harbour's biodiversity from the threat of antropogenic activities. This patchwork quilt of laws aim to conserve specifically: the wetland, intertidal and coastal habitats, resident and migratory wild birds, the natural beauty of the site, its archaeological relevance, the marine ecosystem and the water body itself autonomously of human interests. At the core of these laws is the need to promote a healthy marine ecosystem alongside minimal restrictions of human activities. This is achieved through site and species designations, regulations of the works and activities carried out in the Harbour, by placing legal obligations to those carrying activities within the site and by requiring EIA where there is risk of harm to the protected characteristics of the site. Furthermore, the law establishes a system of liability and compensation measures in the event of potential and actual damage to the environment.

These laws are indicative of the international and national recognition given to Poole Harbour's ecological features. They acknowledge the impact that human activities have on the natural environment and the need to promote sustainable interaction. Nevertheless, the discussion above demonstrates that, in certain provisions, the law seems to give adequate protection to the environment, whilst in others is restricting its effectiveness . It is suggested that this incongruency stems from the attempt to engage with what seem to be conflicting agendas: the safeguard of the environment on the one hand and antropogenic activities on the other, including the promotion of renewable energy. Although the latter results from the attempt to mitigate climate change, it carries the burden of this tension.

 ISBN: 978-1-84219-840-7 .

6. Spatial Planning

It is important to recognise that a key aspect to the implementation of any development project is the understanding of the legal framework, plans and policies for the control or management of development. (Moore, V. 2010) The merits or otherwise of a proposal will be examined, assessed, having regard to policies and plans, and determined by the granting or refusal of consent. In the context of coastal or marine works, the two main types of development consent required are:

1. planning permission for infrastructure to the boundary jurisdiction of the Local Planning Authority (generally above the Mean Low Water Mark (MLWM)) under the Town and Country Planning Act 1990 and
2. A Marine Licence for works below Mean High Water Springs (MHWS) under the Marine and Coastal Access Act 2009.

The two systems work independently of each other and are administered by Local Planning Authorities and the Marine Management Organisation (MMO) respectively. There is, however, a reciprocal system of consultation on development proposals. Applications for development will be determined in accordance with the Local Plan of the Local Planning Authority in the case of land-based development and in accordance with the relevant Marine Plan in the case of in and off-shore development. In locations where Marine Plans have yet to be produced, in the interim, direction on licensing decisions will be given by the (MPS) Marine Policy Statement.

Focusing on the in-shore development of the Poole Harbour project, the construction, alteration or improvement of any works either in or over the sea or on or under the sea bed (including off-shore generating stations with a capacity between 1 and 100 megawatts) requires a marine licence. Generating stations of a greater capacity are deemed to be national significant infrastructure projects and are subject to a different system of consent under the Planning Act 2008.

6.1 Stakeholder Engagement

Environmental management (and decision making) is as much about managing human activities as managing land and water, therefore requiring the effective engagement of all stakeholders (including government agencies, NGOs, the business community and the general public) in the process of information gathering and policy making. Engagement and participation engenders a sense of ownership of information and policymaking resulting in a common understanding of issues and a negotiated learning process. In the United Kingdom, as in many countries, part of the political agenda for improving governance at national and local level is the promotion of community capacity building across a range of policy areas including spatial planning. Participation is an integral part of Strategic Environmental Assessment (SEA) Directive 2001/42/EC and EIA Directive and in many countries, including the United Kingdom, participation is a mandatory requirement for all planning decisions.(Hodder et al., 2009).

Both the established terrestrial planning system and the emerging marine planning system seek to engage the local community and stakeholders at each stage of the planning process - from information gathering, plan and policy making to implementation. Both systems incorporate a Statement of Community Involvement or Statement of Public Participation which set out how local communities and stakeholders will be consulted,

how they can be involved in the formulation, alteration and review of policies and the part they can play in consideration of applications for development. The development of The Marine Policy Statement, for example, was shaped through the involvement of stakeholders through regional and national workshops and consultations on firstly, a discussion paper, followed by a draft policy statement. The latter generated 126 responses across a range of sectors and comments were invited and received on the supporting documents (the Appraisal of Sustainability (including a Strategic Environmental Assessment); Habitats Regulations Assessment, Impact Assessment and Equalities Impact Assessment screening) as well as on the draft policy statement. A summary document (HM Government. March 2011.*UK Marine Policy Statement*) has been published which details the main changes made to the final Marine Policy Statement as a result of public consultation, parliamentary scrutiny, and the policy finalisation process. It also details key comments made that have not been implemented in the final text and reasons for this. One pertinent point of interest was the discussion on how the Marine Policy Statement will prioritise between differing policies and activities and the suggestion that there were implicit priorities in the draft policy statement which inferred that planning should allow or encourage certain activities over others. Comments by respondents to the consultation express a range of views including "too much focus on environmental aspects and not enough focus on socio-economic aspects; the environmental pillar not being given sufficient prominence" (HM Government. November 2010. An Initial Summary of Responses to the UK Marine Policy Statement). There were also requests for more clarity on how conflicts would be managed in the marine planning system.

6.2 Integration of Policy Objectives

Just as land use planning seeks to reconcile competing claims for the use of land, the marine planning system, as expressed in the Marine Policy Statement (2011), seeks to "contribute to the achievement and integration of sectoral/ activity specific policy objectives within a framework of economic, social and environmental considerations". With reference to Marine Plans, which will provide a locally relevant expression of policy, implementation and delivery, a key principle will be to promote compatibility and reduce conflict. Responding to the consultation respondents' comments on implicit policy priorities (HM Government. March 2011.*UK Marine Policy Statement*), the government makes clear that the Marine Policy Statement does not prioritise one activity over another and relative priorities will be most appropriately determined through the marine planning process, taking into account a wide range of factors alongside UK policy objectives, including the specific characteristics of individual Marine Plan areas. On the question of clarity on the management of conflict, the government's response is that Marine Plans should identify areas of constraint and opportunity for a range of activities and that engaging local communities and stakeholders in all stages of the planning process engenders support for plan-led policies, can identify opportunities for compatible uses and minimises potential conflicts. Further, it emphasises the role of evidence in conflict resolution.

7. Conclusion

The above discussion acknowledges that in principle, community renewable energy projects, such as the Poole Tidal Energy Partnership initiative, are an innovative and successful way to supply energy to homes and businesses on a small scale with a range of

associated benefits for local people and ecosystems (Rogers et al., 2012). These type of projects require detailed consideration of financial and technological viability, as well as their potential impacts on the environment. Environmental impacts assume even greater importance when the environment into which the development is introduced is valued for its habitats, species and amenity, particularly, as is the case with significant areas of Poole Harbour, it is subject to statutory designations and legal protection.

Crucial, therefore, to consideration of the Poole Harbour case study, given the government's twin objectives of mitigating climate change through the promotion of renewable energy and sustaining and enhancing biodiversity, is the capability of decision makers to integrate or reconcile these two policy objectives. The question is not whether one policy objective should take precedence over another, but whether spatial planners can work with engineers, ecologists, economists, environmental lawyers, the public and other stakeholders to gather robust evidence to realise renewable energy opportunities with minimal impact to species, habitats or ecosystems.

8. Acknowledgements

We would like to take this opportunity to thank Helena Batlle Argimon, Ann Thornton Roger Herbert for their help and contribution to this work .

LEGAL CHALLENGES FOR GREEN BUILDING RATING SYSTEM

Navid Nishan[1] and Jin-Lee Kim[2]

[1]*Department of Civil Engineering and Construction Engineering Management, California State University, 1250 Bellflower Blvd., Long Beach, CA 90840-5101, USA*

[2] *Green BIM Lab., Department of Civil Engineering and Construction Engineering Management, California State University, 1250 Bellflower Blvd., Long Beach, CA 90840-5101, USA*

ABSTRACT

Sustainable development has gained great interest in the last decade in the U.S.A. and all over the world. The U. S. Green Building Council (USGBC) has prompted sustainable development in built environment. As sustainable building practices are become more popular and acceptable, new legal challenges have accordingly involved. Legal disputes are nothing new to the construction industry, but a green building rating system such as Leadership in Energy and Environmental Design (LEED) has created a new wave of legal challenges. To understand the potential risks involved with this new wave of legal challenges, current and past lawsuits have been examined. The three main areas are identified and classified through a qualitative approach. They include lawsuits against USGBC, lawsuits due to falling short of getting LEED certified or not getting the certificate at all, and legal challenges due to defective design and materials. The findings will inform different parties involved in the green building practices of potential risks and liabilities to avoid future lawsuits.

Keywords: Lawsuits; Leadership in Energy & Environmental Design (LEED); U. S. Green Building Council (USGBC); LEED Certificate; Green Building.

INTRODUCTION

The U. S. Green Building Council (USGBC) encourages owners, architects, engineers, and ultimately the consumers to go "green." USGBC has prompted sustainable development in built environment to encourage stakeholders "to meet the need of present without compromising the future generation's needs" (Our Common Future 1987). USGBC later established Leadership in Energy and Environmental Design, known as LEED, to certify buildings if they meet the minimum performance requirement and then earn the minimum credits for each of four certification levels. The owners choose to pursue LEED for a variety of reasons such as higher rents and assets values and potentially lucrative financial incentives offered by state and local governments (Taylor and Olsen 2012). Owners have started implementing the use of LEED in their planning as a need for projects. Under LEED, a third-party verifies that

[1] esn.navid@gmail.com
[2] jinlee.kim@csulb.edu

a building was designed to improve energy saving, water efficiency and indoor environmental quality, among other environmentally friendly attributes.

While rewards can be gained from the move toward sustainable construction, there are also new risks and unnecessary and costly litigation when the projects fail to perform as promised. A review of the common law of contract damages would be informative as to potential liabilities facing the project participants who are responsible for the success or failure of the project's goals. Moreover sustainability has gain interest in last ten years thus new risks in addition to common risks involved in construction has emerged that could mark a new wave of construction lawsuits. With the growing demand emphasized on sustainability, legal concerns must be addressed. Little attempt has been made to determine the cause of legal disputes on "green" projects. By conducting a thorough review of legal cases on green building rating system, this paper examines the variables from a legal stand point to shed light on legal issues and liability of the various parties involved in a LEED projects to avoid future lawsuits.

Green building is expected to more than double in the next five years (McGraw-Hill Construction's Green Outlook 2011). More industries are getting involved with green building as they build, renovate or expand their facilities to take advantage of improvements in sustainable materials and promises of energy efficiency, cleaner air and tax credits (Hughes 2010). All 50 states in the nation and 91 countries currently have LEED projects underway. According to USGBC an average of $464 million worth of construction register with LEED on every business day. However, major barriers to green buildings in the United States include financial disincentives, insufficient research, and lack of awareness (Kibert 2008). With the new trend of green buildings new problems come. A number of variables influencing legal disputes are identified through a review related articles and court documents on LEED. The next section reviews and groups legal challenges into three main categories. These include lawsuits against USGBC, falling short of getting the desired level of LEED certificate or not getting the LEED at all, and disputes caused by defective sustainable materials and techniques.

LAWSUITS AGAINST USGBC

A well recognized lawsuit against USGBC is the Henry Gifford case. Energy-efficiency consultant Henry Gifford launched a $100 million class action lawsuit against the USGBC, going after them for "Sherman Act Monopolization through fraud, unfair competition, deceptive trade practices, false advertising, wire fraud and unjust enrichment." Lawsuit was later dismissed (Gifford et al. vs. USGBC, Case No. 1:10-CV-07747). Along six allegations two are the most interesting. The Complaint alleges that the LEED rating system is not based on objective scientific criteria or actual measurements; rather it is based on a supportable point system that awards points in a fundamentally weak manner. The Complaint further alleges that USGBC "commissioned a study by the New Buildings Institute (NBI) which: used skewed samples in its data collection; used biased survey takers; compared a set of new LEED buildings to a set of both old and new non-LEED buildings" (Case No. 1:10-CV-07747). The Complaint alleges that these "skewed samples and data are fraudulently misrepresentative and are being used by USGBC to market its system and products through press releases and its website" (Case No. 1:10-CV-07747).

A further study was conducted for the U.S. House of Representatives. An investigation on "the science behind the green building rating system" was launched to determine the credibility of USGBC. The study summarizes the data and identifies key flaws in the NBI's methodology. It indicates that in 2007 USGBC commissioned the New Building Institute (NBI) to gather energy consumption for LEED certified buildings to determine if these building consume less energy. The NBI concluded that LEED certified building on average perform 25-30% better than national average (Turner and Frankel, 2008). With the publication of NBI findings, it immediately came under criticism. A New York mechanical engineer criticized the study on two counts (Case No. 1:10-CV-07747). The first was that the LEED data were volunteered by building owners who were willing to share their data, and therefore it was not representing all LEED certified buildings. Second, NBI's comparison was based on the median energy intensity of LEED buildings with the mean for all commercial buildings. It was stated that the mean energy intensity for the LEED buildings in the NBI study was actually 29% higher than the corresponding mean for all U.S. commercial buildings.

In 2008 the APS Energy Efficiency Study Committee confirmed these allegations by writing, "Whatever their efficiency, these 121 LEED buildings consume more total energy per square foot (either site or primary) than the average for the entire commercial building stock" (Richter et al. 2008). It was stated the "buildings included in the NBI study are probably more efficient than the 80% of the LEED-certified buildings for which NBI was not able to collect energy data" (Scofield 2012). The study summarizes that "analysis of the LEED building energy consumption data gathered by NBI shows that LEED-certified commercial buildings use about the same amount of primary energy as their conventional counterparts. Furthermore, LEED certification has not been useful in reducing building energy consumption and emissions associated with building operation, thus there appears to be no scientific evidence to back USGBC's claims (Scofield 2012).

USGBC'S LEED CERTIFICATION

One of the areas where most lawsuits could potentially arise is not achieving the certification that was anticipated or not getting the certificate at all. This area has the biggest potential for future lawsuit. Regarding this matter several cases had evolved considering the fact that LEED has gain recognition only in the past few years. Looking at reported cases to establish the legal pattern can help to identify some of the issues that have evolved around the failure in achieving LEED certificate or not getting the desired level of certificate. In the research of the current lawsuits some initial pleadings and factual background were uncovered on a state trial court case from two lawsuits that provides some insight. First is Shaw Development vs. Southern Builders. The lawsuit in question is about the construction of a $7.5 million condominium complex in coastal Maryland. From what can be gathered, the initial pleadings included the specifications of a stated goal for the project to achieve a LEED silver certification to be issued by USGBC (Shaw Development vs. Southern Builders, Case No. 19-C-07-011495). The owner was interested in the LEED because of state tax incentives related to new buildings achieving LEED certification. In this case the state of Maryland offers tax credits up to 8% of the total project costs for projects which achieve a LEED certification. These tax credits were not specifically mentioned or claimed in the contract but the LEED certification was clearly stated in the specifications as a sustainability objective. As it turns out the performance of the

project team delayed the receipt of LEED certification which subsequently disqualified the owner from receiving the tax credits, the owner pursued a cause of action against the builder based partially on these lost tax credits.

Another interesting case is Bain vs. Vortex Architect. The project involved the renovation of a three story former farmhouse dated 1883 to achieve a LEED Certificate (Bain vs. Vertex Architect, Case no. 2010L012695). The plaintiff alleges that Vortex Architect breached the architectural contract, stating that "Vertex committed numerous breaches of architectural contract in that it provided architectural services for the project in a manner consistent with locally standards for professional skill and care. Specifically, Vertex failed in its duties as architect for the project on numerous counts including failure to diligently pursue and obtain for the project certification from the USGBC LEED for Home Program" (Case no. 2010L012695). An interesting study by Harvard School of Law indicates that liabilities associated with building green may arise from several legal theories, including failure to deliver a promised level of certification (Bowers and Cohen 2009). In addition to extra cost for building green, parties involved could face potential risks by failure in achieving LEED certificate similar to the two latter cases. To this extend buyer has high expectation for his "sustainable" building, and when the expectations are not met, the owner is held liable.

An owner could also be at risk by failing to receive tax credit for the project. This could substantially affect the outcome of the anticipated project budget as it happed on the Shaw Development project. If the owner is seeking a specific level of certification in order to qualify for tax credit, the owner should seek to make its expectations of achieving the certification and achieving the tax credit clear in the contract document. Parties may also be subject to fraud claims as a result of false or misleading statements made in agreements or other communications regarding the performance or attributes of green buildings. Failure to deliver a promised level of certification, and failure to meet energy efficiency standards can create problems for the owners, design professionals, and contractors involved. Owners could face claims of misrepresenting its building and be accused of false advertising and fraud. As the design professionals' perspective, they could be held liable for not meeting the promised certificate due to defective design. For the contactors, they could be held liable for not delivering features as promised by contract. Moreover the contractors can get in trouble for defective materials and construction techniques.

DEFECTIVE DESIGN AND MATERIALS

Another area that could potentially have high risk for future lawsuits is from defective design and new sustainable materials. An interesting case covering defective design was developed in Chesapeake Bay in Maryland which was the first project that received a LEED platinum from USGBC. The lawsuit in question involved a 32,000-square-foot office building with plaintiff Chesapeake Bay Foundation, Inc, and the defendant being Weyerhaeuser Company (The Chesapeake Foundation INC. vs. Weyerhaeuser Company, Case 8:11-CV-00047-AW). According to suit filed by Foundation, "contractor provided defective, inferior building material" for the Foundation project. Few years after the completion of the project an inspection revealed that deterioration and rotting had occurred on structural members which led to lawsuit against the material's manufacturer. According to the study done by Harvard School of Law construction defects could result from improper installation

that may result from the failure to understand the system (Bowers and Cohen 2009). When an individual is not familiar with a new product or system he or she may install the product improperly, resulting in short life span or failure of the material or failure of the entire system.

Furthermore many manufacturers and suppliers promote their equipment and products as environmentally friendly while they haven't been actually tested and proven. Contractors must be aware of potential unsafe environmentally friendly materials. Also owners and contractors should be aware of the liability of the third party risk involved. The latter lawsuit was an example of potential risks involved with new sustainable materials.

DISCUSSIONS

Examining the reported cases to establish the legal pattern can help to identify some of the issues regarding future litigation surrounding LEED. Unfortunately reported cases on this aspect of green building law are very few to non-existent due to its short existence and it has only gained interest in the last decade. Due to the nature of the research, a qualitative approach has been used to identify where future litigations could potentially arise. Information provided in the literature review is categorized into three categories, Lawsuits against USGBC, shortfall of getting LEED or desired LEED, defective design and materials, and finally other type of claims. Then each category of the three main categorizes has been divided into sub-categories comparing type of litigation, year in which lawsuit was filed, type of claim, total amount of dispute, area of LEED (if applicable), and ruling of the court. The broad types of claim shows the great potential that LEED has for different claims, but some claims have been repeated under each category (ex. Breach of Contract) which indicates the greater potential for future litigations in that specific area.

Building performance is based on design, construction and operation, but LEED is achieved before the building is occupied. The litigation has highlighted the difficulties in ensuring the buildings performance as they are meant to perform and also the problems in developing benchmarks for measurements. To these ends, LEED certification processes are evolving. Under LEED's Minimum Performance Requirements (MPRs), which apply to projects registered under LEED 2009 (except for LEED ND), buildings are now required to commit to periodically submitting energy- and water-use data for at least five years. The relative emphasis in the rating system on reduction of energy use and greenhouse gas emissions associated with buildings systems has also been increased (LEED 2009). USGBC has instituted the Building Performance Partnership, in which participating buildings receive annual performance information, comparing predicted or actual performance at the time of certification with the building's current performance, in order to address the disparity between how buildings are designed to perform and how they actually do perform (USGBC 2012). LEED-NC uses predicted energy cost ($/yr) as the primary energy metric following the lead of ASHRAE Standard 90.1. LEED-EB uses the EPA EnergyStar Buildings program which is based on the measured (not modelled) Energy Use Intensity or EUI (kBTU/sf-yr). EnergyStar normalizes buildings against similar facilities in the US Department of Energy's CBECS database.

Table 1 tabulates the lawsuits related to the three areas. Although the different types of claim have been brought up against USGBC, two are most relevant for the purpose of this study. This lawsuit has a claim under Lanham act that classifies it as a class action lawsuit, has a substantial disputed dollar amount. To avoid future lawsuits similar to the latter case, USGBC has to come up with a proven technique to satisfy all parties involved. Furthermore with the investigation of the House of Representatives more action should be taken from USGBC's part to defend its rating system. Examination of the lawsuits due to failure in achieving the certificate revealed that the dollar amount could vary substantially and no project, big or small, is safe from disputes.

Table 1. Summary of Lawsuits

	Year	Claim	Total dispute amount ($)	LEED	Court ruling
Against USGBC	2000	▪ Violations under the Sherman Anti-Trust Act ▪ Unfair competition under the Lanham Act ▪ Deceptive trade practices under the N. Y. General Business Law ▪ Racketeer Influenced Corrupt Organization Act wire fraud pursuant ▪ False advertising ▪ Unjust enrichment	100 Million	NA	Dismissed on two count, ongoing for 4 counts
Certificate	2007	▪ Negligence ▪ Breach of contract	635,000	Certificate	N/A (Arbitration)
	2010	▪ Breach of architectural contract ▪ Breach of construction contract	50,000	N/A	N/A
Material and Technique	2010	▪ Defective and inferior building material	6 Million	MR	Granted motion, on going

Most of the problems surrounding LEED could be resolved by proper contract documentation. "If the contractor intends to take responsibility for obtaining LEED certification, then it should do so with full knowledge of the contractual risks it is assuming" says Spencer (2010). The contractor may agree to build the project in accordance with LEED principles and help the owner in obtaining credits, but not guarantee LEED certification. There are a couple of industry contract forms that are appropriate in certain circumstances. However industry contracts have generally failed to thoroughly address the unique issues arising in LEED construction projects. Both owners and contractors standard contracts do not address green building risk and liability.

Note that disputed dollar amount could be substantial when it comes to replacing or repairing inferior materials. An interesting finding is that most of the lawsuits had

 ISBN: 978-1-84219-840-7 .

occurred around 2009 and 2010. This might be the peak of sustainable construction or could be because of the recession and shortage of capital. Furthermore by comparison of the litigations, some claims have been repeated in different area of the three main areas, as shown in Figure 1. The graph indicates that most problems arise from breach of contract. A LEED project contract must address responsibility for LEED certification and liability for green materials. The contract must address what damages the parties can or cannot recover related to the LEED process and certification. Contractors should clearly state that energy savings and LEED certification are anticipated, but not guaranteed.

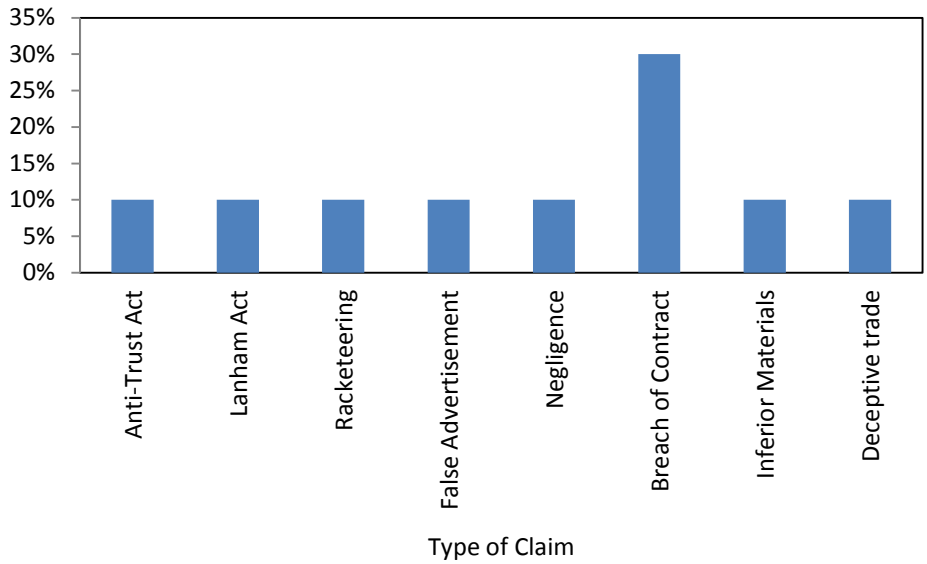

Figure 1: Comparison of total number of claims

CONCLUSIONS

It is clear that sustainable construction isn't going away anytime soon. The new wave of lawsuits in the construction industry must be minimized by thorough investigation into vulnerable areas of LEED. This paper has examined the areas in which past lawsuits had occurred in light of foreseen the near future of legal issues surrounding LEED. A number of variables influencing legal disputes were identified followed by a thorough review of the variables based on related articles and court documents. Study of previous literatures suggests that legal challenges are grouped under three main categories. These include lawsuits against USGBC, falling short of getting the desired level of LEED certificate of not getting the LEED at all, and disputes caused by defective sustainable materials and techniques. Once categorized, it was noticeable that in each area there is pattern with regards to year, type and dollar amount of each category. A further comparison of all three main categories revealed that the breach of contact plays a significant role in disputes. It was found that the size and scale of the project may not affect the risk of having a lawsuit on hand. The major factor for the dollar amount of the claim is the potential damage to the damaged party. The weaker attribute in comparison was court rulings. To address the latter issue future studies have to be conducted. It is unquestionable that sustainable construction will be an increasingly important topic in the years to come, hence as a new wave of construction lawsuits arise, trained lawyers in this area of construction are needed to tackle these waves.

Abstract:
Main trends towards year 2100 predict a worsening climate, with prospects of grave impacts to the built environment. If appropriate measures are not effectuated, the built environment will struggle to endure the impacts of aggravating climate strain. Vulnerability and adaptive capacity to climate change in the built environment is depending on the legal framework and its implementation in the construction industry. Earlier, the Norwegian planning and building legislation was indistinct in climate related matters. During the latest decade the legal focus on climate has however undergone considerable changes. The paper displays the latest, climate related amendments of the Norwegian planning and building legislation. Further, it discusses possible effects of the amendments and statutory interpretation performed by professional building process participants. Finally, a reflection of whether and how the amendments will lead to the obtaining of successful adaptation to climate aggravations in the built environment is presented. The methodological approach is based on a theoretical overview extracted from an annotated bibliography in the ongoing research project BIVUAC (Building and Infrastructure – Vulnerability and Adaptive Capacity to Climate Change), and results from a qualitative case study in the ongoing priority program Climate 2050 at SINTEF Building and Infrastructure (SINTEF B&I).

Keywords:
Building process, built environment, climate adaptation, climate change, legal amendments.

1 Introduction

Main trends towards year 2100 predict a worsening climate, with prospects of grave impact to the built environment. If appropriate measures are not effectuated, the built environment will struggle to endure the impacts of aggravating climate strain. Vulnerability and adaptive capacity to climate change in the built environment is depending on the legal framework and its implementation in the construction industry. Earlier, the Norwegian planning and building legislation was indistinct in climate related matters. During the latest decade the legal focus on climate has however undergone considerable changes.

The importance of adaptation to varying local climatic challenges has drawn attention in several Norwegian research projects (Lisø and Kvande, 2007; Eriksen et al., 2007). Local adaptation, both to present climate variations and to climate change, is dependent on institutional, technological and financial resources critical to the capacity to undertake actions (Næss et al., 2005; Smith et al., 2003; Yohe and Tol, 2002). How actual institutional relations and features can promote or constrain adaptation actions is however less explored (Eriksen et al., 2007; Eakin and Lemos, 2006). The implementation of legislative requirements, policies and local authority decisions through local policy instruments and other tools have been distinguished as important in promoting climate change issues (Tompkins and Adger, 2005). Sorrell (2003) argues however that the institutional organization of a sector may seem barrier-building and can impair the effectiveness of legislation in advancing climate-related issues, demonstrated through building sector examples from England. This is parallel to findings in e.g. case-studies of the Norwegian building sector and the Mexican water regulation sector (Eriksen et al., 2007; Eakin et al., 2011).

2 Objectives and methodological approach

The paper displays the latest, climate related amendments of the Norwegian planning and building legislation. Possible effects of the amendments are enlightened. Further, discussions on the interpretation of statutory requirements by local authorities and professional participants of the building process and their implementation in practice are displayed.

2.1 Objectives

Main objectives in the discussion are:

- How is climate adaptation of the built environment ensured through the Norwegian planning and building legislation?
- How are the legal provisions implemented and effectuated by the public and professional participants of the building process?
- Does the implementation of legal provisions seem to adequately support necessary actions for adapting both existing and new built environment to climate change?

2.2 Method

The methodological approach is based on a theoretical overview extracted from an annotated bibliography (not yet published) in the ongoing research project BIVUAC (Building and Infrastructure – Vulnerability and Adaptive Capacity to Climate Change), and results from a qualitative case study in the ongoing priority program Climate 2050 at SINTEF Building and Infrastructure (SINTEF B&I). The objectives are enlightened through a discussion of the empirical findings towards the theoretical background. Possible actions are presented with the conclusions. BIVUAC is a multidisciplinary joint research project of SINTEF B&I, and Vestlandsforskning, funded by the Research Council of Norway. The Climate 2050 project is an in-house Climate Change Priority Programme at SINTEF B&I.

 ISBN: 978-1-84219-840-7 .

3 Theoretical overview - Background

Developing countries have so far been subject to the main attention with respect to climate adaptation and anticipated problems. Adaptation in developed countries with higher financial, technological and institutional capacity has been assumed to be largely unproblematic. Due to exposure to climate change and lacking adaptive capacity, developed countries may too have vulnerability issues (Morrow, 1999; O'Brien et al., 2004a). As other western societies, Norway may be less prepared for a changing climate than what has been assumed (O'Brien et al., 2006; IPCC, 2007).

3.1 Present and future climate in Norway

Norwegian climate is extremely varied. Large spatial and seasonal differences are due to vast geographical and topographical variations. A long coastline and rugged and steep topography makes the built environment particularly vulnerable to a harsh, cold and wet climate. The western and northern coast experience frequent and extreme weather events such as coastal storms, heavy precipitation, avalanches and landslides. The same areas endure the highest mean temperatures, the heaviest loads of precipitation and the strongest storms of the country (Lisø, 2006).

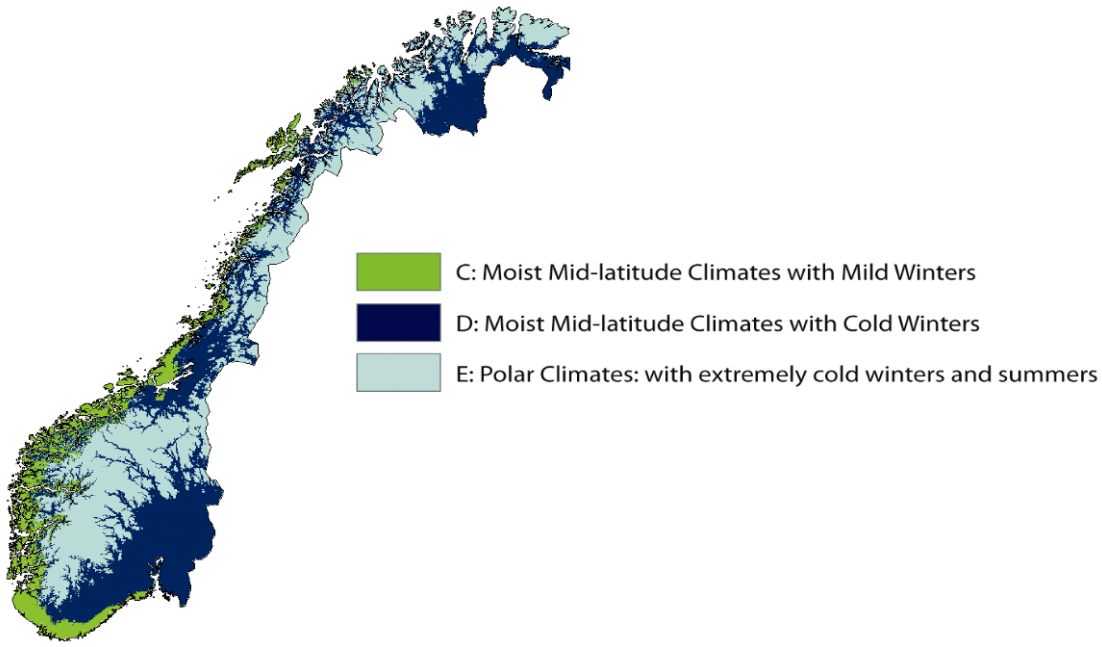

FIGURE 1. The climate of Norway based on the Köppen Climate Classification System (developed by W. P. Köppen around 1900). The map is prepared by the Norwegian Meteorological Institute, using weather data (annual and monthly averages of temperature and precipitation) from the reference 30-year period 1961–1990 (Lisø 2006).

Climate change impact in Norway will induce increased amounts of mean annual precipitation (www.met.no). Precipitation during summer, autumn and winter will increase the most. The strain will likely be most aggravated in areas that already experience the toughest conditions. Extreme weather events will occur more frequently.

Increased amounts of precipitation will lead to higher water pressure on the ground, resulting in erosion, landslides, and more frequent flood incidents. The amounts of snow during the winter season will likely diminish in large parts of the country, and more often be converted into wet precipitation.

3.2 Climate challenges and the built environment

Precipitation, wind, temperature and combinations of these cause costly damage to the built environment. Indirect climate strain, such as ground water level and -pressure, and flooding, may as well lead to severe moisture related building defects in both existing buildings and new buildings during the construction process.

Local and regional climatic diversity has historically been reflected in considerable local and regional differences in building styles (Eakin et al., 2011; Eriksen et al., 2009). Continuous development of material, production methods and industrialization, solutions, marked demands, knowledge, design, legislation, standardization, etc. have however lead to an increased uniformity, leading to the neglecting of local and regional differences in climate challenges (Lisø and Kvande, 2007; Øyen et al., 2012). The building industry is struggling with a relatively high number of moisture related building defects; often recurring faults, and a high number of climate strain induced defects. The SINTEF Building and Infrastructure Building Defects Archives display that as much as 60 % of process induced building defects origin in the early stages of the building process, prior to construction initialisation[1].

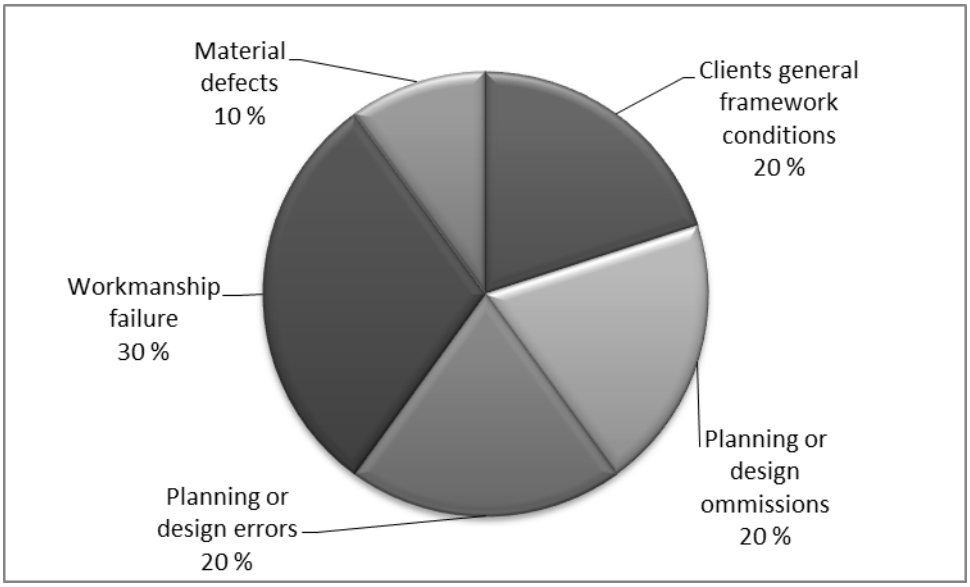

FIGURE 2. Process induced building defects distributed by source of defects. The figure displays that up to 60 % of process induced building defects origin in the early stages of the building process. The figures are drawn from the SINTEF Building and Infrastructure *Building Defects Archives* (Lisø et al., 2006).

Lacking implementation of climate aspects in tools and policy instruments may be some of several causal relations. So may issues related to local and regional diversity in

[1] Process induced building defects origin during the building process but are discovered subsequent to the client's acquisition of the building

climate challenges (Lisø and Kvande, 2007), as well as changes in public institutional organization (Eriksen et al., 2007 and 2009).

3.3 Planning and building legislation: Development and amendments

The early versions of the Norwegian building legislation did not embrace planning. Since 1845 the Norwegian building legislation has been subject to numerous revisions, also serving as a historically important tool for the social government in forming the Norwegian built environment. In 1965, Norwegian municipalities experienced a large transformation through the conversion of the planning and building legislation into a performance-based and more general level framework. This was partly caused by an increased frequency in revisions due to a heavily expanding focus on building material (Bratberg, 1995).

A simplified and decentralized decision process was implemented in 1985, also embracing land use planning. The new Norwegian Planning and Building Act of 1985[2] has hitherto undergone two major amendments, (1995/-97 and 2008/-10). Severe downscaling of local authorities' technical activities in the nineties, weakened the local planning and building authorities´ ability of guaranteeing the implementation of legal provisions, and led to an unclear distribution of responsibilities (Nørve, 2005). An extreme storm event on New Year´s Day in 1992 uncovered the strong need for increased quality demands, becoming a major driver behind the 1995/-97 legislative amendment. Refocusing on liability, control, appropriate skills and qualifications in building projects, an alteration of foci and a radical change of application processes for Norwegian municipalities was entailed (Øyen, et al., 2007). Clear distribution of responsibilities and roles, implementation of internal and independent control, and reintroduction of municipal supervision in construction projects were important efforts.

Previously, knowledge of local conditions was incorporated in building projects both by professional participants and through executive work in municipal administrations. By removing the means of ensuring incorporation of local concerns early in the building process, an important level of quality assurance incorporating local climate conditions disappeared. As a remedy, start-up meetings for planning and preliminary conferences for building applications were introduced (Berg, 2005; Nørve, 2005; Øyen et al., 2005). The aim was to inform stakeholders of the municipal intentions in local land use planning, implementation of statutory provisions, and specific local conditions.

The implementation of a centralized liability certification system transferred a majority of responsibilities from the local authorities on to professionals in the building industry (Berg, 2005; Nørve, 2005; Øyen et al., 2005). Thorough control in the building process should fulfil the aim for both a general improvement, and adequate skills.

Public supervision was formalized, leading to changes in municipal tasks relating to the approval processes (Eakin et al, 2011). Although the aim was to reduce the number of defects in planning and constructing buildings (Nørve, 2005; Øyen et al., 2005), moisture and climate adaption were not subjected prior to, nor in, the amendments effectuated in 1997.

[2] The Norwegian Planning and Building Act, LOV-2008-06-27-71, latest amendments of 2012.01.01. The Ministry of Environment and the Ministry of Local Government and Regional Development

3.4 Planning and building legislation: Current provisions

The main purpose of the recent legislative changes has been to simplify an inappropriate, overly complex and unsystematic legislation. A holistic review should provide easier and faster processes as basis for i.a. time use, defects and cost reductions. The latest amendments require that all Norwegian municipalities develop risk and vulnerability analysis. The assessing of local climate conditions and mapping of potential risks relevant to the building stock is an important step to obtain a climate adapted built environment. The strengthening of the climate focus in the latest amendment was primarily driven by research (Lisø and Kvande, 2007) and legislative preparatory work[3,4] emphasizing that climate related issues were lacking in previous versions of the legislation.

The latest amendments of 2008 are aiming at rationalizing the planning and building legislation. A number of newly introduced climate related topics are now included both in the Planning and Building Act, technical building codes (TEK 10[5]), and procedural regulations (SAK 10[6]). Mandatory risk and vulnerability analyses (ROS) conducted by local authorities are introduced, to better ensure climate related aspects in the planning process**Error! Bookmark not defined.**. The building codes state that new buildings should adequately protect against damage or natural stresses through proper building positioning, design and construction. In addition, building site and adjacent terrain should not be exposed to consequential damage or significant risk.

Needed building robustness level is ensured through internal or independent technical control. In each project, local authorities with knowledge of local climate should determine the nature of control and which areas should be targeted. Preliminary meetings in planning projects, preliminary conferences related to the building application approval process, and other policy instruments, are some of different possible arenas for dissemination of such information.

4 Empirical case study findings

As the case study of the BIVUAC project is not yet concluded, empirical findings of the ongoing PhD of one of the authors, and the in-house SINTEF B&I project Climate 2050, are employed to enlighten the different aspects addressed in the paper. The findings of the PhD case study focus on several corresponding and adjacent subjects, highly relevant to the BIVUAC research areas. The findings of the PhD study will therefore provide valuable information relative to elucidate the selected issues in the paper, and is also of great value when executing the BIVUAC case studies.

4.1 Municipalities: Implementation and incorporation of provisions

As opposed to the intentions, few municipalities have so far implemented the climate related issues in of the latest planning and building legislative amendments. The topics are neither reflected in municipal planning, building application procedures nor other policy instruments. Development of mandatory Risk and Vulnerability Analyses (ROS) have to date been initiated only by a small number of municipalities. ROS analyses are of an interdisciplinary character, displaying a cross-section of different areas of the society and its exposure to risk. In this context, ROS analyses should be a foundation for the development of different policy instruments focusing on climate strain and possible climate change impacts for the nation at a general level and for the individual municipality in specific.

Main findings related to municipal planning and processing of building applications are as follows:

- Lacking focus on climate related issues in general and climate change in particular in planning and building sections of Norwegian municipalities. This is most apparent in municipal management; there is a clearer climate related focus at executive levels;

- Lacking development of ROS analyses as basis for other policy instruments;

- Lacking implementation of climate related risk issues and directions in municipal plans, provisions, guidelines, information forums and other policy instruments;

- Municipal knowledge of local climate challenges highly present, but primarily informal, individual, person depending, and non-formalized (oral, not written); and

- Climate adaptation and climate vulnerability concerning building process and property-related issues are by several municipalities seen as strictly professional participants' responsibilities.

The findings indicate that municipalities are falling behind, struggling to update systems and management of law at the same rate as the legislative development. Due to lacking attention to climate aggravations this may implicate ripple effects far beyond the planning and building sector, and could have negative impacts on the built environment in specific, and the social security in general.

4.2 Professional participants of the building process: Climate adaptation in practice

Despite the fact that climate adaptation is not subject to a comprehensive management in the municipal sector, it lately seems to having received greater attention in the private sector among the professional participants of the building process. As the level of building defects still seem to be at a proportionally equal rate as in the previous years, the private sector is however evidently struggling with a persistent problem of building defects' generation.

 ISBN: 978-1-84219-840-7 .

Figure 1. Private residence project in construction with weather protection to avoid climate or moisture related building defects during the building process. (Photo: Augustinius J., 2011)

Main findings related to professional participants of the building process are as follows:

- Several new, mandatory tasks of control, surveillance, responsibilities/liabilities, verification processes, forms, etc. are introduced the latest decade. Many have come in addition, instead of as a replacement, for former tasks and working methods. A feeling that the bureaucracy has caught up with the crafts enterprises is widespread among players in the building process;

- The number of building defects is too high, and several are recurring defects. It seems that the players of the building process are not able to learn from own mistakes;

- As moisture and climate strain presently lead to a high number of defects, it is reasonable to question whether the construction industry is capable of adapting to a changing climate;

- Climate change can, for some professional participants (designers and contractors), in itself be a major driver. It may lead to increased focus, innovation and consideration of climate related strain in technical development. In order to avoid cost increase, building defects, claims, insurance rate increase, and a bad reputation, the larger building contractors and organizations tend to have a more distinct focus on climate related issues than in the past. This does not necessarily apply for the smaller companies. However, the harshness level of local climate challenges seems to have an impact on the attention paid to climate adaptation measures; and

- Although the focus on climate change and climate adaptation increasingly appears to be maintained among the players in the building process, new tools to assist professional participants are not correspondingly developed. Considerations to climate

and climate change are to some extent incorporated into existing tools and procedures for design, construction and control. However, it still seems that the players are (as in the municipal sector) relying on informal (personal) climate expertise and that incorporation of local climate challenges largely is based on non-explicit knowledge.

The two latest amendments of the planning and building legislation have been focusing on both simplification and efficiency improvements of the building process. This process has led to a large formal change for the operation of private enterprises operating in the construction industry. Many small businesses have teamed up with other, often larger firms. These operational changes have cleaned up the construction process, but have also led to larger bureaucratic responsibilities for the enterprises. It may seem that the professional participants in the building process to a certain degree have added new statutory responsibilities besides the existing rather than to incorporate and develop new customized routines.

5 Discussion and conclusions

5.1 Discussion

The introductory mapping of the Norwegian planning and building legislation gives a general review of how climate adaptation of the built environment is ensured through the Norwegian planning and building legislation. The legislation deals with organization of the building process, and sets specific functional requirements to the completed buildings. Further, formal requirements to tasks and responsibilities' apportionment, planning and building application processes, control at all stages of the building process, and municipal supervision should ensure a surveyable and orderly building process.

The performance based regulations set requirements for building performance at a general level, where issues including climate change considerations and moisture safety shall be ensured. Climate change aspects are therefore seemingly well incorporated in the current planning and building legislation. Our findings, also supported by previous research, do however demonstrate that climate change is not sufficiently safeguarded in the construction process. The implementation and effectuation of legal provisions by the public and professional participants of the building process must therefore provide an answer to why. The current legislation applies only to a certain extent, existing building stock. The maintenance backlog of existing buildings is large, making the existing building stock even more vulnerable to climate strain and climate change. This subject has however not been approached in this paper.

According to Næss et al. (2005), technical and legal framework will not necessarily ensure the implementation of adjustments of administration and practice needed. Further, O'Brien et al. (2004 B) maintain that fundamental institutional and economic conditions are as important as mere technical adjustments as adaptational strategies in reducing negative impacts and taking advantages of potential positive effects of climate change. O'Brien et al.(2004 B) see institutional interaction, research and development, public administration, and policy and legal frameworks as equally important.

The findings indicate a mismatch between the local authorities' safeguarding of climate adaptation, or lack of such, and the mandatory, bureaucratic tasks players in the

construction industry must follow to operate in the building process without losing their accept responsibility.

Beyond being registered as a responsible player in a specific construction project, contractors are not involved in the municipal planning and building process. This is not a problem as long as the client and/or the designer exercise good practice in providing continuous information from local authorities to all involved stakeholders in the building process. If the local planning and building authorities, as seen in a large number of municipalities, do not perform vital mandatory tasks but leave this to the professionals, both the obtaining and the transfer of information concerning local climate conditions is up to the client and the designer. If the local authorities however do perform risk and vulnerability analyses as intended, the dissemination of vital information of local climate conditions must be safeguarded to all players of a building project by the municipality. This may not always be the case today, especially when considering the low level of risk and vulnerability analyses actually performed. This pinpoints problems both in implementing climate related issues in local authorities' planning and handling of building applications, and in their transfer of information to the building process stakeholders.

5.2 Conclusions

That several of the Norwegian 340 municipalities have not performed or developed risk and vulnerability analyses, as decreed by law, nor communicate climate change and adaptation through their diversity of policy instruments as important issues to regard during the different stages of the building process, is a serious problem. The balance in apportionment of mandatory responsibilities and tasks between local authorities and professional participants of the building process is subtle, yet important in order to achieve a sustainable and robust built environment. The public authorities are also pronounced as role models. When they do not fulfill their obligations, possibilities of others following their example will increase. The difference between large and small enterprises in the construction industry is admittedly large, as is their conduct and attention to climate change and adaptation. However, it seems that at least the larger enterprises have commenced the incorporation of climate adaptation in design, construction and control.

Despite the fact that the amendments should simplify the legislation, and yield a more transparent and predictable building process, as of yet this is not an obvious outcome. It seems that several of the forms are filled out, and operations are performed, just because it is required. In many cases these procedures are not yet incorporated as a natural part of the "new" building process.

The number of building defects due to moisture and climate strain is also still unfortunately too high, even though this is not a direct empirical finding in our study. As many of the municipalities and professionals often do not formalize personal knowledge (so called silent or non-explicit knowledge), this may be one of the answers as to the high number of recurring building defects. Simultaneously, this may be an important future source of knowledge both of local climate challenges, locally adaptive building styles and choice of adequate detail solutions. Increased formalized documentation of experience based competence will enable a broader learning platform.

This will enable learning from each other's mistakes and experiences in a far larger scale than is the case today.

Whether and how the amendments will lead to the obtaining of successful adaptation of the built environment to climate aggravations, is an important question. At present it does not seem that the amendments of the planning and building legislation has had the wanted effect. The findings do however not substantiate that the design of the legislation is not satisfactory, but rather that the local planning and building authorities have not followed the legal changes and new regulatory requirements through the development of municipal plans and policy instruments. This may have several causal connections; staff shortage, lack of funding, still too complex processes, too heavy workloads etc. At this, it is rather a question of enforcing the legislation through incentives or penalties for not following the statutory responsibilities imposed on Norwegian municipalities (and counties that do not follow the local authorities). This is presently the case for professionals, if gravely violating the legal requirements, through withdrawal of their right to accept responsibility.

In conclusion, it seems that the legislation serves its purpose of enhancing the focus on climate change and need for adaptation adequately, but that the implementation of the legal requirements through the local authorities is not correspondingly sufficient. Thus the implementation of legal provisions does not seem to adequately support necessary actions for adapting the built environment to climate change.

Our findings display a need for a thorough evaluation of the effects of the revised legislation implementation and effects on professional practice are needed in order to pinpoint the exact areas of further improvement. Causal connections as of why the local planning and building authorities are not capable of keeping up with the legislative development speed should also be subjected in further research.

Abstract:
The Energy Performance of Buildings Directive (EPBD) 2002/91/EC introduced various obligatory requirements intended to achieve the reduction of use of energy resources in buildings. This directive had to be transposed into national legislation by the EU member states. Concurrently the European Committee for Standardisation (CEN) developed a number of technical standards to assist member states to define the methodology for the calculation of the energy performance of buildings. Whilst the system and procedures for energy certification in Northern European States are now mature, a number of Southern Mediterranean states have only recently introduced the procedures for the issuance of energy certificates for buildings. This paper presents a comparative review of the relationship between the European directive and the standards, and the different country legislation and methodologies that have been implemented in Malta, Italy, Spain and Cyprus.

Keywords:
Energy certificates, EPBD, Mediterranean states, residential buildings, standards and legislation.

1. Introduction

The European Energy Performance of Buildings Directive (EPBD) 2002/91/EC introduced various obligatory requirements intended to achieve the reduction of the use of energy resources in buildings and, consequently, the reduction of the environmental impact of energy use in buildings. Article 7 of the directive formally specified the current European requirement for the energy certification of buildings. In order to implement this requirement, a general framework for establishing a methodology of calculation of the total energy performance of buildings became necessary. A total of

30 European (EN) standards and 24 international (EN ISO) standards were drafted in order to define the necessary procedures to be introduced following the ratification of the EPBD. In 2010, a recast of the Energy Performance of Buildings Directive 2010/31/EC was adopted by the European Parliament and the Council of the European Union in order to strengthen the energy performance requirements and to clarify and streamline some of the provisions from the 2002 Directive.

Over the years a number of EU member states found difficulty in the transposition of the EPBD and some are still struggling with practical implementation issues (Dascalaki et al, 2012).

Apart from the difficulties in the transposition and implementation of the EPBD, compliance and control are essential for the successful operation of the directive. Three factors have been identified for the effectiveness of a successful compliance and control strategy (Poel and van den Brink, 2009), namely:

- The existing legal and regulatory system in the country. In states where the legal responsibility is delegated to regions, the federal legal structure should facilitate the implementation for the regions. In these states a centralised implementation is unlikely and diversity in compliance and control instruments can occur.

- Cultural aspects related to the interaction between the citizen and the state. In some countries strict enforcement is the common approach, while in other countries control schemes may be based on self-regulation.

- The political and economic policy of the government. The current national objectives might not necessarily coincide with the objectives of the EPBD.

This research examines the implementation of the directive in a number of Mediterranean states, namely Italy, Malta, Cyprus, and Spain. Although a general overview is taken, the focus of this work is on the state of implementation of the section of the directive relating to the energy certification of residential property, as this is the main area of the authors' research.

2. Italy

In Italy both the national and the regional governments are jointly responsible for technical standards and building regulations relating to energy. As a consequence, there are two levels of standards and regulations, a national level that establishes the national minimum energy performance requirements and a regional or local level that could be more onerous.

A different consequence of the regional independence is that a number of regions have not yet implemented a certification scheme (Antinucci, 2011). The majority of these regions are in the South of Italy.

 ISBN: 978-1-84219-840-7 .

Legislation

The Energy Performance of Buildings Directive (EPBD) 2002/91/EC was ratified in Italy by two decrees, namely Legislative Decree no. 192 of the 19th August 2005, subsequently amended by Legislative Decree no. 311 of the 29th December 2006, which established the general framework for the implementation of the Directive and updated the performance requirements for new buildings. These were supplemented by Legislative Decree no. 115 of the 30th May 2008 that defines the qualifications of the professionals involved, by Presidential Decree no. 59 of the 2nd April 2009 that defines the technical standards to be used for the calculations, and by a Ministerial Decree issued by the Ministry for Economic Development on the 26th June 2009 establishing the national guidelines for the energy certification of buildings. The Ministerial Decree defines the calculation methodology for the assessment of the energy performance of buildings in accordance with the national standard UNI TS 11300.

Technical Standard

Several CEN documents were adopted as Italian standards. The UNI TS 11300 series of technical specifications was developed to define the national calculation method for determining energy performance of buildings and is divided into four parts:

- Determination of the thermal energy demand of the building in summer and winter;
- Determination of the primary energy requirements for winter heating and domestic hot water production;
- Determination of primary energy requirements for summer air conditioning;
- Use of renewable energies and alternative methods of generation for space heating and domestic hot water preparation.

The standard also defines three different methods for the calculation of the primary energy for heating, cooling and domestic hot water. The first is a detailed method applicable for all building typologies. The second is a simplified method for the calculation of the energy performance of existing residential buildings with a net area below 3000 m^2. The third method is applicable to residential buildings with a net area below 1000 m^2, using a simplified method.

The standard proposes three different types of energy assessment:

- Design assessment: the calculation is performed on the basis of design data whilst assuming continuous operation of the building and the technical systems.
- Standard assessment: the calculation is performed on the basis of the as-built data for the building and the plant, whilst assuming continuous operation of the building and the technical systems.
- Assessment in actual conditions: the calculation is performed on the basis of the as-built data for the building and the plant, whilst assuming the actual operating schedules for the building occupancy and technical systems.

A simplified reference calculation tool, DOCET, was developed by ENEA (the Italian National Agency for New Technologies, Energy and the Sustainable Economic Development) together with ITC-CNR (Construction Technologies Institute – The Italian National Research Council) as a reference energy performance calculation

method for residential buildings. This tool was further developed in 2010 by ITC-CNR into DOCET^{PRO}. The software is based on the simplified monthly method (Belussi et al, 2010).

Implementation

Due to the regional autonomy mentioned earlier, there were a total of ten defined regional systems in 2010, with over two million energy performance certificates (EPCs) issued.

Compliance

Italy is one of the two Mediterranean states currently undergoing infringement procedures in connection with the EPBD. In 2010, the European Commission formally requested Italy to comply with the directive. The Commission felt that Italian legislation on energy performance certificates for buildings did not comply with the requirements of the Directive and that Italy had not adopted any measures regarding the requirement to carry out regular inspections of air-conditioning systems in order to evaluate their performance (IP/10/1561). Again in 2011 the Commission informed Italy about its lack of compliance with the relevant rules (IP/11/1100). Although the Italian authorities had taken additional measures, the Commission considered that the Italian legislation still did not fully comply with the EU requirements. Specifically the Commission felt that the Italian law did not ensure that every new owner or tenant of a building receives information on the future energy costs or recommendations on how to improve the energy performance of the building in a cost-effective manner. Furthermore, Italy had still not put in place the necessary measures to ensure regular inspections of air-conditioning systems. These inspections should ensure the optimal performance of the systems and should include advice on possible improvements and on alternative solutions. Finally in 2012, The Commission decided to refer Italy to the EU's Court of Justice for failure to fully comply with Directive 2002/91/EC on the energy performance of buildings (IP/12/1411). The Commission feels that Italian legislation is not in line with the provisions on energy performance certificate, and that Italian authorities have not yet communicated any implementing measures regarding inspections of air-conditioning systems. An infringement procedure had previously been opened in 2006 against Italy due to the incomplete and incorrect transposition of the Directive. The Commission felt that despite several letters of formal notice and reasoned opinions to the Italian Authorities, the Italian legislation is still not in compliance with the Directive.

3. Cyprus

The implementation of the EPBD in Cyprus is the responsibility of the Energy Service Division of the Ministry of Commerce, Industry and Tourism. The Energy Service division has developed and implemented a certification scheme with a single methodology for both residential and non-residential buildings. Certification of both categories of building became mandatory in 2010.

Legislation

In Cyprus, the transposition of the EPBD into national law was achieved through the Law for the Regulation of the Energy Performance of Buildings of 2006-N.142 (1)/ 2006 and its Amending Law N.30 (1)/2009. Secondary legislation has been issued for the regulation of various aspects of the directive, such as the national methodology, the minimum requirements for energy performance, the certification procedure for

 ISBN: 978-1-84219-840-7 .

buildings, the inspection procedure for boilers and air conditioning systems, and the qualifications of experts and inspectors.

Technical Standard

The core of the methodology for the calculation of the annual energy use for space heating and cooling is the monthly quasi-steady state method defined by the EN ISO 13790 standard. In addition, the methodology makes use of a number of other standards developed for the EPBD and outlined in the CEN Technical Report 15615:2008 Umbrella Documents. The actual calculation tool was based on iSBEM (interface for the Simplified Building Energy Model) developed by the Building Research Establishment (BRE) for the Department of Communities and Local Government in the U.K. This methodology was developed further by the BRE in conjunction with the Energy Service Division of the Ministry of Commerce, Industry and Tourism in Cyprus so as to meet the specific requirements of the Cypriot building stock and climate. The software tool provided by the Energy Service Division for the certification is SBEM-CY (Simplified Building Model Cyprus).

The Cypriot calculation methodology relies on the use of a notional building, i.e. a building which has the same geometry, location, building function, and size as the actual building, but with parameters such as insulation values, heating system efficiency, internal gains, etc., substituted by reference values. The methodology performs two calculations, one on the actual building and one on the notional building, the latter providing a benchmark. The ratio of the primary energy of the actual building to that of the notional building is used to provide the classification of the actual building.

Implementation

The requirement for an EPC is linked to the issue of a building permit for construction works through Regulation 429/2006 which makes it mandatory to submit an EPC to the building authority prior to the issue of a building permit. This ensures that an EPC is issued for all new buildings. However it is not obligatory to convert the original EPC, which is a design certificate, to an as-built EPC with actual data on completion of the building. This was thought to involve higher costs for the consumer and be a more onerous administrative burden for the building authorities (Panayiotou et al, 2010).

One of the minimum requirements for the energy performance of new buildings is their classification as a class B or better, implying that the new building should achieve a better energy performance than the notional building, as class B is equivalent to between 0.5 and 1 times the energy performance of the notional building.

Approximately 2000 certificates were issued during 2010 which was the first year of operation of the scheme. A quality assurance scheme operated by the ESD checked 16% of all certificates issued which were flagged as requiring additional verification and just over 30% of these were cancelled (Xichilos and Hadjinicolaou, 2011).

 ISBN: 978-1-84219-840-7 .

4. Malta

The implementation of the EPBD in Malta is the responsibility of the Building Regulations Office of the Ministry for Resources and Rural Affairs, although the legal authority is vested in the Malta Resources Authority. The putting into practice of the certification methodology commenced during 2011 and only certificates for residential property have been issued so far.

Legislation

Malta implemented the EPBD by means of Legal Notice 261 of 2008 (Malta Resources Authority Act – Chapter 423) Energy Performance of Buildings Regulations, 2008. This legislation superseded Legal Notice 238 of 2006 but keeps the former technical guidelines on the 'Minimum Requirement on the Energy Performance of Buildings'. The new legislation transposed all of the Directive's clauses to national law.

Technical Standard

The EPRDM (Energy Performance Rating of Dwellings in Malta) methodology for the energy certification of residential property was developed locally by the Buildings Regulation Office in accordance with EN 13790, using the steady state monthly method. The methodology for non-residential property was based on iSBEM, developed by the BRE for the Department of Communities and Local Government in the U.K. This methodology was developed further by the BRE, in conjunction with the Ministry for Resources and Rural Affairs in Malta, so as to meet the specific requirements of the Malta building stock and climate. The software tool provided for the certification of non-residential property is SBEM-MT (Simplified Building Model Malta).

Whilst both methodologies provide an energy rating in terms of kg CO_2 per m^2 of floor area, the energy rating for residential property is an absolute value in numerical terms whereas the rating for non-residential property is a scale from A to G, based on the comparison between the rated property and a notional property with the same geometry, location, building function, and size, but with parameters such as insulation values, heating system efficiency, internal gains, etc., substituted by reference values.

Implementation

Although the EPC is required for the issue of a building permit for construction works, the building authority is not obliged to refuse the issue of a permit if the certificate is not presented. The main drive for the issue of certificates appears to be related to property transfers. The methodology for the certification of non-residential buildings is currently being rolled out and training of experts in the certification methodology commenced in the first half of 2012. Approximately 250 certificates were issued for residential property in 2011.

Compliance and Certification

In the Maltese islands the project architect has the legal obligation to verify that the building design meets or exceeds the national minimum energy performance requirements when submitting an application for new construction to the Malta Environment and Planning Authority (MEPA) and this has been a legal obligation since January 2007. At the same time the owner is obliged to commission an energy performance assessor to produce a design rating EPC for the building. In the case of

large developments MEPA refers the project designs for specific consultation on energy performance and use to the Malta Resources Authority (MRA) among other entities. The MRA has to refer the designs to the Building Regulation Office (BRO) which assesses the project designer's calculations and reports to see whether the buildings meet the minimum requirements. If the latter are not met the BRO sends its feedback to the project architect requesting appropriate revisions.

When MEPA issues the planning permission, the project architect follows on by supervising the project throughout its construction and finishing phases. When the finishing has reached its final stages the owner should commission an energy performance assessor to produce the mandatory EPCs based on the asset rating energy performance. The latter is obtained from calculations that depend on the useful floor area, building function, type of building fabric and external finishes that would at least meet the minimum requirements.

The EPCs are quality checked for accuracy of content and recommendations by the BRO as the central EPC database is held at the same office. The BRO also scrutinises all MEPA applications and requests design rating EPCs from the building owners when applications for building permits are validated and accepted by MEPA.

5. Spain

The implementation of the EPBD is the responsibility of the Ministry of Industry, Tourism and Commerce and of the Ministry of Housing. The Spanish regions are independently responsible for the registration, inspection and control of EPCs. The EPC is valid for a maximum period of ten years. This may be shortened by the individual regions, although none have done so as yet.

Legislation

The transposition of the EPBD in Spain has been achieved through the following Royal Decrees:

- Royal Decree 314/2006 of the 17th March, approving the Technical Building Code (CTE)
- Royal Decree 47/2007 of the 19th January, approving the basic procedure for the energy certification of new buildings
- Royal Decree 1027/2007 of the 20th July, approving the Thermal Building Regulations (RITE)

Legislation for the energy certification of existing buildings is required to complete the transposition of the EPBD but this has not yet been enacted. A draft royal decree was published in 2012 defining the basic procedure for the energy certification of existing buildings.

Technical Standard

 ISBN: 978-1-84219-840-7 .

The EPC defines the global energy rating on the basis of CO_2 emitted per unit floor area per annum. For residential buildings, this is compared to a series of reference values that are defined according to the climatic zone and the property type.

The official building energy certification procedure CALENER was developed by IDEA (Institute for Energy Diversification and Saving). The procedure has two versions, one for residential and small non-residential buildings, and the other for large non-residential buildings. The calculation engine for CALENER is the DOE-2.2 program developed by the Lawrence Berkeley National Laboratory and James J. Hirsch and Associates of the United States. The original DOE-2 program was developed in 1982 and predates considerably the CEN standards which define the calculation methods for the EPBD. The program simulates hourly performance of a building and can be compared to the detailed hourly dynamic simulation method defined in EN 13790.

Alternative certification procedures and software are acceptable once they are shown to produce equivalent results.

Implementation

The number of certificates issued is considered to be low, with under 2,000 certificates registered by the end of 2010 (Alvarez, 2011). The EPC is to be performed during the design phase, in order to obtain the building permit. The building energy rating is then confirmed on completion of the construction. The responsibility for compliance and control rests with the regional government.

Control

There are three different laws that could be applicable depending on which part of the regulations has not been fulfilled. If the building does not comply with the requirements specified in the CTE, the applicable law would be the Law 38/1999 for the Ordination of the Building Sector. In this case the different actors participating in the construction process are liable for the defects that compromise the stability of the building during ten years and for defects that compromise its habitability (e.g. insulation, service installations, etc.) during three years. This law obliges the firms or individuals participating in the construction to obtain insurance cover against the possible defects that could arise during the use of the building.

When the building installations do not comply with the requirements specified in the RITE, the applicable law would be the Industry Law (Law 21/1992) which states different penalties ranging from economic fines to suspension of activities.

If the EPC has not been issued according to the building project or the final building the applicable law would be the General Law for the Defense of Consumers and Users (Law 26/1984). This could result in administrative penalties which would not substitute the possible civil or penal responsibilities which will be applicable. The formulation and registration of an EPC does not imply the fulfilment of the CTE and the RITE (Molina and Alvarez, 2010) .

Compliance

Spain is the second of the two Mediterranean states currently undergoing infringement procedures in connection with the EPBD. In 2010, the European Commission formally requested Spain to comply with the directive. The Commission felt that Spain had not yet adopted a methodology for calculating energy performance or a certification scheme that covers all existing buildings and that the Spanish system for the inspection of boilers did not cover installations which existed before the legislation entered into force (IP/10/1561). In 2011, The Commission decided to refer Spain to the EU's Court of Justice for failure to fully comply with Directive 2002/91/EC on the energy performance of buildings (IP/11/1447). The Commission is maintaining that under Spanish law, the adopted methodology for calculating the energy performance of buildings and the requirements for handing over an energy performance certificate are applicable only to new buildings and existing buildings undergoing a major renovation, when the EPBD requires establishing a methodology and certificates for all types of buildings. Furthermore, the Commission considers that Spain still has not put in place the necessary measures to establish a regular inspection regime for boilers

6. Conclusions

Although there is considerable variety in the methodology of implementation of the EPBD in the four countries examined, it is quite clear that there are a number of common difficulties.

Evidently one of the major hurdles has been the actual transposition of the directive into national legislation, with two out of the four countries forming part of this study currently facing infringement procedures for failing to have done so completely, a full eight years after the enactment of the original directive. Whilst it would be presumptuous to assume a complete understanding of the reasons for this alleged failure to transpose the directive, the following could be considered as contributory factors:

- It is clear from all member states that the enactment of legislation for the definition of technical requirements is not straightforward. Despite their purportedly open and available procedures, both science and legality are experienced in popular culture as arcane, impenetrable and often un-interpretable (Silbey, 2008).
- The different requirements of the directive could be perceived to have different socio-economic priorities, and specifically the requirements for inspection of boilers and air conditioning systems were not considered as important as the articles relating to the energy performance and certification of buildings.

Implementation of the directive has been slow to commence, and none of the four countries can claim to have a high level of take-up of the requirement for energy certificates. Whilst this is sometimes considered to be a characteristic ‘southern problem’ of non-compliance with EU environmental law, this view has been found to ignore the general causes of implementation failure and non-compliance which arise from the nature and content of EU policies (Pridham, 1996). Case study on the implementation of different EU environmental policies has indicated that all states face

similar problems of compliance if an EU policy does not fit their legal and administrative structures (Borzel, 2000).

Clearly regional implementation in Italy and Spain is more complex to roll out and enforce than the single region approach taken in Malta and Cyprus, albeit for significantly smaller countries. Regional differences in implementation within a country may complicate enforcement and diminish the level playing field.

From a technical viewpoint the countries all made use of the CEN standards and/or existing technical solutions in order to develop the national methodology. Different approaches to compliance and control have been taken. The most demanding sanction is generally to obstruct the process of construction or utilisation of new or majorly renovated buildings by withholding the building permit. The effectiveness of this approach strongly depends on the type and scope of control. In view of the relative newness of the various certification systems, the effectiveness of the control systems cannot be assessed at this stage.

All member states are undergoing a review of their existing EPBD legislation in order to meet the new requirement of the EPBD recast. It is likely that the Mediterranean states can benefit as their relatively newer structures are more flexible to the modifications required by the recast. The authors are currently researching the different certification methodologies applied in Southern Europe (Malta, Italy, Spain, Cyprus) in order to establish whether these provide an accurately calculated value of energy demand in Southern Mediterranean housing. As outlined in the above paper, the application of these certification methods is relatively recent and with the implementation of the recast EPBD, and the revision of the CEN standards on which the methodologies are based, it is opportune to analyse the existing procedures and identify their strengths and weaknesses.

Planning Law in England and Wales: Sustainable Development and the Localism Debate

Julie Adshead[1]

[1]Salford Law School,

United Kingdom

Email: j.d.adshead@salford.ac.uk

Abstract:
At a time when 'localism' is very much on the UK government agenda, it is appropriate to reconsider the influences underpinnning planning law. Sustainable development has become a forceful legal principle and is expressly acknowledged in the planning regime of England and Wales and the shift towards more public involvement at a local level is now enshrined in legislation[1]. There are tensions apparent between previously identified ideologies and these newer phenomina. This paper examines the development and respective dominance of these ideologies. It also considers how the competing ideologies may fare, in the context of the climate change imperative and the current economic downturn.

Keywords:
Environment, localism, planning, public participation, sustainable development.

1 Introduction

The traditional title of the discipline 'Town and Country Planning' speaks of its origins and the notion that planning was, at its inception, primarily concerned with the control of urban development. The planning system in England and Wales certainly did not evolve with any acknowledgement of a role in environmental protection. Indeed, traditionally, environmental considerations were largely ignored. 'Town Planning' has more recently been defined as anything that 'relates to the character or the use of land'[2]. This exceptionally broad reach makes a powerful tool of the planning system. A tool, which has, over the years, increasingly served environmental interests.

Whilst acknowledging that environmental law and planning law are separate disciplines and distinguishing between pollution control and the planning system, the government sees the two systems as 'separate but complementary'[3]. It makes practical sense to recognise that these are interrelated disciplines (Owens, 1994 p 439), but the boundaries between the two are in reality fraught with complexity (Thornton, 2008 p 609). It is hard enough to reconcile the ideologies that underpin planning law (McAuslan, 1980)

 ISBN: 978-1-84219-840-7 .

and when environmental principles and ideologies are added to the mix, the tensions are even more clearly apparent.

Set the conflicting principles and ideologies against a scene that includes the urgency of the climate change imperative and economic crisis and an interesting picture emerges. In 1980, McAuslan identified three competing ideologies underpinning planning law; 1) The law exists to protect private property 2) The law exists to advance the public interest 3) The law should be used to advance the cause of public participation (McAuslan, 1980 p2). Since then, it is argued, two further significant ideologies have emerged; those of sustainable development and localism. These compete with each other and the traditional ideologies of planning law identified by McAuslan. This paper considers the development and respective dominance of the five ideologies over the period of existence of 'Town Planning' in England and Wales, concluding with an analysis of the current position and some thoughts on the implications for planning and the environment.

2 The Traditional Common Law Approach

The first of McAuslan's ideologies will be familiar to all legal scholars. It is an approach to the law which flows from the close relationship between private property ownership and the law. Historically the two have always been closely intertwined. The idea that the role of law was to uphold the constitution and property can be traced back to Locke in the seventeenth century (Locke, 1690). Until more recent times politics and law making were the exclusive preserve of property owners. It was also the case that the judiciary and lawyers were, themselves, owners of property and steeped in a legal tradition that long predated the advent of legislation and judicial intervention to protect the public good.

When faced with legislation enacted to improve the living conditions of the urban working classes and giving government powers to control the use of property, it is not surprising that land owners turned to the courts to protect their interests, nor that the courts were sympathetic to their cause (McAuslan, 1980 p3). It is in the principles developed by the courts in the late nineteenth and early twentieth centuries to protect landowners that the common law or private property ideology of McAuslan's can be recognised (see also Roberts, 1976 p5). The importance of preserving property rights continues to occupy a key position in planning law and policy as demonstrated by the presumption in favour of development enshrined in the new National Planning Policy Framework.

3 The Public Interest Ideology

Alongside the traditional common law approach another ideology has gained influence in recent times. The public interest ideology can itself be traced back in time to the writings of Bentham in the late eighteenth century (Bentham, 1780). This view of the law sees its role as one of providing legitimacy for action taken in the public interest (McAuslan, 1980 p4). Whereas the private property perspective can be recognised in the arguments of lawyers and decisions of the courts, the public interest ideology is evident in the actions and decisions of the public administrator. In order to serve the public

interest the law gives wide powers to administrators, which often give rise to conflict with the traditional rights of private property ownership. In more recent times, the courts themselves have come to recognise the legitimacy of administrative action in the public interest. With the advent of the twentieth century, lawyers and judges began to become familiar with the role of morality in law espoused by Bentham and this acceptance of the public interest ideology can be recognised in the case law of the higher courts in the early 1900s[4].

Planning law is characterised by legislation on land use planning that is motivated by the public interest ideology but yet often attempts to recognise the interests of private land owners (for example, by way of appeal against a planning determination). Planning disputes in the courts see a vacillation between the traditional common law approach and the recognition of the legitimacy of the actions of public officials in the interest of the public who act in good faith and are ultimately accountable to Parliament (McAuslan, 1980 p4 – 5). The conflict between these two ideologies proposed by McAuslan is by no means new and nor is it the case that the traditional common law approach has lost sway over the years.

4 Public Participation

The third ideology identified by McAuslan rests in the proposition that, inherent in the law, should be mechanisms for the public to be consulted and involved in decision making processes. Although, as McAuslan (1980 p5) notes, this ideology also has philosophical roots in the writing of J.S.Mill (1861), it has only become a recognisable force with its own constituency over more recent years. At the time of writing in 1980, McAuslan saw this ideology as of equal importance to the two outlined above, but as the least developed in terms of both policy and law (McAuslan, 1980, p5). As will be illustrated below, this third ideology has grown in substance in these respects in the past thirty years or so.

The basic premise of the principle of public participation in the context of planning law is that the public should have rights of participation in decisions on land use planning, not because of any property interests but in the interests of democracy and justice (Lucas, 1976). This notion naturally brings the ideology of public participation into conflict with the private property/common law approach. It also does not sit comfortably with the public interest ideology. Public administrators acting in the public interest in accordance with the law can tend to do so in a paternalistic way without necessarily allowing meaningful public participation in their decision making.

4.1 The Development of Public Participation

The public participation ideology is worthy of further attention here on a number of counts. Whereas what is meant by the private property and public interest ideologies is quite clearly understood, the meaning of public participation is less so. Also, as mentioned previously, there have been significant developments in both policy and legal terms since 1980. This has particularly been the case in respect of environmental

[4] *Board of Education v Rice* [1911] AC 179; *Local Government Board v Arlidge* [1915] AC 120.

matters and it is through the lens of environmental sustainability that this paper views the planning regime.

4.1.1 The Spectrum of Public Participation

Public participation can range from transparent procedures at one end of a spectrum to direct involvement in law-making and even litigation[5] at the other (Lee, 2003 p113). McCracken and Jones (2003) place participatory activities into three categories; 'proactive' (for example, environmental impact assessment), 'active' (for example, the keeping of registers and responding to requests for information) and 'passive' (for example, data monitoring and publication via the internet). Whilst Black (2000) identifies a range of participation extending from 'thin' such as transparent procedures and traditional consultation exercises to 'thick' encompassing deliberation and consensus based decisions and solutions. Thus, it is possible to identify a ladder of public participation (Arnstein, 1969) as illustrated below;

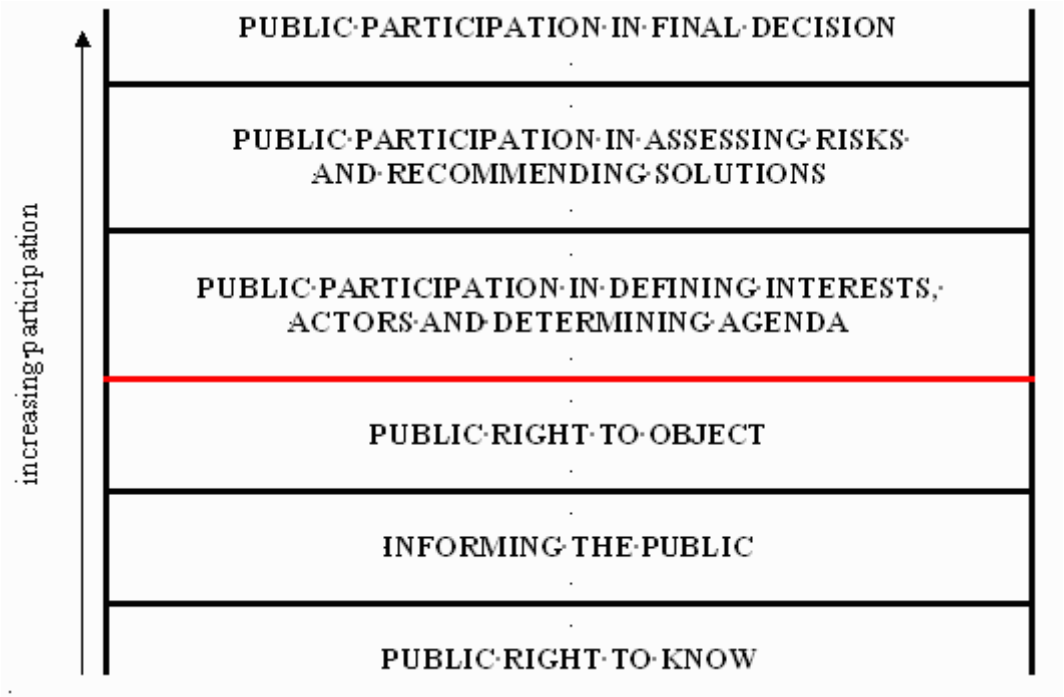

Figure 1. The Public Participation Ladder
(Adapted from Wiedemann and Femers, 1993)

It is clear that the greatest areas of conflict between the public participation ideology and those of public interest and private property will arise with the types of participation towards the top of the ladder. Private property interests will not wish to see affected members of the public involved in decisions relating to their property and nor will public administrators wish to devolve their decision making powers to the uninformed public.

[5] By way of judicial review of a public body's decision.

4.1.2 The Entrenchment of Public Participation in Law and Policy

Whereas at the time of McAuslan's writing, the public participation ideology was arguably underdeveloped, it is now very much a part of overarching law and policy at both supranational and national levels. Freedom of information in environmental decision-making, an essential pre requisite and cornerstone of public participation, has been a feature of EU Law since a 1990 Directive[6]. Since this time, there has been a series of EU Directives containing provisions for procedures informing or enabling the public. Furthermore, public participation is a recurrent theme in EU policy making and this can be noted in the Environmental Action Programmes as well as the EU Governance White Paper[7].

One of the most significant recent developments in the field of public participation is the Aarhus Convention[8]. The Convention implements principle 10 of the Rio Declaration on the Environment and Development and is commonly described as comprising of three pillars, public access to environmental information, public participation in environmental decision-making and public access to justice in environmental matters. The Aarhus Convention goes beyond pre-existing legal provisions and traditional procedures for the provision of information and consultation in quite a number of ways. In particular, the Convention provides for a broad range of decisions requiring the participation of the public. It is clear that the spirit of Aarhus is one of banishment of secretive decision-making and the provision of real opportunities for the meaningful engagement of the public, resulting in tangible input into the ultimate decision.

Both the European Union and the UK have implemented the Convention. It is clearly the case that planning law in England and Wales falls within the remit of the Aarhus Convention and despite the fact that there is some doubt cast on the adherence of UK planning law and procedures with the convention (Purdue 2005), the public participation ideology is now well-established in this context. Public participation in the planning process manifests itself in two areas; in plan development and in development control. At the plan development stage public participation was evident as early as 1968 when the 'new style' development plans were adopted and is present today in the participation opportunities offered by the forum of the Public Examination. In terms of development control, public participation remains central to Part I of the Town and Country Planning Act, 1990 (Miller, 2002 p7) and can be recognised in publicity requirements and opportunities for the public to make representations as well as in Public Inquiries into major projects. Furthermore new mechanisms for more participatory and deliberative process have been mooted and trialled in, for example, waste site plans. These include Citizens' Juries and Community Advisory Committees (Petts, 2002 p193).

[8] Convention on Access to Information, Public Participation in Decision-making and Access to Justice in Environmental Matters, Aarhus, Denmark, 25 June 1998 (entered into force 30 Oct. 2001).

5 Sustainable Development

It is argued that since 1980 further key ideologies have developed that are influential in planning law and procedure. In the past thirty years or so, the principle of sustainable development has become prominent in all areas of law making. Whilst there remains some debate surrounding the legal enforceability of the principle (Bell & McGillivray, 2008 p 60. Hendry, 2005), it is submitted that there is an increasingly dominant viewpoint that the purpose of law (particularly in the environmental and planning spheres) is to ensure sustainable development.

5.1 The Emergence of Sustainable Development

The sustainable development ideology is rooted in more recent times. The principle can be traced back to the 1972 United Nations Stockholm Conference on the Human Environment, but its most commonly accepted formulation derives from the 1987 Bruntland Report;

'Development that meets the needs of the present without compromising the ability of future generations to meet their own needs'[9].

5.1.1 The Meaning of Sustainable Development

What the principle means has been the subject of long debate (see for example, Stallworthy, 2002, Owens and Cowell, 2002, 2011). It is notably anthropocentric, looking primarily to the needs of mankind rather than the environment, flora, fauna and ecosystems and strives for equity both between current and future generations. There are three (often conflicting) interests to balance in attaining the goal; the environment, society and the economy. The principle is often broken down into four key components; inter-generational equity, sustainable use, intra-generational equity and integration. This latter element is one of the most problematic, particularly in terms of integrating environmental and economic policy (Gibbs *et al*.1996, 1998).

[9] Report of the 1987 Wold Commission on Environment and Development 'Our Common Future' (The Brundtland Report).

 ISBN: 978-1-84219-840-7 .

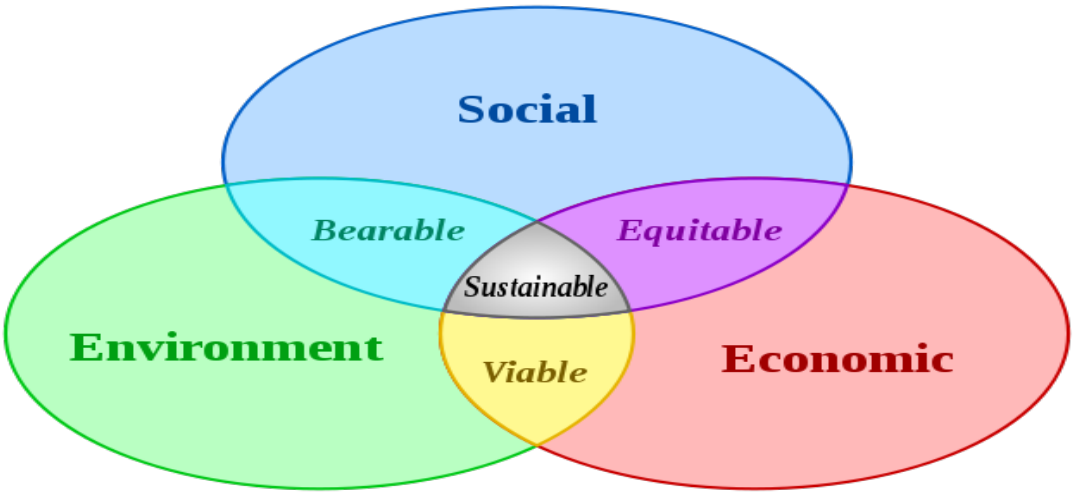

Figure 2. Sustainable Development
(Adapted from Johann Dréo, 2006)

Pure proponents of sustainability argue that the two component terms of the principle represent an oxymoron in that development can never be sustainable. Those who favour a strong application of the principle of sustainable development maintain that the principle does not allow for any diminution of our natural resources, whereas those arguing for a weak version of the principle maintain that resources can be replaced and technological solutions for provision for future generation can be found (Jacobs, 1999). As Owens and Cowell (2011) note in their follow up publication to the seminal work on sustainability and planning (Owens and Cowell, 2002) 'interpreting sustainability could never be a formulaic or purely functional matter: it involved ethical and political choices over which people frequently disagreed'.

5.1.2 The Entrenchment of Sustainable Development in Law and Policy

The arguments surrounding the essence, achievability and legal force of the principle continue to be rehearsed aplenty, but what is evident is the fact that sustainable development has found its way into law and policy at all levels over the past 30 years. The principle is enshrined in the Rio Convention in its Agenda 21[10] and has a prominent place in the EU Treaty;

'The Union shall establish an internal market. It shall work for the sustainable development of Europe based on balanced economic growth and price stability, a highly competitive social market economy, aiming at full employment and social progress, and a high level of protection and improvement of the quality of the environment. It shall promote scientific and technological advance.[11]'

[10] Earth Summit, 1992.
[11] Art 3 (3) TEU.

In England and Wales, sustainable development constitutes the principle aim of the Environment Agency[12] and it is firmly ensconced in policy terms, through both the development of a national strategy[13] and local Agenda 21 initiatives. Although there is an acknowledged close relationship between environmental law and planning law (see earlier), there is no overarching obligation to take into account environmental considerations in the planning process. Environmental considerations can be material, particularly if a conservation site is involved or EU law principles prevail. However, sustainable development has been an integral part of planning law for some time.

Section 39 of the Planning and Compulsory Purchase Act, 2004 states that all plan making bodies are to exercise their functions 'with the objective of contributing to the achievement of sustainable development'. In addition two of the key former Planning Policy Statements provided guidance on sustainable development in planning[14]. In a highly controversial move, the new coalition government has now introduced a presumption in favour of sustainable development in the new National Planning Policy Framework (NPPF)[15]. The NPPF definition of sustainable development reflects the Bruntland definition (above) within a planning context. It is articulated as 'planning for prosperity, for people, and for places'. Thus it embraces the economic, social and environmental elements of the Bruntland formulation (Brearley, 2012).

6 Localism

McAuslan (1980) identified public participation as an emerging yet important ideology. It is argued that, in the second decade of the 21st century, another such developing ideology is identifiable. Although it has a close relationship with public participation, localism is a separate concept. Whereas public participation refers to the involvement of the public, to varying degrees, in decision making at a number of levels; it is argued that localism is concerned with where decisions are made. It is in fact an iteration of the principle of subsidiarity, embraced by the European Union over recent years. In simple terms, the principle dictates that decision making should take place at a level where it is most effective and that decisions should only be made at the higher level when this is to best effect. The principle also has its roots in philosophy and can be traced back to Aristotle and St. Thomas Aquinas as well as being recognisable in the nineteenth century in the work of Proudhon (1863) and J.S. Mill (1861). Mill's view was that 'It is but a small portion of the public business of a country which can be well done, or safely attempted by the central authorities'.

6.1 The New Localism

The localism agenda is very much at the forefront of the current UK coalition government's policy. Support for deregulation and liberalisation have been apparent in Conservative Party policy from the 1940's onwards and this traditional support for economic liberalisation is now coupled with a decentralising ideology (Bullock, 2011). In July, 2010, the Department for Communities and Local Government (DCLG)

[12] Environment Act, 1995 s4.
[13] National Strategy on Sustainable Development (HMG, 1994).
[14] Planning Policy Statement 1 (2005) Delivering Sustainable Development; Planning Policy Statement 9 (2005) Biodiversity and Geological Conservation.
[15] National Planning Policy Framework, March 2012, Department for Communities and Local Government.

 ISBN: 978-1-84219-840-7 .

announced; 'Our ambition is localism. Real change driven by local people working together in their communities'. A radical reform of the planning system was promised with the devolution of greater powers and a return of decision-making powers on housing and planning to local councils[16].

A Decentralisation and Localism Bill was forthcoming and in due course the Localism Act received Royal Assent on November 15, 2011. The DCLG maintains that the Act 'will trigger the biggest transfer of power in a generation'. There are a wide range of planning- related measures in the Act, including the introduction of a new right for communities to draw up a neighbourhood plan, a community right to build and the requirement to consult communities before submitting certain planning applications. The Act also gives the government power to require that money raised from the Community Infrastructure Levy goes directly to neighbourhoods. In addition the Act abolishes regional strategies and the Infrastructure Planning Commission (previously responsible for nationally significant infrastructure projects).

Localism is clearly of importance to the government of today in the United Kingdom, but it is not a new ideology. Ideas of decentralisation and decision making taking place at the most effective (and most local level) have existed over a long period of time and many policy areas have vacillated between central control and decentralisation over the years. Important questions surround just what is 'local' in the current thinking. Rhetoric seems to suggest it refers to quite small scale local community groups but what of local government and regional bodies? The concept of localism is now explicitly recognised in both the name and content of legislation as well as in the significant new National Planning Policy Framework. It will no doubt have a role to play, both in future legislative provisions and in the courts. It could be posited that a purpose of law in the planning sphere is now the decentralisation of decision making or in the current government's language, returning power to the people (Le-Las and Shirley, 2012).

7 Contemporary Influences

If it is accepted that there are now five recognisable ideologies that influence planning law, then a yet more complex picture emerges of how these conflict with each other. Some initial observations on this are put forward in the conclusions below. It would seem reasonable to suppose that the respective dominance of one ideology at one given time will be subject to external factors and pressures. For example, as suggested above the powerful force of property ownership may explain an era characterised by private interest in the nineteenth century, whilst the modern administrative state gained influence in the post-war period allowing the public interest ideology to surface. (Le-Las and Shirley, 2012). A general rise in environmental consciousness has also, no doubt, shaped the growing trend towards public participation. There are two contemporary issues that are worthy of examination in terms of their influence on the complex balance between the underpinning ideologies. These are climate change and the economic crisis.

[16] Department for Communities and Local Government, Draft Structural Reform Plan, July 2010.

7.1 Climate Change

Whilst the recognition of the possibility of climate change is not new (The Royal Commission on Environmental Pollution referred to global warming in its first report of 1971), it is only more recently that the problem has been widely acknowledged as an imperative for action. The most recent report of the IPCC (Intergovernmental Panel on Climate change) finds that there is a greater than 90% chance that increases in global temperatures are man-made[17]. Although scepticism and debate continues, action has been taken at international, regional and national levels.

The Kyoto Protocol to the UN Framework Convention on Climate Change[18] sets binding targets for green house gases for the developed nations and the EU has set even more stringent targets for its member states. A new package of legislation published in 2009 implements the EU targets of producing 20% of energy from renewable sources, 20% reduction in green house gas emissions and 20% reduction in primary energy use by 2020. At national level, the UK Climate Change Programme was launched in 2000 to meet the green house gas emission reduction targets and the UK also introduced its own goal of reducing carbon dioxide emissions by 20% on 1990 levels by 2010. In 2008, the UK became the first nation worldwide to introduce a legally binding long term framework to cut carbon emissions. The Climate Change Act, 2008 imposes a statutory duty upon the Secretary of State of 2050 'to ensure that the net UK carbon account for the year 2050 is at least 80 per cent lower than the 1990 baseline'[19].

On the face of it, the climate change imperative would seem to be most influential in promoting the sustainable development ideology. Indeed, this is probably the case and not just in promoting the environmental limb of the principle. As noted by Owens and Cowell, (2011 p2) facilitating certain types of development (for example wind farms) is crucial to countering climate change. The relationship between the centralism/decentralism debate and the thrust to meet carbon emissions targets is, on the other hand, by no means clear cut. On the one side, government appears to favour central control to enable the ambitious targets to be met (for example by legislating for central binding targets and using the building regulation framework to control emissions from buildings) and on the other to encourage local community initiatives and incentive-based policies, for example, for renewable energy. Walter (2012) questions how the central steering of renewable deployment will meet the carbon budgets without targets for local authorities and doubts that the government's dual commitment to both onshore wind and localism can be achieved.

Similar uncertainties surround the impact of the climate change imperative upon the traditional ideologies of private property and public interest. The conflict between the two ideologies is arguably eroded when private property interests in development of land, for example for wind farms, could also serve the public interest in reaching targets and averting climate change. Conversely, private property interests of a 'NIMByist' character could gain the support of the law and mean a strengthening of the traditional

[19] Section 1.

common law approach as well as being detrimental to the climate change project and the public interest.

As noted above, the public participation ideology has grown in strength over the past thirty years and procedures for participation are now inherent in the planning process. On the one hand this could be seen to benefit the climate change agenda by harnessing local knowledge and resulting in better decision-making. However, fast action is required to avert global warming and there is some doubt as to whether any speeding up of the system can be accompanied by enhanced public participation (Brearley, 2012). Thus the impact of the climate change imperative upon the public participation ideology is also uncertain.

7.2 The Economic Crisis

The period from 2008 to date has seen a global financial crisis not encountered since the Great Depression of the 1930's. The UK has responded with punishing austerity measures and the economy has now slipped into a double dip recession. It is inevitably the case that in such pressing times when the public is subject to immediate or imminent hardship, goals such as addressing the climate change issue and involving the public in decision making may seem to hold less importance. The imperative of stimulating economic growth is bound to be paramount. Fundamental to this will, of course, be vigorous efforts to encourage and reinvigorate development. The UK Government's March 2011 budget[20] and the parallel *Plan for Growth*[21] identified the planning system as one of the five key restrictions on growth in the UK and measures to change the planning system to address this have already been introduced in the Localism Act[22]. The pressure brought to bear by attempts to pull the nation out of recession and address the financial deficit has already brought notable shifts in the balance between the ideologies identified above.

As previously noted, there are two facets to the private property ideology. One manifestation is in the protection of the rights of private property interests to develop their land and the other is in the protection of property owners from unwelcome adjacent development. The controversial introduction into the new National Planning Policy Framework (NPPF) of a presumption in favour of sustainable development, it is argued, signifies a shift towards the first of these manifestations of property interests. This, no doubt, is primarily a response to the need to facilitate development mentioned above and it is predicted that this provision will mean a presumption in favour of development in almost all cases. According to the NPPF, this is to be the case unless the adverse impacts of doing so would significantly and demonstrably outweigh the benefits[23]. The Secretary of State has already signalled the government's intention to give significant weight to growth in planning decisions (Bullock, 2011). Some are of the view that the consequence of the new presumption will be the erosion of the second manifestation of the property ownership ideology as this is subsumed into the public good (Brearley, 2012). In other words, development will proceed regardless of the

rights of private property ownership where this is in the public interest and clearly development in the current economic climate would seem to serve the public interest.

This leaves an interesting position in respect of the private interest versus public interest nexus. Whilst one element of the property ownership ideology has been strengthened, the public interest ideology has also gained in force at the expense of those property ownership interests affected by proposed developments. On the face of it, the introduction of the presumption in favour of sustainable development would seem to strengthen the sustainable development ideology. However, it is clear from the *Plan for Growth* that the presumption should be interpreted as usually providing the go ahead to all forms of development. Questions of a social or environmental nature appear to be secondary. This is recognisable in the watering down of the zero-carbon definition, for example (Ellis, 2011).

As its name suggests, the Localism Act, on the face of it, promotes the decentralist ideal. Government saw it as essential to attaining the investment and growth necessary to emerge from the recession to move away from the centralised bureaucratic planning system to the 'bottom up' approach of 'Open Source Planning'[24]. As mentioned above, the Act contains a list of measures aiming to give local communities a greater voice in planning issues. However, tensions are already emerging between this localism system and the need for growth as articulated in the recently published government plan (Bullock, 2011, Clark, 2011). There is always the possibility, that the effect of the Act, far from improving the system and enhancing growth, will in fact hinder development by providing traditional Tory voters in the party's rural heartlands the opportunity to use it as a NIMBY charter (Bullock, 2011). Whether or not this is the case as Bullock (2011) notes 'localism and growth can make uneasy bedfellows'. Certainly, at first blush, the Act promotes the ideology of localism to new levels. However, the procedures therein are complex and it remains to be seen how many local communities take up the opportunities to be involved in the planning process. As Clark (2011) points out, the Act raises numerous practical issues that will place additional pressure on local authorities and developers at a time when resource is limited. Whether, in fact, the new measures will lead to any real entrenchment of decentralisation in the law remains to be seen.

As responding to the imperative of climate change requires fast movement, so it is argued, does action to stimulate economic growth and development. Thus it may be that lengthy and unwieldy public participation procedures will also suffer in the quest for economic recovery. This trend is already recognisable in the new provisions for major infrastructure projects in the 2008 Planning Act and it is likely to be accentuated by the abolition in the Localism Act of the Infrastructure Planning Committee and the allocation of its functions to the Planning Inspectorate.

[24] Conservative Party, *Open Source Planning* (London, February 2010)

8 Conclusions

This paper forms just the start of a larger research project. A framework has been identified to apply to further examination of planning law and policy. At the time of McAuslan's writing, the public participation ideology was newly emergent and weak. McAuslan (1980) considered a number of areas of planning law in coming to his conclusion, which, in summary, was that the private property and public interest ideologies worked together to maintain a *status quo* always ultimately framed in the terms of private property and that the future for the development of participative democracy was somewhat bleak (McAuslan, 1980 p145, p274).

There can be no doubt that the public participation ideology has grown in strength significantly over the past 30 years. In addition the related but separate ideology of de-centralisation, or localism, has come to the fore and is now readily recognisable in legislation. The ideology of sustainable development in many respects plays out the conflict between private interest public interest and public participation. These three conflicting ideologies can be mapped against the three pillars of sustainable development; economic, social and environmental. What is clear, however, is that the principle of sustainable development now has its own separate manifestation as a goal of law.

Also self-evident is the fact that prevailing imperatives and pressures will influence the balance between the conflicting ideologies. In this paper just two such contemporary influences (climate change and economic crisis) have been considered and some tentative suggestions have been made as to how the respective positions of the previously identified ideologies might be shaped by these external factors. The next stage of the project will be the selection of certain specific areas of planning law and policy. Then, following in the footsteps of McAuslan, these will be examined in depth utilising the extended framework developed in this paper. The ideologies referred to here can be recognised as underpinning many areas of state regulation. The conflict between them is identifiable in environmental regulation as well as in housing, public health and health and safety law. The focus, for the moment, will be upon planning, but, as here, the analysis will be conducted very much through the lens of environmental protection. It is predicted that an interesting, if complex, picture will emerge.

Regulatory challenges of building CCS pipelines for cross-border transportation

Inga-Liisa Paavola[1]

[1]Environment and Energy Law, Faculty of Law
University of Helsinki, Helsinki
Finland

Email: inga-liisa.paavola@helsinki.fi

Abstract:

Carbon dioxide capture and storage (CCS) is a relatively new technology in the context of climate change mitigation strategies. Its legal and regulatory implications are not yet wholly developed. It is essential to identify legal gaps and obstacles that still need to be addressed. There are challenges raised in the field of building regulatory issues as well: these include for example regulation of transport. This paper takes a brief comparative look at the regulatory principles, especially in the European Union (EU) from the point of view of CCS favourable regulating instruments when trying to support CCS technologies. Remarkable legal developments and creating an effective fit for purpose regulatory regime are crucial steps towards to the more large scale utilization of CCS and cross-border transport of CCS.

Keywords:
CCS, regulations, pipelines, cross-border transportation

1 Introduction

1.1 CCS Regulative Basis and Objectives

In the 2007, CCS was accepted as a climate change mitigation option within the Kyoto Protocol[1]. In addition, legal barriers to the storage of CO2 in geological formations under the seabed have been removed through modifying the London Protocol and the OSPAR Convention. In 2006, amendments to the London Protocol allowed and regulated the storage under the seabed of CO2 from capture processes. In 2007, the contracting parties under the OSPAR Convention also adapted amendments that allowed the storage of CO2 under the seabed. The EU Directive (Directive 2009/31/EC) on the geological storage of CO2 was adopted by the European Council on April 6, 2009 and entered into force on June 25, 2009. The Directive sets out a regulatory regime for permitting of exploration and storage. The Directive applies to projects with

[1] The Kyoto Protocol. Adopted in Kyoto, Japan, on 11 December 1997;entered into force on 16 February 2005. The United Nations Framework Convention on Climate Change.Produced at the United Nations Conference on Environment and Development in Rio de Janeiro from June 3 to 14, 1992.

intended storage of more than 100 ktonnes of CO2. The Directive gives Member States until 25 June 2011 to transpose it into their respective national laws.

The aim of the project is to study the requirements for the development of a large-scale CO2 transport infrastructure in Europe, between 2020 and 2050. The most important conclusions are related to the finding that the EU CCS transport infrastructure is to be led by a relatively small number of countries, who share the largest burden in the areas of CO2 capture, transport and storage. These include the countries bordering the North Sea, and those countries relying heavily on coal or lignite for their power supply (Germany, Poland the Czech Republic). It is crucial that these countries take the lead and are supported to do so, not only now, but during the whole CCS infrastructure development.[2]

The objectives of CCS are clear: CCS must be able to safely sequester large amounts of carbon dioxide (billions of tonnes) for a long time (hundreds to thousands of years). In order to abate atmospheric CO2, CCS should maximise CO2 emissions avoided. To achieve these objectives, CCS regulation must:
- Establish a framework encouraging responsible operation and investment;
- Balance stability and predictability with flexibility and adaptability to new scientific information;
- Provide ease of implementation for both regulators and industry.

CCS regulation must manage the risks and liabilities of CCS, distinguishing between risks that should be assumed by the operator, those that can be mitigated through regulation, and those that can be transferred. However, risk and liability are not the only drivers for CCS regulations. Issues related to competition, climate regime commitments, tax policy, financial responsibility, property rights and international treaties will also shape the CCS regulatory framework. For some risks, the most stringent rules may not come from government at all, but instead from the private sector, such as the insurance industry.[3]

1.2 CCS Regulative challenges in Practise

For practical implementation, CCS will need to be regulated as an industrial process, with regulations geared to each project stage: capture, transportation, site selection and permitting, site operations, site closure, and long-term stewardship. While all the elements of this industrial process exist, they are not yet developed to scale nor are they integrated. The structure of the future CCS industry could take a number of possible forms in terms of the relationships between CO2 producers, CO2 pipeline operators, and geological storage site operators. This policy brief does not cover regulatory issues related to capture but it is worth noting that, while the long-term potential for CCS lies in capturing CO2 at fossil-fired electric power plants, significant short-term potential lies in other industrial processes that already generate a concentrated CO2 stream, such as natural gas, ammonia, or hydrogen production. Regulation of transport and geological storage must be designed to manage CO2 from both electric utilities and

[2] European Commission: Developing a European CO2 transport infrastructure (2011).
[3] Roggenkamp, M., Haan-Kamminga, A.: Transportation of CO2-Legal Considerations. In book "Carbon Capture and Storage, Emerging Legal and Regulatory Issues"(2011). Oxford and Portland, Oregon. P.107-122.

from these other industries. As each CCS project site will be unique, the characterisation and management of geological and technical uncertainty – shades of grey as opposed to black and white – requires methodologies and technologies tailored to the particular circumstances and risks of each site.[4]

1.2.1 Site characterisation

Careful site selection is the single most important way to manage short- and long-term risks of CCS. Establishment of generalised CCS siting guidelines that can be customised to local geology is an important first regulatory step that can be immediately undertaken. Such efforts are underway in Australia,
the US, Canada, and throughout the EU. The site characterisation phase will extend into site development. Installation of injection wells and monitoring systems will add detailed understanding of site geological features.

1.2.2 Site operations

Regulation of site operations will centre on pipeline transport, injection, and monitoring. Most CCS projects will require pipeline transport from source to sink. Regulatory requirements regarding injection will shape the industry by specifying parameters such as injection well design, allowed injection quantities, reservoir pressure limits, purity of CO2 stream, and financial responsibility standards. Current regulations cover some of these, but modifications are needed to adequately manage the risks of injecting large volumes of buoyant CO2. Additionally, monitoring must verify that sites are performing as expected. Establishment of general monitoring and verification (M&V) requirements will be useful to both industry and regulators
but, given the heterogeneity of both capture systems and geology, each site's M&V regime will need to be site-specific and adaptive over time. Extensive baseline measurements before injection will be essential. Technical requirements will not be the only driver for M&V regulations, as the monitoring of results is also important for public acceptance. Large-scale CCS deployment cannot proceed until extensive pipeline infrastructure is in place. Large volumes of CO2 – a 1,000 MW coal-fired power plant produces 5 to 8 million tonnes of CO2 annually – will need to be transported from source to sink. Linkages are complex, and the business model for pipeline operators includes significant risk, as their operations are subject to uncertainties beyond their control at both ends of the pipe. This risk puts upward pressure on pipeline costs, as do recent steel price increases. Transport infrastructure investment requires regional and site-specific knowledge of geological storage prospects, as well as knowledge of current and future CO2 source locations, volumes, and characteristics.

Regulation of risks related to pipeline transport is straightforward, but more complicated regulatory decisions will relate to funding, siting and construction of pipeline networks off-shore, onshore, and through urban zones, natural monopoly concerns, and issues of eminent domain. Different regulatory models for CO2 pipeline ownership, a privately owned, common carrier approach or a public utility approach could stimulate different

[4] International Risk Governance Council: Regulation of Carbon Capture and Storage (2008, Genova). http://www.irgc.org/Expertcontributions-and-workshop.html. P.8-15.

levels of investment, potentially influencing the ultimate organisational structure of the CCS industry.[5]

2 Co2 Transportation Methods and Needed Regulation

Captured CO2 can be transported by various means including pipeline, ship, road, tanker or railway car. The key regulatory considerations for CO2 transportation include:
-Health, safety, civil and environmental protection in the event of CO2 releases during transportation
-Allocation of liability in the event of damage resulting from CO2 releases
-Pipeline re-use, routing/corridor requirements and acquisition of rights-of-way.
-Trans boundary transport of CO2.

For all other aspects, it will be important to consider how existing regulations apply to analogous activities such as natural gas transportation. It is likely that many of the regulatory considerations described will already be covered by existing health, safety and environmental protection laws relating to such activities and/or could be conferred onto CO2 pipeline development and operation through modifications to existing laws. Operational and commercial differences between CO2 supply and transportation, and natural gas supply and transportation should also be understood so that any new regulations for CO2 transportation are appropriately adapted to the underlying characteristics. Therefore, it is vital to analyse current regulations and industry operations to assess whether they will already apply or whether they need to be modified. The main areas for consideration will include:
- Existing laws relating to occupational health and safety, in particular those industries currently using CO2 (*e.g.* industrial or oil and gas operations).
-Existing laws relating to civil protection, industrial pollution and corporate liability (*e.g.* petroleum/mining laws; major accident hazard prevention laws).
- Any development rights allowed under existing gas transportation regulations (*e.g.* the types of procedures and determinations that are already allowed, for which size of pipelines and for what types of transported fluids.
-Existing planning directives and environmental impact assessment (EIA) procedures relating to pipeline or other major infrastructure projects, including EIA requirements.
-Emissions accounting requirements (*e.g.* monitoring, reporting and verification) under emissions trading programmes or other incentives schemes if applicable
-Laws relating to the reuse of pipeline infrastructures or decommissioning (*e.g.* petroleum laws).[6]

3 EU Jurisdiction of Pipelines of Impact on the Environment

3.1 International Law Background

The pipelines transporting CO2 from the capture installation to the storage facility may cover long distances, as emitters and storage facilities often are situated far from each

[5] International Energy Agency (2010).Carbon Capture and Storage Model Regulatory Framework. http://www.iea.org/ccs/legal/model_framework.pdf P. 35-55.
[6] OECD/IEA (2010).Carbon Capture and Storage Model Regulatory Framework.

other. Whereas states have sovereignty regarding their territory and territorial waters and may apply and enforce all necessary rules and regulations in these areas, they only have sovereign rights over the continental shelf and economic zone. Following the united Nations Law of the Sea Convention of 1982 (UNCLOS 1982), these sovereign rights relate, if an EEZ has been established, to the need to explore and exploit natural resources and to the economic use of the zone relating to the production of wind or wave energy. In addition, UNCLOS 1982, in Article 87c, also explicitly provides for the freedom of the laying of pipelines.

Although neither the CCS Directive nor UNCLOS 1982 explicitly states that CO2 pipelines are to be considered to be subject to a coastal state's sovereign rights and functional jurisdiction, the wording of UNCLOS 1982 does not exclude such interpretation. If the right to regulate is not a direct consequence of the right to regulate the production and transportation of natural resources such a right may derive from the more broadly phrased right to regulate specific economic activities relating to the energy sector. state is still entitled to apply specific rules to protect the environment and national health and safety. So, whereas the states have the exclusive right to regulate the construction and use of co pipeline onshore, their legislative jurisdiction may be more limited offshore. However, they at least retain the right to regulate the protection of the environment and national health and safety.[7]

3.2 EU ETS Regulation

The EU-ETS[8] is the mechanism by which the EU may create the financial basis for CCS projects. However, the price of CO2 emissions is not expected to increase sufficiently rapidly to render CCS commercially feasible. Additional mechanisms should be put in place to support the development of CCS projects after the first wave of demonstration projects. To further increase the attractiveness of CO2 transport projects for investors, EU coverage for financial guarantees is recommended.

3.3 EIA Regulation

The CCS Directive Recital 17, article 31 requires operators to apply for an environmental impact assessment (EIA) covering the construction and operation of CO2 pipelines. The EIA shall identify, describe and assess the direct and indirect effects of a project on human beings, fauna and flora, soil, water, air, climate, landscape, material assets and cultural heritage and the interaction between these factors. These requirements must be implement in national legislations and procedures. These national requirements may go beyond the provisions in the EIA Directive[9]. It also means that the public will be involved in the process of granting permits for the construction of pipelines The EIA Directive requires that the members of the public affected by or having an interest in, the construction and use of pipelines are informed and able to participate in the decision-making process.

[8] European Union Directive (2009/297/EC) to improve and extend the greenhouse gas emission allowance trading scheme of the Community.
[9] European Union Directive (85/337/EEC) on Environmental Impact Assessments.

3.4 Environmental Damages Regulation

The CCS Directive recognizes the need to protect the environment from the damage resulting from CCS. Article 34 of the CCS Directive provides for an amendment of Environmental Liability Directive (ELD) to ensure that adequate provisions are made regarding liability for damage to environments resulting from any failure of permanent containment of CO2. In principle, only the storage of CO2 is covered by the ELD under the CCS Directive, thereby guaranteeing compensation by the operator for environmental damage on the basis of regime of strict liability. However, this applies to subsoil storage of CO2 only. Transport is not included in Annex III of the ELD.

Leakages and impact on climate change

The purpose of CCS Directive is to avoid co emissions through permanent storage, any leakage of CO2 should be avoided. The CCS Directive therefore amend the EU Emissions Trading System Directive (EU ETS) to stage that stored co is not considered to have been emitted and also introduces regime of corrective measures in case of leakages. The CCS Directive brings the transport of CO2 under the EU ETS in the year 2013. Under the amended EU ETS, the operators of pipelines need to apply for an emissions permit. Article 4 of the EU ETS requires Member States to ensure that all installations listed in Annex I have permit authorising them to emit greenhouse gases.[10]

4 Cross-border transport

Based on the location of storage sites around Europe, it is concluded that that a large fraction of pipeline infrastructure will cross Member State boundaries. International cooperation will be essential to ensure that technical solutions to the managed flows of CO2 are cross-border compatible. This co-operation is also required to ensure that sufficient transport capacity is available to accommodate the increasing CO2 flows that would occur as a pipeline route traverses industrial regions on its way to a storage area. A central issue is the liability for stored CO2, which needs to be arranged between Member States. An amendment in 2007 to the 1996 London Protocol allows for the sub-sea storage of CO2 and its cross-border transport. This will provide the conditions for developing the vast storage capacity in the North Sea. However, the amendment remains to be ratified by most of the Contracting Parties and will not come into force for some time. An interim solution to this problem must be sought by Europe with some urgency.

A key issue that should be regulated before more complex CCS networks arise is the liability for transported, as well as for stored CO2. The EU Storage Directive stipulates that the storage operator will be liable for leakage over a significant period after injection. In addition, the liability is against future emission allowance prices, rendering the risk unknown and potentially large. In a one-on-one network, the financial backing for such a risk might be available. In a more complex network, with multiple suppliers

[10] European Commission, Guidance on Interpretation of Annex I of the EU ETS Directive: ec.europa.eu/clima/documentations/ets/guidance_interpretation_en.pdf. Viewed: 28/04/2012.

and more than one storage provider, as well as in international networks, the liability issue poses a threat to their development and will need to be resolved beforehand.[11]

5 Challenges and opportunities of CCS and Transportation

Safe and cost-effective transport of captured CO2 to storage sites is still essential challenge. Pipelines are in use in the USA and Turkey to transport CO2 for enhanced oil recovery and in the future these are likely to be the most viable option for transporting captured CO2 within Europe, though shipping may also have a role to play.

The energy sector usually distinguishes between several types of pipelines, like upstream, transportation and distribution. Each category of pipelines may be subject to a different set of rules applying to their construction and use. In the EU, as part of market liberalisation policy, the organisation of the use of gas pipelines has received considerable attention during the last two decades. In particular, the third party access has proven to be a central instrument in the development of a liberalised energy market. The major question is whether the qualification or distinction used in the energy sector can also be applied to co transportation systems, so that it may benefit from the lessons learned in regulating the use of energy pipelines. In case of CCS, a CO2 pipeline will connect a producer of co with a consumer or receiver of co. Considering that a pipeline is directly linked to the reservoir, it may be argued that co pipelines should be considered as some sort of reversed upstream pipeline system. Consequently these CO2 pipelines could be already governed by national laws and this would mean that the regimes applying to the use of upstream pipelines could be applied.

Additionally, the public acceptance is closely linked to the safe and environmentally friendly operations of both the transportation and storage of CO2. Unsafe transportation can result in damaged pipelines, leading to leakages that harm the environment in general. A comprehensive safety regime is in place and it can be expected that certain amendments need to be made to facilitate co transportation.

What is more, the issue of transportation of co gets more complicated if having cross-border operations. Cross-border CCS chains raise the question of the extension of states responsibility for GHG emissions, here regard to jurisdiction. Neither the UNFCC[12] nor Kyoto[13] regulated explicitly what may be called the states "spheres of emissions quotas". The general rule in international law is that states are "responsible for activities within their jurisdiction and control". This is expressed in Rio Declaration, principle 2 as well as in the preamble to the UNFCCC.

Development of a commercial CO2 transportation infrastructure will require producers of CO2 undertaking a payment commitment (e.g. a take or pay or minimum volume contract) sufficient to make a financial recovery of the investment at a reasonable rate of

[11] European Commission: Developing a European CO2 transport infrastructure (2011).
[12] The United Nations Framework Convention on Climate Change (UNFCCC or FCCC) is an international environmental treaty produced at the United Nations Conference on Environment and Development (UNCED), informally known as the Earth Summit, held in Rio de Janeiro from June 3 to 14, 1992.
[13] The Kyoto Protocol is an international agreement linked to the United Nations Framework Convention on Climate Change. The Kyoto Protocol was adopted in Kyoto, Japan, on 11 December 1997 and entered into force on 16 February 2005.

return. If such a payment obligation is secured, the organisation of the ownership and operation could follow the model of an upstream petroleum or gas pipeline with the only difference that governments need to cover the political risks in the case of CO2 transport and need to ensure that the whole CCS chain is economically viable. A joint venture of owners, with or without state participation, could be formed, and an independent operator could be appointed.

Enhanced oil recovery (EOR) with CO2 can be an enabler for the development of CCS. The revenues from the additional oil produced can help finance the (early) CO2 transport infrastructure, with added benefits of additional tax revenues, stability of security of energy supply and greater competitiveness of the EU Member States. The window of opportunity for the application of CO2-EOR in the major oil fields in the North Sea requires both a rapid and early ramp-up of capture efforts and a concentration of the supply of captured CO2 towards the oil fields. Early in the development of CCS, an organised, cross-border effort is needed to fully exploit the opportunities of CO2-EOR. It is recommended to look into the feasibility of aligning CCS development and CO2-EOR options. A dedicated tax and revenue and burden sharing system could be developed, to render investments in CO2-EOR projects in the North Sea attractive. Such measures could result in kick-starting both CCS and CO2-EOR at the same time.[14]

6 Conclusions

Harmonisation of CO2 transport and storage access regimes is essential for project developers and investors considering a CCS project that requires the cross-border movement of CO2. Likewise, with the uptake of CCS, harmonized rules for CO2 infrastructure charging will create the required level playing field between different CO2 emitting industries.

The present situation of especially cross-border CCS and transportation is unclear. Neither general international law concerning principles of jurisdiction no rules on the international climate regime are fully adequate and suited as a basis for sharing responsibility between party states to a cross-border CCS chain. This problem should be considered thoroughly because of the huge potential for cross-border CCS in the future.

However, the jurisdiction criteria does not provide clear answers to all questions that are raised, especially in situations where leaks occur from pipelines or vessels. This may lead both to under-reporting of emissions and conflicts between interested parties. A more fundamental question is how the jurisdiction criteria will work as incentive for the development of trans boundary CO2 capture and storage. At the outset, it means that the state where capture takes place will have the full benefit of CCS, as its emissions are reduced. Conversely, states that have jurisdiction for transport and storage also have risk having emissions from leaks counted towards their assigned amount. In this situation,

[14] European Commission: Developing a European CO2 transport infrastructure (2011).

the transporting and storage state must and probably will seek adequate compensation from the capture state for taking the risk burden.[15]

Another problem appears if states with no emissions reduction obligations in a post-Kyoto regime take a role in cross-border CO2 chains.

Costs and financing aspects of the development of a large-scale CO2 transport network need to be resolved before larger scale CCS will be able to develop. Investments in large-scale CO2 transport infrastructure and strong tax incentives (e.g. EU-ETS) need overall European public planning, as investments are not likely to be carried out by industrial partners alone. Also, cost differences may arise between earlier and later CCS projects, so mechanisms need to be in place to prevent undue cost escalation. To prevent costs for redesigning and rebuilding to connect non-compatible infrastructure among countries, it is important to harmonise the technical solutions used across the EU as early as possible.

Renewable Portfolio Standard (RPS) in Korea: How to Make It Work

Sangmin Shim[1]

[1]JSD Candidate,
Stanford Law School, Stanford, CA 94305, U.S.A.
Republic of Korea

Email: smshim@stanford.edu

Abstract:

This paper explores the scope and implications of the Renewable Portfolio Standard (RPS) in Korea, and considers the ways to make the best of the regulations' potential. Combined with the trading of renewable energy certificates (RECs) issued to renewable generators, the RPS can work as an effective tool to expand renewable generation at affordable costs. After observing what has happened with the RPS in Korea so far, this paper raises the possibility that the RPS's potential will not materialize due to the design flaws in the regulation. Too ambitious target-setting, the RECs market prone to manipulation by market participants, and the multipliers' distortionary effect are pointed out as hampering the regulation's operation. Certain changes in the RPS regulation are therefore warranted, to make sure the policy objectives of securing sizeable renewable generation may be obtained at reasonable costs without too much market distortion. Employing the design analysis of the RPS regulation, as well as the statutory analysis of the relevant legal provisions, this paper proposes several changes in the RPS regulation, such as readjustment of target-setting and their strict enforcement, expansion of the buyer base in the RECs market, and reassessment of multipliers which altogether will help better serve the policy objective of expanding renewable generation at affordable costs.

Keywords:

Renewable Portfolio Standards (RPS), Korea, Renewables, Electricity, Renewable Energy Certificates (RECs)

1 Introduction

Tapping into non-fossil fuel sources for electricity generation is a requisite for any nation that is serious about implementing climate policy. Korea is not much different, considering that it has announced the target of voluntarily reducing its business-as-usual (BAU) greenhouse gas emissions by 30 percent by 2020 (Presidential Committee on Green Growth, 2012). Among the various options for Korea to successfully meet its emission reduction target will be included increasing use of renewables in power generation, as is outlined in the 5th Basic Plan for Long-Term Electricity Supply and Demand which is a governmental plan on power supply and demand detailing the policy

measures for the next 15 years (Ministry of Knowledge Economy and Korea Power Exchange, 2010).

An important question in this context is which policy tools to use in order to help increase the renewables' share in the national generation, and Korea's recent change in its choice of tools is worth a closer look. The Korean government employed feed-in tariffs (FITs) from 2002 until 2011, by which renewable electricity generators were subsidized for the differentials of the generation costs and the standard prices set by the government for each renewable source (Lee and Yoon, 2010). From this year, however, Korea has begun a set of new regulations in this field, Renewable Portfolio Standard (RPS), due to the concern that the FITs were incurring too heavy financial burden on the government without expanding renewables in a timely manner (Moon et al., 2011). Applied to the generation companies with the capacity of 500 megawatts (MW) and over, the RPS requires a certain portion of their electricity generation to come from renewable sources. Compared with the FITs, the RPS is deemed as a better tool to ensure quantity in the expansion of renewable generation, with the incurred cost to be optimized through the market competition among renewable generation companies (Lee and Park, 2008).

An observation of what took place with the RPS in Korea raises concerns, however, that the RPS's potential benefits may not materialize, mostly due to the design flaws in the regulation. As this paper duly explains later, too ambitious target-setting makes it difficult for the electricity generation companies to meet the RPS target within the suggested time frame, so that they rather take minimizing the adverse consequences of non-compliance as their second-best option, resulting in the non-accomplishment of the target. Restrictions on the participation in, as well as the trading within, the renewable energy certificates (RECs) market allow possibilities of strategic behaviour by the electricity generation companies under the RPS, hampering the smooth functioning of the market and adding difficulties to the expansion in renewable generation in the short term. In addition, multipliers, which were designed to favour certain technologies against the others to increase their market presence, drive the obligated generation companies toward big-scale renewable generation projects that take longer time to build with greater environmental impact, resulting in delays of providing the renewable electricity that will translate into non-compliance. Certain changes in the RPS regulation are therefore warranted, to make sure the policy objectives of securing sizeable renewable generation may be obtained at reasonable costs without too much market distortion.

Before answering the question of how to make the RPS in Korea work, this paper begins with the discussion on the policy tools intended to help renewables expansion, namely FITs and RPS, and compares their advantages and disadvantages. It also highlights the government's concerns on the financial burden as well as on the balance of trade payments, two unique constraints that overshadow any of Korea's policy discussions on renewables. Then this paper moves on to describing the particulars of the RPS regulation in Korea, before providing an analytical explanation of the current situation to shed light on some elements in the RPS that potentially reduce benefits for both electricity generation companies and renewable generators. This paper proposes several changes in the RPS regulation governing target-setting, market participation and multipliers, and concludes that such changes will better serve the policy purpose of increasing renewable generation at affordable costs.

2 Choice of Policy Tools on Renewables: FITs or RPS?

The objective of expanding renewables in the national generation portfolio has been tried and implemented in many other jurisdictions, and the two of the policy tools that most governments opted to employ are FITs and RPS. While they have their own advantages and disadvantages, their essential differences lie in how to bear the cost of burdens and which kind of certainty are provided for renewable generators. The following descriptions provide information on the advantages and disadvantages of each policy tool, bringing insight to the rationale behind adopting one policy tool against the other, which is exactly the Korean case.

2.1 FITs: Advantages and Disadvantages

FITs are in essence the subsidy paid by the government to renewable generators to promote their market presence, helping them with a guaranteed income even when the electricity market price goes below their power production costs (Murray, 2009). Typically this policy tool works by the government or by utilities companies paying out the differentials between the market price of electricity and the standard prices duly reflecting the generation costs of renewables, thereby giving renewable generators price guarantee and a reliable source of revenue for the duration of the FIT contracts (Davies, 2011). In fact, since the government may apply higher standard prices for renewable sources of which the generation costs are higher than those of other renewables, it can provide technology forcing for those renewable sources with cost disadvantages, making for a more balanced renewable generation portfolio (Lee and Yoon, 2010).

The biggest disadvantage of FITs is that the cost burdens on the government or utilities can become significantly large if the speed of renewable expansion becomes faster than the government's expectation, resulting in the mid- to long-term constraints in the governmental budget situation (Lee and Yoon, 2010; Presidential Council on Future and Vision, 2009). In addition, setting the standard prices right for various types of renewable is important but not always easy to do, given the market uncertainty and the information asymmetry concerning the generation costs (Lee and Park, 2008).

Considering that FITs may incur high costs for implementation, this policy tool is likely to be more suitable in countries with advanced economy – meaning deeper pockets – and with high environmental awareness on energy production. In fact, of 48 countries implementing FITs, many are located in Europe, such as Denmark, Germany and Spain (Davies, 2011).

2.2 RPS: Advantages and Disadvantages

RPS works for the same policy objective of renewable expansion as sought by FITs but with one important distinction: The financial burden for ensuring renewable expansion lies with generation companies, not the government (Lee and Park, 2008). In essence, RPS requires that generation companies provide a certain portion of their power generation from renewables, either by running renewable facilities themselves or by purchasing renewable electricity from other renewable providers. Often it is combined with some market mechanisms, named "renewable energy certificates (RECs)", allowing generation companies to purchase those renewable credits to fulfil the RPS requirement (Davies, 2011).

The advantages of RPS include the fact that it gives clear targets for electricity generation companies to accomplish, providing certainty in relation to the renewable expansion (Lee and Park, 2008). In addition, the implementation costs will likely be lower, by allowing flexibility with the trading of RECs in the market (Davies, 2011; EPA, 2009). It is noteworthy, however, that this point assumes the existence of a well-functioning certificate market, which is not always the case as the discussion in section 4 suggests. Lastly, the government's concern on the budget situation will likely be appeased, as the generation companies under the RPS bear responsibility for ensuring renewable expansion, assuming financial burdens as well, while they attempt to minimize their costs by turning to most efficient renewable generators (Lee and Park, 2008; Lee and Yoon, 2010).

Meanwhile, the lack of a price guarantee for renewable generators, as well as the possibility for generation companies under the RPS to resort to renewables with the lowest production costs, will tend to block the advances of certain renewables with great potential but with little price competitiveness (Lee and Park, 2008). Such disadvantages may be overcome with the use of multipliers for different renewable sources and with the establishment of set-asides for certain renewables, as will be discussed later, but their success will depend upon sound and well-functioning regulatory schemes.

As of 2010, 44 nations worldwide implement RPS regulations, including the United States, the United Kingdom, Australia, Italy, Sweden and Japan (Lee, 2010).

2.3 Insight on Korea's Renewable Policy

It is worth noting that Korea is still interested in growing its economy through export, given its small land size and the limited natural resource reserves. This stance is epitomized in Korea's 'low carbon, green growth' strategy, which is a name for the national climate policy but with more emphasis on exportation of Korean green technologies, nuclear included (Ministry of Government Legislation, 2010). The question of trade balance will therefore become a sensitive issue in governmental policies, including those on renewables, if such supportive policy ends up significantly increasing importation of equipment from foreign countries. Given the weak industrial base in Korean renewables (Lee and Park, 2008), this is unfortunately the case here.

In addition, most of the electricity generation sector is under the government's hand, with the government-owned generation subsidiaries having provided 435 terawatts per hour (TWh) in 2010, more than 90 percent of the electricity (KEPCO, 2011). It is also very difficult to increase electricity rates to recover increased costs for generation, due to the concern on price stability and the Korean industries' international competitiveness, evidenced by the fact that from 1982 to 2010 the electricity rates rose 19.6 percent while the consumer price index rose 208 percent (Chang, 2011). Under these circumstances the size of the payment made to support renewable generation duly becomes a concern for the Korean government, even though its policy goals is to effectively increase the renewable expansion in a timely manner.

Seen from this perspective, it is not surprising that the Korean government dumped the FITs and switched to the RPS, as a cost-saving measure, even with the list of literature suggesting FITs' superiority over RPS in terms of renewable expansion (Lee and Park, 2008; Davies, 2011). That being said, it should be all right if the Korean government went ahead with the RPS with the right set of regulations governing the related market

and the details, as the disadvantages of the RPS could be mitigated by the application of other tools, such as multipliers and set-asides. The key question to ask is, then, whether such regulation duly takes into account the current market situation in Korea or it does not foresee distortions coming from the flawed regulatory design.

3 RPS Regulation in Korea

This paper begins with touching on the transition from FITs to RPS, highlighting the FITs' strengths and weaknesses that brought the introduction of the RPS. Then it moves on to explaining the details of the RPS, discussing the renewable generation requirements for major generation companies and the RECs, which represent the electricity generated from renewables that are tradable in the market under certain conditions. These discussions help laying the groundwork for analysing the situation being unfolded under the current regulation.

3.1 Transition from FITs to RPS

First introduced in 2002 to promote the expansion of renewables (International Energy Agency, 2004), the FITs were a supportive scheme by which the government set the preferential standard prices for each renewable generation type, and pays renewable generators the differentials between those standard prices and the market prices (Yoon, 2008). Guaranteed for either 15 or 20 years from the time each facility became operative, the FITs gave renewable generators reasonably long-term price stability as well as a secure revenue flow. On the other hand, they were not the most effective tool in guaranteeing these renewable sources a fixed portion of market presence, essentially providing price certainty but not quantity certainty, as consistent with the general features of FITs (Lee and Park, 2008).

As for the risk that the payments to renewable generation would grow too fast, the government provided safety valve measures to keep that from happening. For instance, the standard prices would decrease annually to reduce incentives for excessive expansion (Lee and Park, 2008). Still, it did not prevent the glut of photovoltaic generation, with a view to taking advantage of the generous FITs for solar photovoltaic which was up to six times higher than the wholesale market price (Yoon, 2008). The solar photovoltaic capacity thus increased exponentially, from just over 200 kilowatts (kW) in 2004 to 347 megawatts (MW) in 2009 (Korea New and Renewable Energy Center, 2010). The government spending to fund FITs also skyrocketed, from 7.8 billion Korean won in 2005 to 262.6 billion Korean won in 2009 (Electric Power Public Tasks Evaluation and Planning Center, 2012), with more than 90 percent of the FIT budget directed to solar photovoltaic generation only (Kwon, 2009; Ministry of Knowledge Economy and Korea Energy Management Corporation, 2011). It did not help that the ratio of the domestic parts used in solar photovoltaic generation facilities was around 50 to 60 percent (Ahn and Chung, 2010), since more installation of solar panels would translate into more imported parts, worsening the balance of trade payments. Therefore, capacity caps were introduced in 2009 to apply to solar photovoltaic, wind power and fuel cell, paying out the FITs until the total capacity cap would be reached. The capacity cap for each of the power sources was 500 MW for solar photovoltaic, 1,000 MW for wind power, and 50 MW for fuel cell. These capacity caps would also break down to annual allocations for solar photovoltaic and fuel cell.

In the case of solar photovoltaic, annual allocations were 50 MW in 2009, 70 MW in 2010, and 80 MW in 2011, respectively. The solar photovoltaic electricity in excess of the annually allocated volume would not be subsidized by FITs but should be sold at market price, which put solar power generators at a great disadvantage.

The government eventually succeeded in limiting the costs of running FITs, but lost the program's effectiveness in expanding renewable power generation, as evidenced by the fact that the net solar photovoltaic facility installation dropped from in 257 MW in 2008 to mere 72 MW in 2009 (Choi, 2010). A change of policy tools by the government would have been inevitable, which would hopefully help regain a balance between the expansion of renewable generation and the minimization of the cost burden. Given the government's hanging concern on the cost minimization, however, the limits to how far this pursuit of renewable expansion would go were self-evident.

Under the newly introduced RPS regulation, the responsibility of providing renewable generation is transferred from the government to major generation companies with the generation capacity of 500 MW or bigger. Considering that the government-owned generation companies possess more than 80 percent of the national generation capacity (Korea Electric Power Corporation, 2011), however, the government still bears ultimate responsibility to ensure the expansion of renewable generation. Meanwhile, other considerations such as trade of balance and cost minimization should continue to play a role in guiding the government's course of action in this regard.

3.2 Details of the RPS

The following discussion of the RPS regulation is based on the relevant provisions of the presidential decree on the RPS[1] and the ministerial decree on the RPS.[2] Unless indicated otherwise, the articles appearing in the text refer to those in those ministerial decrees.

3.2.1 Renewable Generation Requirements

With the introduction of the RPS, generation companies with the generation capacity of 500 MW are obligated to produce a certain portion of their electricity generation from renewables (Presidential Decree, Article 18-3). Not all renewable sources are included for such generation requirements, however, and what are listed as acceptable by the relevant law[3] are wind, solar, tidal power, hydropower, biogas, landfill gas, biomass, fuel cell, integrated gasification combined cycle (IGCC) and waste. The national RPS targets start from 2 percent of electricity generation in 2012, which increases by 0.5 percent point until 2016, and then increasing by 1 percent point to 2022, reaching 10 percent of the national generation. Given that 1.24 percent of the national generation came from renewables in 2010, hydropower included (Korea New and Renewable Energy Center, 2011), achieving an eight-fold increase of renewable generation in over 12 years can easily become a challenge. With the Korean government unwilling to take on financial consequences of steep expansion of renewable generation under the FIT

[1] Presidential Decree on the Law on the Development, Utilization and Promotion of New and Renewable Energy, Presidential Decree No. 23640, revised and entered into force on February 28, 2012 [hereinafter Presidential Decree].
[2] Ministerial Decree on the Maintenance and Operation of the RPS, Ministry of Knowledge Economy Decree No. 2011-290, revised and entered into force on December 27, 2011 [hereinafter Ministerial Decree].
[3] Law on the Development, Utilization and Promotion of New and Renewable Energy, Law No. 10445, revised and entered into force on January 1, 2012 [hereinafter Law].

scheme in the past, one may question if such aspirational targets with the RPS regulation are realistic indeed.

A scheme of solar power generation requirements, called 'set-asides', is also put in place (Law, Article 12-5.2), which will keep increasing until 2016, to promote the domestic photovoltaic industry. These set-asides are included in the overall renewable generation targets. Table 1 shows the overall renewable generation targets as well as photovoltaic set-asides by year.

Table 1. Renewable Generation Targets and Solar Set-asides by Year

(Source: Ministry of Knowledge and Economy, 2012)

Year		2012	2013	2014	2015	2016	2017	2018	2019	2020	2021	2022
Overall Targets (%)		2.0	2.5	3.0	3.5	4.0	5.0	6.0	7.0	8.0	9.0	10.0
Solar Set-asides	Generation (GWh)	276	591	907	1235	1577	1577	1577	1577	1577	1577	1577
	Capacity (MW)	220	450	690	1040	1200	1200	1200	1200	1200	1200	1200

13 generation companies are currently under the renewable generation requirements, combining eight government-affiliated companies and five private ones. Their required renewable generation assignments vary in size, to take into account other factors such as their current generation portfolio. These companies are obligated to meet their assigned renewable generation targets, although they can postpone implementing up to 20 percent of their annual targets to the following year (Ministerial Decree, Article 18-3.5). To allow for more flexibility in the implementation process, the postponement of meeting their targets, which is called borrowing, is up to 30 percent of their annual targets during 2012-2014. The obligated generation companies are expected to meet their requirements either through constructing their own renewable generation facilities and producing electricity from them, or by purchasing RECs from other renewable generators (Law, Article 12-5.5).

In case the obligated generation companies fail to fulfil the renewable generation requirements, they should pay fines for up to 150 percent of the annualized average price of the RECs multiplied by their unfulfilled amount (Law, Article 12-6.1). These fines cannot be passed on to the retail electricity prices, while the recovery of implementation costs related to RPS regulations, such as investment of renewable facilities and purchase of RECs, is possible through electricity rate increases in the future (Presidential Decree, Article 18-11). Given that the retail rate increases have been difficult in the past, however, the cost recovery may not proceed as the obligated generation companies hope for, which will lead them scrambling for the least costly renewable generation available, transaction costs included.

3.2.2 Renewable Energy Certificates (RECs)

RECs are an instrument verifying that generation has been made from renewable facilities, certified and issued by the New and Renewable Energy Center, a government-affiliated organization. One REC represents the value of 1 megawatt per hour (MWh) of renewable generation.

To promote certain renewable power sources with strategic importance to the national economy, the multiplier scheme is also put in place. In essence, different multipliers are applied to different renewable sources when calculating the final value of renewable generation as RECs. Such multipliers vary from 0.25 in the case of IGCC generation to 2.0 in the case of tidal power with new embankment construction and fuel cell generation. For instance, if a renewable generator produced 1MWh of electricity using tidal power with new embankment construction, the final value of the renewable generation comes out to be 2 RECs (1MWh × 2.0 multiplier = 2 RECs). Table 2 lists the multipliers by different power source and technology.

Table 2. Multipliers by Renewable Source and Technology
(Source: Ministry of Knowledge Economy, 2012)

<table>
<tr><th>Grouping</th><th>Multiplier</th><th colspan="3">Source Type and Technology</th></tr>
<tr><td></td><td></td><td>Installation</td><td>Land Type</td><td>Capacity</td></tr>
<tr><td rowspan="4">Solar</td><td>0.7</td><td rowspan="3">New</td><td colspan="2">Rice Paddy, Dry Field, Orchard, Pasture, Forest</td></tr>
<tr><td>1.0</td><td rowspan="2">Others</td><td>Over 30kW</td></tr>
<tr><td>1.2</td><td>Under 30kW</td></tr>
<tr><td>1.5</td><td colspan="3">Over Existing Buildings and Facilities</td></tr>
<tr><td rowspan="5">Other Renewables</td><td>0.25</td><td colspan="3">IGCC</td></tr>
<tr><td>0.5</td><td colspan="3">Waste, Landfill Gas</td></tr>

<tr><td>1.5</td><td colspan="3">Small-scale Offshore Wind Farms</td></tr>
<tr><td>2.0</td><td colspan="3">Large-scale Offshore Wind Farms, Tidal Power (new embankment construction), Fuel Cell</td></tr>
</table>

RECs are valid for three years after the date of issuance (Law, Article 12-7.4), for which time they are tradable in the spot market run by the New and Renewable Energy Center once a month, although the buyers of such RECs are limited to the 13 obligated generation companies. The RECs that those 13 companies generate using their own renewable facilities are excluded from trading, but they count towards meeting their renewable generation requirements. Under a degree related to the RECs,[4] trading of RECs is one-time only (Center Decree, Article 34), meaning that no secondary market will be allowed. To reflect their generation cost differentials, solar-based RECs are traded separately from other renewable-based RECs.

It is also possible for the obligated generation companies to enter into long-term contracts with renewable generators and earn RECs as a result (Center Decree, Article 30.1). In the case of solar-based RECs, the New and Renewable Energy Center may

[4] Center Decree on the Issuance of RECs and the Operation of the REC Market, New and Renewable Center Decree No.2012-11, revised and entered into force on May 22, 2012 [hereinafter Center Decree].

help find those renewable generators, by running an auction twice a year based on the renewable generators' bid price to meet the obligated generation companies' demand of RECs. Another special provision for solar photovoltaic generation is that generation companies with the generation capacity of 5 gigawatts (GW) should purchase at least 50 percent of the solar-based RECs they need to meet the set-asides requirement (Ministerial Decree, Article 10.1). Six government-owned generation companies are under such a requirement.

4 Assessment of the RPS: Doomed?

Only six months have passed since the RPS was introduced, and therefore it will be too early to tell whether the RPS is going forward successfully or doomed to failure. There are ominous signs on the horizon, however, that the regulation in its current form is not conducive to achieving the policy objective, which is to expand renewable generation at affordable cost. This section explains what has been going wrong with the RPS, and critiques some elements in the regulations that hamper the effective functioning of the RPS and the REC transactions.

4.1 Too Ambitious Target-Setting

In general the RPS targets would better be set high to encourage renewable generators and to reduce uncertainty for their businesses (Lee and Park, 2008). Considering that the renewable generation in 2010 was a mere 1.24 percent of the national total generation, increasing the renewables' share to 10 percent in over twelve years will be a tall order in any case. If the generation outlook for 2022, 598.9 TWh (Ministry of Knowledge Economy and Korea Power Exchange, 2010), serves as a reference point, the required generation from renewables should reach at 59.8 TWh, almost a ten-fold increase from the renewable generation of 5.88 TWh in 2010. An added concern is that Korea does not abound in renewable generation potential, maxing at 815.7 TWh with all technologically available sources (Ministry of Knowledge Economy and Korea Energy Management Corporation, 2011), less than twice the electricity generation in 2010 at 474.6 TWh (Korea Electric Power Company, 2011). If the economic factor, i.e., cost factor, is taken into account, the economically available renewable generation sources would shrink further.

Under such unfavourable circumstances, mostly aspirational targets would end up short of achieving the stated goals. The obligated generation companies already opine in public about failing to meet the targets and about being subject to fines as a result, notwithstanding their best efforts to expand their own renewable generation and to purchase RECs from the market, as there are simply not going to be enough RECs available (Yoo, 2012). Furthermore, this failure to meet the RPS targets may lead to the obligated generation companies' strategic behaviour to guard against the worst consequences for their non-compliance as the second-best option, which will be discussed in the next subsection.

In sum, with all its good intention, this ambitious target-setting opens a door to the 'salience distortion', 'the facial representation of an aggressive goal that, in fact, is not aggressive at all' (Davies, 2011).

4.2 REC Market Prone to Manipulation

The REC markets are composed of two elements, which are for solar photovoltaic only and for the other renewable power sources. In the case of other renewable REC spot markets, the bidding processes have been smooth in the past four months, and the market prices for RECs duly represent the fair value of the renewable generation. However, the solar photovoltaic REC market is showing signs of turbulence, as shown in the last bidding process for solar power contracts and spots where the obligated generation companies limited their REC demand to such a small number that drove down the price for the solar photovoltaic RECs by 30 percent (Jeong 2012). Table 3 illustrates the details of solar and non-solar REC transactions in the past four months.

Table 3. Solar and Non-solar REC Transactions in the Spot Market by Month (2012)
(Source: Jeong, 2012; Kim, 2012)

	Mon/Year	Feb/2012	Mar/2012	Apr/2012	May/2012
Solar RECs	Quantity (RECs)	18	44	553	4
	Price (Korean won)	229,400	220,000	219,862	161,000
Non-Solar RECs	Quantity (RECS)	1,031	-	1,254	4,215
	Price (Korean Won)	42,400	-	48,193	52,251

As the solar photovoltaic market is currently suffering from oversupply of solar panels (Han, 2012), the market for providing solar power electricity has become a buyer's market. Depending upon the buyers' strategic moves the price could drop further, benefitting the obligated generation companies at the expense of solar photovoltaic generators. Considering that the obligated generation companies could put off complying with their annual targets for up to 30 percent in the first three years of the RPS regulation, they may find it beneficial to purposefully hoard their renewable power demand in early years, driving down the REC prices for solar photovoltaic and profit from the purchase of cheap RECs of which the value is suppressed due to market manipulation. Since the prices of RECs are also relevant in calculating fines for non-compliance, these obligated generation companies have further incentives to keep the REC prices down. These suppressed REC prices will act to drive many solar photovoltaic generators out of the market, resulting in the devastation of the supply base if this phenomenon continues for a long time, which may make it difficult for the solar set-asides to be met and hurt the generation companies as well.

It would be too early to conclude the obligated generation companies' moves as manipulative, as they may indeed have had other reasons to demand less RECs in that specific month. The transaction records for solar RECs suggest, however, that the possibility of market manipulation due to the market participants' strategic behaviour is sufficiently real, and may even increase in extent given the market dominance the obligated generation companies currently enjoy.

4.3 Distortion through Multipliers

Multipliers are intended to provide support for renewable projects that are economically disadvantaged to build and operate, by increasing the number of RECs that are issued

from those renewable generation projects (Ministry of Knowledge Economy, 2012). However, the differentials of multipliers being applied to various renewables appear to favour big-scale facilities that take long to construct, whereas their overall environmental values are somewhat questioned. For instance, the highest value of 2.0 is given to such large-scale projects as off-shore wind farms and tidal generation with newly constructed embankment. Drawn by its high multipliers and low construction costs, some obligated generation companies rushed towards tidal generation (Lee, 2012), expecting an early take-off. Instead, because of the anticipated significant impact on the adjacent environment, such big projects are being held up by lawsuits and by local residents' protests (Thacker, 2011), which will not help serving the policy goal of securing renewable generation expansion in a timely manner, the very reason that the government chose to introduce the RPS instead of the FITs.

5 Suggestion for a Better RPS

While the policy goal of expanding renewable generation is in itself admirable, the means of implementing the RPS regulation are under serious doubt, raising concerns that the regulation may not show its full potential due to the combination of several design flaws. With the irregularities shown six months into the implementation, the RPS regulation warrants careful reconsideration of some of the policy elements to make the whole scheme work better. The below are some suggestions to address those irregularities, with a view to guaranteeing continuous success of the RPS regulations as a policy tool to achieve renewable generation expansion at affordable costs.

5.1 Adjustment of Targets with Strict Enforcement

Even though the government decided to switch from the FITs to the RPS to alleviate its concern on the financial burden of supporting renewables, the stated policy goal of renewable expansion ought to be sought to the utmost extent possible. Under the circumstances where the obligated generation companies openly discuss possibilities of not meeting the RPS targets and worry about paying fines as a consequence, however, the ambitious target-setting through 2022 will not make sense, as it is simply counterfactual. Renewable targets that are based on realistic assessment of renewable generation potential, combined with regulatory certainty in ensuring the attainment of policy objectives, will be a better fit in the new regulatory environment. This paper therefore suggests scaling down on the yearly renewable targets by 20 percent, with the year 2022 target reset at 8 percent. This number is more in line with the 5th Basic Plan for Long-term Electricity Supply and Demand, which projects generation from renewables in 2024 at 7.9 percent of the total national generation (Ministry of Knowledge Economy and Korea Power Exchange, 2010). While the end result of such adjusted targets may well be short of the originally stated goal for fast renewable expansion, here the real choice should rather be made for modest and realistic targets, over aspirational targets that will surely not be met.

In combination with the readjustment of renewable targets, measures to solidify them will also need to be taken, to minimize the room for the obligated generation companies to attempt non-compliance with the regulation. One of the measures conceivable is the abolition of the borrowing provision, at least from 2015, the end of the first three years since the introduction of the RPS. As the relevant provision may provide the obligated

generation companies with excuses for not being serious in meeting their annual targets, rather than helping them with flexibility in compliance, it may be removed once the unrealistic targets are readjusted.

5.2 Expanding Buyer Base in the RECs Market

Due to the ambitious renewable target-setting, in theory the RECs market should be characterized as a seller's market, implying the expected shortage of supply in RECs and the upward tendency of such certificates' prices in the market over time. However, as there are only 13 generation companies that can act as purchasers of RECs, the market power that they can wield to press down on the REC prices will be significant. The recent records on the solar photovoltaic REC prices gives credence to the concern that the RPS's policy objective may be frustrated without enough demand for RECs. Without rigorous monitoring of the market behaviour, it is even possible that obligated generation companies will behave strategically to put downward pressure on the REC prices.

As an alternative, it would be advisable to expand the buyer base to include other non-utilities with expertise in providing renewable generation in the best economic fashion, such as energy brokers and other intermediaries. It essentially means allowing the introduction of a secondary market for RECs, such as is possible in the United States (Chumak, 2008), by letting purchasers and sellers freely decide on the price and quantity of RECs being traded. For this possibility to become materialize, certain provisions restricting the trading of RECs acquired at the market, such as limiting the number of times the RECs can be traded, would better be removed. In addition, the participation of the government in the RECs market may help stabilize the prices of RECs, by acting as a buyer of RECs when the demand of RECs is too weak in a certain auctioning day and also by acting as a provider of RECs when the demand of RECs is far stronger than usual. The government is reported to have shown interest in participating in the RECs market as a RECs supplier (Energy Korea, 2012), but the government could also help the RECs market mature by acting as a buyer of RECs, for use when the market destabilizes in the future.

5.3 Reassessment of Multipliers

As mentioned earlier, the manner in which multipliers were set for each renewable generation method had the effect of favouring large-scale renewable projects such as tidal generation and offshore wind farms, weakening the potential of some promising renewable technologies. Even if the RPS regulations still has as a policy objective promoting renewable industries, and while one of the rationales behind the multipliers is providing incentives for some renewable technologies that are not yet the most economical and are difficult to tap, there must be a balance between environmental and industrial policy perspectives, not favouring technologies with potentially destructive effects on the neighboring environment. At least the multiplier of 2.0 given to large-scale offshore wind farms, tidal power generation with new construction of embankments, should be reduced to 1.5, the same value given to smaller-scale offshore wind farms. This type of readjustments will also help the obligated generation companies look for other renewable options with more potential for timely provision and less social friction.

The government is also not insistent on sticking with the current values of multipliers, as these multipliers are subject to periodic reviews every three years (Ministerial Decree, Article 7; Ministry of Knowledge Economy, 2012). When such periodic reviews are made, a more emphasis should be placed on the environmental integrity of renewable generation methods, rather than on the promotion of certain renewable generation technologies for industrial policy purposes.

6 Conclusion

In addition to energy independence, expanding renewable generation has other positive effects, including less greenhouse gas emissions by relying less on fossil fuels, and environmental benefits coming from less-polluting generation technologies. The search for a cost-effective means to achieve such a policy objective brought about the introduction of the RPS regulation in Korea, but the regulatory scheme in its present form is potentially frustrating the stated policy goal due to the flawed regulatory design. This paper is an effort to redress such defect by reassessing and redesigning some of the elements in the RPS regulation, so that the RPS's main objective of expanding renewable generation at affordable costs can be accomplished. If the RPS's incentive structure is rearranged along the lines of this paper's suggestions, Korea will hopefully see a steady growth of renewable generation in the next decade, promising herself to become one of the leading nations in terms of renewable generation as well as the policy designs related to the RPS.

The Impact of Interventions on Projects: a Case Study of Public Interest Litigation

Ellen Lau[1]

[1]Division of Building Science & Technolgy,
City University of Hong Kong,
HKSAR, China

Email: bsellenl@cityu.edu.hk

Abstract:
Successful project management is traditionally based on the eternal triangular relationship of cost, time and quality. The control mechanisms and management techniques are therefore based on these criteria. Legal interventions are not normally anticipated in disrupting the planning or the progress of projects. Now that there are new expectations from global development, climate change and environmental impact, issues of public interest has become one form of project risks that their interventions can be so diversified that they require different management techniques. Interventions hereby refer to intervening events arising from the law of public interest in disrupting project planning or project progress. Public interest litigation and the principles are discussed. A case of judicial review of an infrastructure project is selected for detail analyses to reveal the root causes for legal actions and the associated impacts on time and cost in disrupting the projects. The findings are intended to provide a scenario of the impacts of legal interventions on the projects. It is expected that the case would provide implications of the public law to inform how to reduce the impact of the intervening event.

Keywords:
case study, interventions, judicial review, public interest litigation

1 Introduction

Judicial review (JR) has recently been popular not only for applying to the usual human rights and immigration matters, but also to environmental law and policy matters affecting projects. It is nowadays used as a 'legal step' by the stakeholder to acquire their civic right in the legal administrative system on issues of public interest. Since there are new expectations in the society coming from global development, climate change and environmental impact, construction projects may be disrupted by intervening events relating to public interest and bring time and cost consequences. Presently there is no one form of management technique appropriate for handling such project interventions. An infrastructure project, which has been undergone court proceedings for application and for appeal, with ample public interest and attention, is examined to inform how to reduce or to accommodate the impact of the interventions.

 ISBN: 978-1-84219-840-7 .

2 Public Interest Litigation

Public interest litigation (PIL) means to protect a general interest that is larger than that of individual case interest. It is common that the applicant would seek legal aid to pursue the social and economic rights of a largely urban and consumer society such as for the economic well-being of an emerging middle class (Fu & Cullen, 2011). There are incentives for public interest litigation as the judicial process is well structured with a degree of predictability, transparency and publicity; and for this reason, there is a higher expectation of fair play in the judicial process in comparing to other political and administrative process (Fu & Cullen, 2011). Thus, public interest in law concerns its bearing in justice whereas public interest litigation tends to be a process for debating social justice.

Judicial review is a form of court proceeding in which a judge reviews the lawfulness of a decision or action made by a public body. It is based on an allegation that the public body has taken an unlawful decision or action while there is no adequate alternative remedy. The key issue of a judicial review is whether the correct legal basis has been used in reaching a decision, and not about whether the decision is 'right' or 'correct'. [1] Public law project research is now regarded as an important part in government policy formation and legal reform.

In the constitutional law of the UK, JR is a control by courts over certain decisions taken by administrative and other decision-making bodies of the government, usually the parliament (Olley, 2003). The applied rules is that derived from the case Associated Provincial Picture Houses v. Wed-nesbury Corporation [1948] 1 KB 223. The 'Wednesbury' principle derived from the case is that the courts may interfere where the decision that has been taken is one that no reasonable body could have reached *(*Stewart & Burgess, 2001). The basis for making decision in a JR can be referred as:

'one can conveniently classify under three heads the grounds upon which administrative action is subject to control by judicial review. The first could I would call illegality, the second irrationality, and the third procedural impropriety'.[2]

The question on JR is raised because it has been queried that the courts are applying the intent of the legislature. When case law is applied, the court decision in a JR case would become a legal reference for future case. With JR being a central principle of the administrative law, a JR case then becomes a foundation for legislation. The difference can then be seen between the civic system and the common law system as to how "law" is made and how policy is established.

The *ultra vires* principle is based on the assumption that judicial review is legitimated on the ground that the courts are applying the intent of the legislature. This is vital to the developed law of JR. In the English law, JR is about the doctrine of ultra vires, the

[1] The Public Law Project Information leaflet 2, 2006)
http://www.publiclawproject.org.uk/downloads/WhatIsJR.pdf
[2] Council of Civil Service Unions v. Minister for the Civil Service [1985] AC 374.

central principle of administrative law (Craig, 1998). However, there is a different perception of JR. Yap & Lau (2011) relates PIL to public wrongs and refers Judicial Review (JR) as a litigation process to challenge and correct public wrongs committed by governmental bodies. The UK rule of law relates it to the law of public interest, whereas Hong Kong, generally based on the old English rule of law, refers JR as a court proceeding to clarify the scope of court jurisdiction as well as the relationship between the government bodies, the rule of law and the constitution (Olley, 2003; Lui, 2007). Yap (2011) distinguishes Public interest litigation (PIL) with two types of wrongs, generalized grievances and specific grievances. The first bears common interest of the society whereas the second bears only a segment of society directly suffers the wrong. The threshold stage of PIL is to seek leave for JR. The considerations of PIL are based upon whether the issue is of public importance, whether the applicant has the right to seek JR, and whether the applicant has a genuine interest in the vindication of the alleged wrong, and it is important to make clear that the case is not private interest litigation (Yap, 2011). However, the doctrine of *ultra vires* is not without problem. It imposes frictional intention and is incomplete and fails to explain JR's jurisdiction over non-statutory bodies; and in Hong Kong, the friction is created between the legal system and the Basic Law (Lui, 2007).

According to the Public Law in UK, if the application is successful, the court has the option for "quashing orders", "prohibiting orders", "mandatory orders", "a declaration", "an injunction", or "damages". According to the law in Hong Kong which is also based on common law, the relief to be sought from a judicial review can be "Mandamus", "certiorari" (quashing orders), "prohibition", "declaration", "injunction", "damages", or "interim relief" . "Mandamus" is an order compelling the respondent to perform an act specified in the order of the court, which is the nature of a public duty or obligation, but such act or obligation must be specified in the application, while "certiorari" means quashing order. The term follows the old English rules (Olley, 2003). "Interim relief" refers to the possibility of an interim order before the application for judicial review is decided. It can be seen that this additional administrative procedure is provided in the system in Hong Kong to help saving resources before reaching a decision.

3 The Project Case

The HZMB (Hongkong-Zhuhai-Macao Bridge) **Case:** In this case, the challenge was put forward by one local resident for judicial review in the Court of First Instance to the Environment Protection Department in approving the Environmental Impact Assessment Report and subsequently issuing the environmental permit for the HZMB project.

The significance of the case cannot be understood without mentioning the nature of the project. The Hongkong-Zhuhai-Macao Bridge (HZMB) connects three locations in the Pearl Delta region, Hong Kong Lantau Island, Guangdong Zhuhai and Macao, and is a mega-sized infrastructure project involving cross-border facilities linking sea and land routes. The HZMB project involves a 29.6 km dual 3–lane carriageway in the form of bridge-cum-tunnel structure. The Main Bridge runs from an artificial island off Gongbei of Zhuhai to an artificial island west of Hong Kong. The construction of the overall facilities is estimated to be over 70 billion Hong Kong Dollars (or US$8.97 billion). The

HZMB project is complex in nature and difficult to build in terms of the technical methods adopted for construction and engineering works. It involves planning aspects like site locations and alignments affecting the use of land, environmental aspects such as from changes in sea currents affecting the life of Chinese White Dolphins to air quality affecting nearby sites and the neighbouring residents. The project constitutes a group of work sections to be let separately. Nine work sections constituting preliminary design, detailed design, site supervision, quality management type of consultancy contracts together with the construction contract of the tunnel and artificial islands have already been let (May, 2012), and the other work sections are in the tendering channel including the construction of the Main Bridge.

The idea of constructing the bridge was firstly initiated by an infrastructure/engineering developer cum contractor in 1983. The planning of the bridge started in 2003 after the Hongkong-Zhuhai-Macao Bridge Advance Work Coordination Group was established. Pre-construction works was started in 2009, and the construction of the HZMB commenced in 2010 and has been expected to be completed in 2016. For a project to be constructed on new land is without doubt highly uncertain and complex. The site locations and road/bridge alignment have been changed since their initial planning in 2005. With the increased awareness of constructed facilities on the environment and in particular the pollution aspect, quality of air has aroused public interest. Even though HZMB has opened to public consultation and engagement, a juridical review of the case is called and caused surprise to many stakeholders involved in the projects.

4 The Intervention Case[3]

The construction of HZMB started in 2010 was suspended by a legal intervention relating to environmental law in early 2011 at a time when the dredging project of the artificial island was 90% completed. The intervention was triggered off by an elderly lady Ms Chu who claimed that she had diabetes and heart disease and lived close to an air sensitive receiving areas near the HZMB project. Ms Chu applied for a judicial review for the validity of the environmental impact assessment (EIA) report prepared in October 2009. Two issues were brought to the attention of the High Court:

- whether the Director of Environmental Protection Department has properly discharged her statutory duties and functions under the Environmental Impact Assessment Ordinance, Cap. 499 ("the EIAO"), in respect of part of the works forming the proposed HZMB project.
- whether the air quality impact of two of the projects connected with the HZMB was properly assessed in the environmental impact assessment reports for those projects.

In complying with EIAO, the project proponent needs to apply to the Director for an EIA study brief (s.5(1)a of the EIAO) based on the guidelines laid down in Section 3 of the Technical Memorandum. Once the study brief is issued by the Director, the project

[3] Chu Yee Wah v Director of Environmental Protection, HCAL 9 of 2010
http://www.epd.gov.hk/eia/english/content/files/HCAL_9_2010.pdf

proponent is to prepare the EIA report (s.6(1) of the EIAO). The environmental impact assessment report was approved in Oct 2009 and the environmental permit was issued the next month. There are seven issues applied for judicial review:

Issue 1	Absence of quantitative 'stand-alone' analysis
Issue 2	Lack of presentation of input data in PATH model
Issue 3	2031 as reasonably worst-case scenario
Issues 4 & 5	Failure to assess ozone and SO_2
Issues 6 & 7	Public health impact

5 Legislation relating to Environmental Law

Environmental law in action in Hong Kong comprises law and regulations including environmental legislation, compliance guides, environmental standards and compliance. Environmental Impact Assessment Ordinance (EIAO) was implemented on April 1998. Its purpose is to avoid, minimise and control the adverse impact of the environment of designated projects, through the application of the environmental impact assessment (EIA) process and the environmental permit systems (EPD, 2009). The legislation is administered via EIA (Appeal Board) Regulation, EIA (Fees) Regulation and EIAO (Amendment of Schedule 2) Order 1999 to provide environmental law and regulations for public interest of the built environment.

The "designated projects" requiring environmental permits are stated in the Schedule 2 of the EIAO and these include roads, railways and depots; airports and port facilities, reclamation and miscellaneous such as projects including new access roads, railways, sewers, sewage treatment facilities, earthworks, dredging works and other building works partly or wholly in an existing or gazetted proposed country park or special area, a conservation area, an existing or gazetted proposed marine park or marine reserve, a site of cultural heritage, and a site of special scientific interest. Thus an infrastructure project is required to provide environmental impact assessment report and an environmental permit before construction work is commenced.

5.1 The Documentary Reference

The project applicant seeking for an environmental permit shall prepare an environmental impact assessment report according to Environmental Law Cap.499 Section 6(1) with the following requirements:

(a) the environmental impact assessment study brief; and
(b) the technical memorandum applicable to the assessment

Thus the technical memorandum and the study brief are important documentary reference for the application. According to Environmental Law Cap.499 Section 16 (1), the technical memorandums are to set out principles, procedures, guidelines, requirements and criteria for:

(a) the technical content of a project profile;
(b) the technical content of an environmental impact assessment study brief or

environmental impact assessment report;
(c) deciding whether a designated project is environmentally acceptable;
(d) deciding whether an environmental impact assessment report meets the requirements of the environmental impact assessment study brief;
(e) deciding whether the Director will permit an applicant to apply directly for an environmental permit under section 5(9), (10) or (11);
(f) resolving conflicts on the content of the environmental impact assessment study brief and the environmental impact assessment report;
(g) taking advice from other authorities;
(h) deciding what is a material change, addition or alteration to an environmental impact or to a designated project;
(i) the issue of environmental permits;
(j) the imposition of environmental monitoring and audit requirements for designated projects as conditions in environmental permits.

5.2 Impact on the Environment

The project proponent had to do three things: describe the possible impact of the project on the environment, consider the major elements of the surrounding environment, and propose measures to minimise environmental impact on the possible severity, distribution and duration of environmental effects. Therefore, the proponent has to outline the processes and information involving emissions and discharges, and describe the environmental impacts or issues that may arise during the construction, operation or decommissioning of the project.

What constitute ambiguity are the measures to minimise environmental impact on the possible severity, distribution and duration of environmental effects in respect of the beneficial and adverse effects, the short and long term effects, the secondary and induced effects, the cumulative effects and the trans-boundary effects whenever applicable; but these requirements or measures are still undergoing development and will change at times between application and implementation as it is not unusual that planning (when application is made) is carried out several years before the actual implementation. While there may not be similar projects to refer, or the focus of public interest and political sensitivity change, it is difficult to predict other implications at the time of submitting project proposal and EIA applications. In other words, there is an administrative gap, which is also a time gap for understanding the environmental impact.

5.3 Evaluating the environmental impact for the designed projects

For the evaluation of the environmental impact, it is clearly not a case questioning procedural justice according to the detailed administrative procedure in the system, but rather to what extent that EIA should be carried out to mean ‘sufficiency’. In a detailed analysis of the process, it was noted that the end product was assessed but not the process creating the product, meaning that the construction was not assessed on the impact of ozone, sulphur dioxide and suspended particles, which was considered in the JR case unreasonable and illegal according to the environmental protection law.

This judicial review did not concern matters of procedural fairness or the lawful discretion of the Director. The Technical Memorandum and the Study Brief was not the subject of challenge in this judicial review. These documents were therefore not construed as legislative instruments. Thus the decision was made upon whether the requirements are met, and the JR case was directed to the Environmental Permit issued by the Director of the Environmental Protection Department.

6 Key Issues of the Intervention

Two key issues on public interest are raised in the case. The first is the public interest in the protection of the environment upon which the quality of life in Hong Kong will depend. The second is the public interest in ensuring that major designated projects are brought to fruition in a timely and efficient manner. The subject in debate is mainly grounded on the first issue, whereas the second issue is to be covered by a revised budget to be approved by the Financial Committee.

6.1 The result

In March 2011, Hong Kong High Court held the judicial review and declared the EIA reports invalid and requested that the Director of Environmental Protection Department to revoke the environmental permit. The ruling was that there was no separate assessment on the air, and therefore did not meet the requirements of the research outline and technical memorandum. The contention is that if the report did not meet the requirements, the director should reject it. The claimant representative claimed that:

> "the government should not abandon the effective supervision like protecting the ecology and public interests through environmental assessment for the economic growth and regional integration."[3]

6.2 Judgment made[3]

[4]The judgment made for the case is that the applicant's contention on Issue 1 is accepted whereas the contentions on Issues 2 to 7 are rejected. This is because there is an absence of a stand-alone analysis in the EIA Reports in complying with the Technical Memorandum and the Study Briefs. It follows that the Director had no power to approve the reports and to grant the environmental permits for the two projects in question. The court makes clear that this is not a judgment on the merits of the projects nor on the question of whether, despite any adverse environmental impact caused by those projects, but on the issue whether the adverse environmental impact of the projects are properly assessed and presented in compliant environmental impact assessment reports. Although the Judgment made in accordance with Issue No. 1 was allowed, however, the standard of requirement was arbitrary.

The judgment made was upon an argument that the government only provided the data of the impact of the project but not the data without the project. The government put the case to appeal. In September 2011, the Court of Appeal approved the draft outline zoning plan and the authorized reclamation works, and allows for the Director of

[3] Chu Yee Wah v Director of Environmental Protection, HCAL 9 of 2010
http://www.epd.gov.hk/eia/english/content/files/HCAL_9_2010.pdf

Environmental Protection Department's appeal. The EIA report and permits therefore maintain valid. The Financial Committee subsequently approved the revised budget for the construction of the HZMB in Nov. 2011, and the construction of HZMB restarted in Dec. 2011.

6.3 The appeal[5]

It was stated at the judgment made at the appeal that "It is not for the court to decide matters of policy" and that the environmental standards should be established under the ordinance. The judgment is based on two arguments in quashing order. Firstly, the project case comprises a series of projects and in this case three projects are related to the cross-boundary facilities, the bridge and two link roads. The argument is stand-alone analysis of each project or the cumulative effect of the project case. Secondly, the standard setting out the environmental requirement for the environmental impact assessment report is based on the technical memorandum and the study briefs. There is no mentioning of the requirement of a stand-alone analysis but the cumulative effect. The technical memorandum is taken as general requirement whereas the study briefs are taken as project-specific. Since the report is approved on 23 Oct. 1999, the standard requirement would be as the time of approval and not as any new standard prevailing at the time of application of JR in April 2011.

The criteria for evaluating air quality impact and hazard to life together with the guidelines for air quality assessment are included in the Annex document of the Technical Memorandum. While the detailed requirement accounting for the cumulative impact form the construction and operation of existing and planned/committed projects in the vicinity of the Project has been dealt with. Even for the phased implementation of the Project and the associated works. According to the judgment on the case, it is decided that the case is to base on the existing AQOs which represent the minimum standard of acceptable air quality or the "lowest common denominator", even though the Government's Air Quality Objectives Review means to enhance the air quality standard and impose more stringent AQOs, the court will not decide on matters of policy, whereas the judge stated that "It is not for the court to decide matters of policy" and that the environmental standards should be established under the ordinance.

7 Time and Cost Consequences of the Intervening Event

The construction was started on December 15th, 2009. The judicial review was initiated in late 2010. The construction works was then suspended and there had been a concern of the project cost increase. The increase of the project cost by 5% is estimated at the time of the intervention, and the cost could multiply if the applicant succeeded. This was because there were more than seventy projects on hold due to the legal interventions to the HZMB project. These similar projects would also require environmental assessment permits before commencing the works. There was no knowledge of the effect of cost and time consequences of these other projects.

[5] Chu Yee Wah v Director of Environmental Protection, CACV 84/ 2011

It had been suggested in Legislative Council to the government to hold a bid in advance and award contracts to the areas to construct in phases to catch up with the inland construction to minimise the impact of the suspension.

The increased cost was estimated to be 6.5 billion HKD (noted in Table 1), and can be referred as a time cost because it was targeted at accelerating the works to a compressed schedule such that the project can be completed on time in 2016. The cost covered increased labour resources, arrangement of overtime work and increased plant resources together with the increase in construction prices. Approximately half of the increased cost was contributed by labour, materials and plants, and approximately half of the increased cost was derived from the high tender price coming from the higher-than-expected risk assessment by tenderers together with the increased cost for construction resources and changed market conditions (see Table 2). The cost increase was therefore a result of the increased tendering prices and changes in construction methods.

The judgment of the JR was made on 18 April 2011, and the judgment of the appeal was made on 27 September, 2011. The construction of HZMB was suspended in April 2011 due to the intervening event and restarted in Dec. 2011. There was a delay of 8 months. The relevant tenders were called after 9 months and the tenderers became cautious and submitted tender prices higher than expected. The explanation given was that the target risk was high in addition to the adjustment of market price due to the time delay. The increased cost was adjusted to accommodate the inflation, the increased cost, the acceleration cost and the changed market conditions for the time schedule already planned for. With the time value adjustment, the increased cost for the construction of HZMB was 8.86 billion HKD (see Table 1), and the revised budget was approved by the legislative council in May 2012.

Table 1 Estimated cost for an eight year expenditure for the construction of HZMB at different times

Timeframe	Estimated total (pricing)	Estimated total (MOD)	Increase
Nov 2011	13,574.4 (Sept 2010)	16,189.9	2,615.5
May 2012	20,950.4	25,047.2	8,857.3

Table 2 Items of cost increase to HZMB due to the intervention

Item of increase	HK Dollars (million in MOD)	US$m equivalent
Price increase for time delay	3,270	419
Tender price increase	3,440	441
Increase in contingencies	670	86
Increase in price adjustment	1,480	190
Total	8,860	1,136

8 Analysis and Discussion of the Case

In the HZMB case, it is not about whether the case is lawful or unlawful, nor the decision is irrational, unfair or biased, but rather that the decision is comprehensive enough to take care of the interest of neighbouring residents if the project does not exist. What constitute ambiguity are the measures to minimise environmental impact on the possible severity, distribution and duration of environmental effects in respect of the beneficial and adverse effects, the short and long term effects, the secondary and

induced effects, the cumulative effects and the transboundary effects whenever applicable; but these requirements or measures are still undergoing development and will change at times between application and implementation, as it is not unusual that planning (when application is made) is carried out several years before the actual implementation. While there may not be similar projects to refer, or the focus of public interest and political sensitivity change, it is difficult to predict other implications at the time of submitting project proposal and EIA applications. In other words, there is an administrative gap, which is also a time gap for understanding the environmental impact.

For the HZMB project, the JR event and the increase in costs caught a lot of public attention. Based on Down's Issue-Attention Cycle (1972), there is a gradual realization from the "public" that the cost of "solving" the problem is very high. The "solution" may be viewed as a financial sacrifice to groups of people in the society, and benefits to others in fulfilling a fundamental goal of public interest. After the stage of "Realizing the cost of significant progress" (Down, 1972), the HZMB project is reinstated after the revised budget is approved. In the approval process of the Financial Committee, a large amount of paperwork and supporting documents had been produced with a view that there would not be any more 'unanticipated' event in affecting the economic efficiency of the project. There is then a gradual decline in the intensity of public interest in the problem, and people tend to have a mixed feeling about the intervening event and come to realize how costly to have a solution to the problem.

The implication of the judgment for the case of a project nature is that two issues are to be addressed in the administrative law. First, there should be a system of priority setting for significant "designated projects". Second, there should be a separate case management system to monitor intervening events. In the UK, it has been suggested to have mediation or other alternative dispute resolution methods to take over JR, but this suggestion is generally based on cases of social nature. When JR is applied to infrastructure projects, a special group should be assigned, or perhaps initiated to be formed when there is a need, to speed up the process and to support the court, to make rational, unbiased and fair decision. For the general principle of JR, the judgment of the case has adopted Wednesbury principle to rebut irrationality and unreasonableness for the issues about the documentary references and the air quality standards. Together with the doctrine of Ultra Vires, a reasonable judgment is made and the multiply time and cost effects of the environmental impact on a series of projects have been avoided. It is fortunate that the subject is not further complicated with the Basic Law which has been derived from a different legal system.

9 Conclusion

In the HZMB case, it is not about whether the case is lawful or unlawful, nor the decision is irrational, unfair or biased, but rather that the decision is comprehensive enough to take care of the interest of neighbouring residents if the project does not exist. It is a question of the time gap or the administration gap of the standard requirement, in the case, the air quality or the environmental standard, which can be resolved in the administration or the administrative law. It should however be noted that setting up proper systems is not sufficient as it may not catch up with the technology development

at the time. While JR is considered to be well-structured, transparent, with full publicity and a degree of predictability, debating social justice is an open system external to any projects that are complex, uncertain, long duration and labour-intensive. Therefore, managing projects of this kind should consider the intrigue nature and diversified interests the same way as making a policy so as to avoid unintended consequences (Ho, 2011) together with taking consideration of Down's Issue-Attention Cycle (1972) for the development of the intervening event.

The development of the case from start to end help explain that there are issues to be addressed beforehand. In this respect, public interest should be considered as a high risk factor in project planning because legal intervention arising from public interest is uncontrollable even though it can be handled in a way to minimize the effect. The applicant group should be made aware of the possible effect and collateral consequences of a project case, while the interests of other groups have to be considered as well. Since an un-anticipated event is one high risk factor that one may not be well prepared to solve the problem in time. In addition, it is also not too clear as how the increased cost is monitored at the implementation stage. Therefore, in managing cost and time matters for projects of a size as significant as the HMZB case, a project adviser or a team of advisors, with legal background, time and cost knowledge, should be assigned specifically to look after the projects. Above all, the case informed that the problem for the case was long established at a stage when the issues to be addressed had not been sufficiently attended to. If the conflicts are identified at an early stage and the stakeholders' interests and needs are accommodated and in particular those concerning public interest, the negative consequences can be avoided. Alternatively, the conflict can be handled differently such as mediation to avoid a minor problem to grow big.

Abstract:

The countries of Kenya, Uganda and Rwanda in East Africa have until recently viewed sanitation as a basic need left at the discretion of the state for progressive realisation subject to resources. In 2012, the United Nations General Assembly Resolution recognising the right to water and sanitation, and the United Nations Human Rights Council Resolution affirming the same rights, have put the states under a legal obligation to develop tools and mechanisms to enable rights approaches to implementing the right to sanitation. Express provisions in national constitutions and legislations and policies would be appropriate tools and mechanisms as they are foundational to providing for state agency duties, rights of groups, and responsibilities of all stakeholders in sanitation. Conducting a baseline study in the cities of Kisumu (Kenya), Kampala (Uganda) and Kigali (Rwanda) has established that sanitation, and the right to sanitation, has not been clearly understood and defined in legal frameworks and could be a factor exacerbating the sanitation crisis in the subject countries. Developing such legal frameworks centred on a right to sanitation is essential in the operationalization of the right to sanitation.

Key words:

Right to sanitation, informal settlements, East Africa

1. Introduction

Lack of improved sanitation is a crisis especially in the developing countries both in rural and urban areas of human settlements. About 2.6 billion people in the world[1] are not fully realising their human right to an adequate standard of living[2] because they have no access to

[1]See World Health Organisation and United Nations Children's Fund(UNICEF), Joint Monitoring Programme for Water Supply and Sanitation (JMP)"progress report on drinking water and sanitation special focus on sanitation, (2010,) p. 2 www.wssinfo.org. also found at http://www.who.int/topics/millennium_development_goals/en/ accessed on 24th of June 2012

[2]See A/HRC/10/6. In her report to the tenth session of the Human Rights Council, the independent expert(providing a detailed explanation of the decision to focus on sanitation) briefly explained that lack of access to sanitation has disastrous consequences for people's health, education, the economy, gender equality, and overall development.Lack of access to sanitation is overwhelmingly a problem of the poor, with women and children suffering the most.

improved sanitation[3]. The crisis in sanitation is said to be on the increase in urban areas with the creation of slums [4](otherwise referred to as informal settlements). Informal settlements have been defined as "residential areas where a group of housing units has been constructed on land to which the occupants have no legal claim, or which they occupy illegally; unplanned settlements and areas where housing is not in compliance with current planning and building regulations (unauthorized housing)"[5]. By the year 2010, the highest prevalence of informal settlements was found in sub-Saharan Africa where 62 per cent of the urban population were sheltered, followed by Southern Asia (35 per cent) and South-Eastern Asia (31 per cent). Particularly critical is the situation in conflict-affected countries, where the proportion of urban populations living informal settlements increased from 64 per cent in 1990 to 77 per cent in 2010[6].Rwanda is one of the countries in Africa where the aftermath of war and 1994 genocide has created a unique demographic dynamic as a result of an influx of refugees who returned to their home land after 35 years in exile and after genocide exacerbating the problem of water and sanitation infrastructure in urban areas. Most of the returnees opted to live, for security and employment reasons, in the capital city of Kigali where more than 70% of the city is occupied by informal settlements characterised by poverty and inadequate water supply and municipal sanitation infrastructures.

Although the right to sanitation has been recognised and acknowledged as being essential to the realisation of human rights by the United Nations General Assembly (UNGA) Resolution on 28th July 2010,[7]many countries that already have legal provisions for enforcements in sanitation have not utilised the imperatives of the right to extend services to the underserved and unserved areas such as informal settlements in urban areas of developing countries. Such areas are characterised by dense populations, lack of sanitation services, abject poverty and poor housing structures that are unplanned for by the state governments.

Following the (UNGA) Resolution, the United Nations Human Rights Council recognised that the right to water and sanitation is part of international law[8] and affirmed that the right is legally binding upon member states and called upon them "to develop appropriate tools and mechanisms to achieve progressively the full realisation of human rights obligations related to access to safe drinking water and sanitation, including in currently unserved and underserved areas."[9] However, there is neglect in understanding the implications of the right

[3] See JMP, (note 1),The classification of improved and unimproved sanitation isdeveloped by the JMP, for the purpose of monitoring access to sanitation, particularly in the context of the Millennium Development Goals and uses the term "improved sanitation" to refer to types of technology and levels of services that are more likely to be sanitary than "unimproved technologies."It considers excreta disposal systems as "adequate" as long as they are private and separate human excreta from human contact.

[4] See Lois Jensen United Nations;UN Statistics Division;2010,Millennium Development Goals website at http://mdgs.un.org ,the UN Millennium Development Goals website at www.un.org/millenniumgoals and the UN Millennium Campaign Office website at www.endpoverty2015.org states that "The number of urban residents living in slum conditions is now estimated at some 828 million, compared to 657 million in 1990 and 767 million in 2000".

[5] See Hofmann, P., Strobl, J., Blaschke, T. & Kux, H. 2008. 'Detecting informal settlements' in Elsevier[2009] volume 33 issue1 Accessed at http://www.elsevier.com/copyright.

[6]Lois Jensen note 4

[7] See the UN General Assembly Resolution A/RES/64/292; 28th July, 2010 that " calls upon states and international organisations to provide financial resources, help capacity-building and technology transfer to help countries, in particular developing countries, to provide safe, clean, accessible and affordable drinking water and sanitation for all".

[8] Universal Declaration of Human Rights (adopted on 10 December 1948) General Assembly Resolution 217 A (III) United Nations Document A/810, 71 (1948) (UDHR), International Convention on Economic Social and Cultural Rights (adopted on 16th December 1966) General Assembly Resolution 2200A (XXI) ,United Nations Document (ICESCR), and , International Convention on Civil and Political Rights (adopted on 16th of December 1966) General Assembly Resolution 2200A (XXI), United Nations Document (ICCPR)

[9] Human rights council resolution A/HRC/RES/15/9 on September 2010

to sanitation as an entitlement and a state obligation to create an enabling environment for minimum access to excreta disposal facilities (thus a toilet or adequate latrine) that can effectively prevent human, animal and insect contact with excreta, which ensure privacy and protect dignity, along with associated services such as sewerage or latrine exhaustion.[10]

Whereas states have the responsibility to enforce public health rules and regulations, local government by-laws, environmental laws on provisions of adequate and safe sanitation facilities by landlords , householders, institutions municipalities and water sanitation utilities and safe handling of human excreta before depositing it into the environment, the state government and regulating agencies in the water and sanitation sectors, are yet to comprehended to achieve universal affordable, and quality sanitation facilities and services to all citizens especially in urban areas.

With a focus on the urban informal settlements of Kisumu, Kampala and Kigali in East Africa,[11] there is a need to review the critical legal frameworks in these three countries to enable the progressive realisation of human rights obligations related to accessing sanitation in currently unserved and underserved areas. Examples can be drawn from what has worked in implementing this right in other jurisdictions. The national constitutions, laws, policies and enforcement practices need to be geared towards the full realisation of the right to sanitation so as to extend sanitation services to informal settlements.

2. Understanding sanitation in the countries of Kenya, Uganda and Rwanda

Improved and unimproved sanitation is a classification developed by World Health Organization (WHO) and the United Nations Children's Fund (UNICEF) under the Joint Monitoring Programme (JMP) to describe sanitation facilities that prevent human, animal and insect contact with excreta, which ensure privacy and protect dignity, along with associated services such as sewerage or latrine exhaustion contact with human excreta while unimproved sanitation is the converse[12]. The classification primarily focuses on the types of technologies and levels of service that are more likely to hygienically separate human excreta from human contact.[13]The JMP uses this classification as a progress monitoring mechanism of accessibility of sanitation facilities. See Table 1.1 below for a summary of what is perceived as improved and unimproved sanitation facilities.

Table1.1 Classification of improved and unimproved sanitation

3.Ventilated improved pit latrine (VIP)	3 Open pit latrine without slab
4.Pit latrine with a slab	4 Bush or field or water body

The classification reveals open defecation in areas where people do not have sanitation facilities. Shared facilities on the other hand, in are where more than two or three households share one sanitation facility. The shared facilities are not classified by both JMP and the Water Supply and Sanitation Collaboration Council (WSCSC) as improved.[14]The implication of this is that there is more unimproved sanitation in the African case study cities than reported. However, the countries of Kenya, Rwanda and Uganda, do not seem to have delve beyond the classification of improved and unimproved sanitation facilities, in order to understand the sanitation crisis and issues that prevent access to improved sanitation. Such issues for instance, include increasing urban populations that are unplanned for, by municipal councils for basic services. The three selected cities for this paper fit the description given to third world cities as "having two distinct sectors of 'formal and informal', 'urban and peri-urban' also known as 'squatter settlements', 'shantytowns', 'urban slums', or 'illegal settlements."[15]

Other issues include old regulations insisting on prove of secure land tenure before connection to net-worked sanitation systems or other onsite improved sanitation systems such as septic tanks and Ventilated Pit Latrines (VIP). High poverty levels and utility networks and sanitation service providers are reluctant to invest in illegal settlements for instance on wetlands usually inhabited by poor populations at the same time governments not enforcing environmental regulations to allow only appropriate sanitation options for such terrains in order to protect health, and environment from contamination by human waste.[16]

Other unattended to issues include , failures to enforce rules and regulations on landlords and householders to provide adequate sanitation facilities to households leading to sharing of dilapidated facilities by most households in the informal settlements. Due to poor superstructures and unclean conditions, there is rampant defecation in urban informal settlements. This study argues that the unimproved sanitation situations are due to a lack of incorporation, implementation and enforcement of the rules and regulations that enable improved sanitation by the states, and that this is due to a lack of understanding of the human right to sanitation imperative to create an enabling environment for access to safe and adequate sanitation.

2.1 Kenya and Kisumu

The Kenya National Bureau of Statistics reported[17]that, Kisumu East district (which, at the time of census in the year 2009, was the only district covering Kisumu City Council (KCC)), was one of the most densely populated districts in Kenya, with a total population of 473,649,[18]and a

[17] Government of Kenya; *Population and Housing Census* 2009 *A, B, C and VII. Report* 2010; Nairobi: Kenya National Bureau of Statistics (KNBS).

[18] See Government of Kenya; Kenya National Bureau Of statistics (KNBS 2009), 2009 Census report.

growth rate of 2.8%. This rapid population increase was attributed to migration, natural increase and the expansion of the municipal boundaries from 19 km^2 in 1969 to 297 km^2 at present[19] to include peri-urban areas. The physical expansion of KCC has not been guided by any form of urban planning. Development is said to be a "night mare….."[20]
About 60 per cent of the population is reported to be living in eight gazetted peri-urban informal settlements[21] which have a high rate of tenancy. Nyalenda A and B and Manyatta B, are on wetlands and largely have black cotton loose soils making construction of sanitation facilities difficult.[22]Some housing structures in the eight informal settlements are on government land and some on road reserves or on private freehold tenures and leasehold tenures. Table 1.2 below is an estimation of sanitation coverage for Kenya.

Table; 1.2 Estimated Urban Sanitation coverage for Kenya

(Source: WHO/UNICEF Joint monitoring report JMP, 2010)www.wssinfo.org

YEAR	IMPROVED	SHARED	UNIMPROVED	OPEN DEFECATION
1990	27%	42%	28%	3%
1995	28%	43%	26%	3%
2000	30%	45%	22%	3%
2005	31%	46%	21%	2%
2010	32%	48%	18%	2%

In Kenya as depicted in table 1.2 sanitation progresses from 31% in the year 2005 to 32% in could only be read as negligible since at the same time, shared facilities increased as well as unimproved facilities increased and open defecation remained constant. This clearly shows very slow progress in improvement in access to sanitation in the country. These figures are for both rural and urban areas of the country of Kenya.

The municipal council of Kisumu is the owner of infrastructure to sewerage drains on sanitation services such as the sewer lines and treatment plants which although have been leased to the Lake Victoria Water service Board (LVWSB) for the use of a private company known as Kisumu Water And Sewerage Company (KIWASCO). The company is wholly owned by the Kisumu City Council. Only 10% of Kisumu is served with sewerage systems. This covers only part of the planned areas of the city. The informal settlements rely on overused and poorly maintained pit latrines. Table 1.3 below shows the mode of human waste disposal in the city council of Kisumu.

Table 1.3 Mode of human waste disposal informal settlements in Kisumu (Kenya)

(Source;Maoulidi M. 2010)

Mode of Human Waste Disposal	**Percentage Of Households**
1.Main Sewer	1.3%
2.Septic Tank	0.7%
3.Cess Pool	0.7%
4.Pit Latrine without slab or not covered	80.1%
5.Bush	17.5%
6.Other/ water bodies	0.3%

Pit latrine without slab or not covered is included in the definition of unimproved sanitation as it does not keep away flies and smell. The on-going 3K-SAN research has begun to reveal that up to 1.3 % of sewage can leak into the environment while a good portion of the 0.7 % septic tanks is built without reference to an engineering specifications or control of the Kisumu city council and overflows into the environment. The on-going research is revealing evidence of open defecation and incidences of emptying of exhausted sludge from pit latrines into bushes, open spaces and water bodies in the informal settlements.

2.2 Uganda and Kampala

The city of Kampala's physical layout and creation of informal settlements with inadequate sanitation is attributed partly to its history dating back to 1600s when it was established as the Capital or (Kibuga) of what was then Buganda Kingdom. In the Buganda agreement of 1900 the British crown and leaders of the Buganda Kingdom, who were then Britain's ally, divided the country between them. The effect of this agreement on the land tenure system is that the area around Kampala was split into two: one part being administered by the Buganda Kingdom the Kibuga; and, one part by the British. The Kibuga was separated from the municipality and had a different land tenure system (mailo).

The Kibuga housed a highly traditional culturally regarded urban African community and was growing, with unplanned structures and dwelling units devoid of toilets and water supply, drainage, sanitation and solid waste management systems[23].Kampala has continued to have a dual urban form, which is attributed to the separation of the local Kibuga from the township or municipality. The former was largely unplanned and unsanitary while the latter was fully planned and highly controlled. Kampala City Council (KCC) has been blamed for failure to implement/enforce planning schemes. Responsibility for this is also placed on

[23] Stephen W. Giddings; International Housing Coalition 109.street N E. Suit 480 Washington D C 2002 accessed at info@intlhc.orgwww.intlhc.org

continued political interference, conflicting land use policies, and uncoordinated planning between KCC and the Ministry of Local Government[24].Thus there is growth of unplanned informal housing, and challenges related to solid waste accumulation, wetland encroachment and destruction, water pollution and changes in land use that are reducing the ecological services from the natural environment of the metropolitan area.[25] As a result, the living environment of the urban poor in the city is deplorable with poor sanitation, inadequate housing, poorly managed solid and human wastes, increased water pollution and reduction in ecological services[26]. Table 1.4 below give the sanitation coverage for Uganda. Please note that the coverage is for both rural and urban areas.

Table 1.4 Estimated Urban Sanitation coverage for Uganda

(Source: WHO/UNICEF Joint monitoring report JMP, 2010)*www.wssinfo.org*

YEAR	IMPROVED	SHARED	UNIMPROVED	OPEN DEFECATION
1990	32%	48%	17%	3%
1995	33%	48%	17%	2%
2000	33%	49%	16%	2%
2005	34%	50%	14%	2%
2010	34%	50%	15%	1%

In Kampala some informal settlements are on gazetted wetlands and are therefore declared illegal due to conservation law. Some informal settlements are on privately owned freehold and leasehold tenures that although not illegal are not under the jurisdiction of the Kampala city council obligation to plan those privately owned lands and provide services.[27]The authorities do not approve or regulate sanitation facilities in illegal settlements as they are viewed as temporary waiting for eviction and demolition. This raises the issues of pollution control from private properties. The conditions of sanitation facilities in the informal settlements in Kampala are very poor as shown in table1.5 below.

Table 1. 5Condition of sanitation facilities in informal settlements of Kampala, Uganda

(Source: Okot Okumu 2008)

Observed condition	Health and safety implication
Unclean condition with observed faeces and wet floor, bad smell, no hole cover	Risk of disease transmission by contact contamination and transmission agents like flies.
Flies within and around the sanitation facility, cockroaches and rodents	Risk of disease transmission by the observed agents
No sanplats or slabs	Risk of accidental collapse
Too close to housing and water points	Risk of water pollution, disease transmission
Dilapidated state of the sanitary structures	Risk of environmental pollution, lack of safety of users, disease transmission
Sullage from bathing and urinal shelters discharged in open drains, grey water pools	Risk of disease transmission by contact contamination especially among children, environmental contamination including water points
Faecal matter disposed in polyethylene bags, faeces littering compound and waste dumps	Risk of disease transmission by contact contamination especially among children, environmental contamination including water points
No hand washing facility at latrines	Risk of human to human contamination

2.3 Rwanda and Kigali

At independence in 1962, Kigali's population was 6,000. Since then, the City has experienced a high population growth rate resulting in an urban population estimated at 44 per cent of the total urban population in Rwanda. The population growth has occurred, however, without adequate physical planning and with unplanned urban growth, resulting in sanitation problems with significant implications for public health, especially for the urban poor due to inadequate and unsafe drinking water, poor drainage and sanitation conditions, solid waste

disposal hazards and construction in inappropriate and hazardous areas due to unplanned urban development. It is estimated that 80% of urban dwellers in Rwanda live in informal settlements.

In the City of Kigali, access to sanitation is a challenge even in middle and high-income households. This situation is worse in informal settlements where the high density of housing increases the negative health implications of both open defecation and unregulated emptying of pit latrines. This is due to the fact that the sanitation chain is poorly organized and regulated. The lack of private incomes is exacerbating the situation. Poverty in the informal settlements creates difficulties for Community Based Organisations and companies to grow to invest in sanitation infrastructures since investments returns may be difficult to realise. Re-use of faecal matter is limited to prison institutions and are not affordable for poor households in informal settlements. Table1.6 below shows sanitation coverage in Rwanda.

.

Table 6 Estimated urban Sanitation coverage for Rwanda

(Source: WHO/UNICEF Joint monitoring report JMP, 2010)*www.wssinfo.org*

YEAR	IMPROVED	SHARED	UNIMPROVED	OPEN DEFECATION
1990	69%	24%	4%	3%
1995	64%	23%	11%	2%
2000	60%	21%	17%	2%
2005	56%	20%	22%	2%
2010	56%	18%	29%	1%

Decentralized, on-site sanitation systems are the only mode of excreta management systems that exist in Kigali while informal settlements of Kigali are characterised by traditional pit latrines .The large number of pit latrines in informal settlements makes it difficult for inspectors to ensure sanitation is up to public health and environmental standards. Table 1.7 below is a finding of mode of human waste disposal in two informal settlements in Kigali that are research sites for the 3KSAN project.

Table 1.7 Mode of human waste disposal informal settlements of city of Kigali

Source: (strategic marketing research and consulting, 2011)

Water and Sanitation Services	**Kimisagara** **% of households**	**Gatsata** **% of household**
Main water supply is piped water	98%	69%
Outside pit latrine	84%	71%

Indoor flush toilet	3%	4%
Outdoor flush toilet	2%	3%
Households with own latrine (sum of the three figures above)	89%	78%

From the tables it is evident that progress has occurred in accessing improved sanitation services. However, it has been noted that the progress largely bypasses the urban poor living in slum conditions in developing regions.[28]

The city of Kigali is undertaking major land reforms and resettlement policies of informal settlements by re-locations and upgrading. This will have an impact on sanitation services in the future.

3. The implications of the right to sanitation in legal frameworks of Kenya, Uganda and Rwanda

The governments of Kenya Uganda and Rwanda are signatories to international conventions and regional treaties that have provisions in favour of the right to sanitation in an implied manner.[29]These three countries are bound by the international law on the right to sanitation.[30] The international law is "a solid basis for holding the governments accountable for protecting the full spectrum of human rights of all citizens including those in informal settlements and for promoting national legislative, policy and other initiatives which comply fully with the international standards that the States have ratified"[31].With the recognition of the right to sanitation in international law, the countries need to have constitutional express provisions for the right to sanitation to operationalize the right to sanitation. Entrenched constitutional provisions have been said to 'enable further actions including the development of legislation, improved enforcement in courts, and generate political discourses; enactment of legislation is necessary to specify the duties of service providers and rights entitlements of individuals. In the case of Rwanda for instance, where many institutions are in charge of sanitation with almost similar mandate, express provisions in legal frameworks may lead to accountability.[32]

The areas for review in constitutions, key laws and policies to expressly provide for components of the right to sanitation, include: recognition and entitlements of the right to sanitation to all people, allocation and availability of sanitation facilities and all related services, safe and good quality of sanitation facilities and services, affordability of facilities and related services; physical accessibility, non-discrimination, cultural acceptability and attention to marginalized and vulnerable groups, participation and access to information, monitoring and complaint procedures and international cooperation[33]. It is beyond the scope of this paper to review all key legal frameworks in all thematic areas. In reviewing the law, states are to ensure that persons whose right to sanitation has been denied, have access to effective judicial, administrative or other appropriate remedies at the national level, and should be entitled to adequate reparation.

3.1 Right to sanitation in legal frameworks of Kenya

Kenya has expressly provided for the right to sanitation in article 43 1(b) of the Constitution 2010 as follows:

> "Every Kenyan is entitled to adequate standards of housing and reasonable standards of sanitation."

It has also provided for easy access to justice in the courts in article 22 of the Constitution 2010 to enable the indigent whose rights are violated. In the event they are not able to come to court as individuals they may do so as the subject of public interest litigation. This has happened in other jurisdictions[34].The right to sanitation has however not been incorporated into legislation. In South Africa this has been the case, and has led to easy implementation of minimum requirements of sanitation services and agitation in courts for socio economic rights.[35]As a result of the express provision of the right to sanitation in the constitution in Kenya the civil society has become very active in several in public interest litigation to agitate for enforcement of social economic rights including sanitation and against evictions from informal settlements[36].

The laws of Kenya need a review to be in tandem with the constitutional provisions of the right to sanitation. These includes the Local Government Act 1963[37] of Kenya which provides that "the applicant for development of building means the owner, lessee or occupier of land or premises and includes his duly authorised agent or representative"[38] implying that if one has no title or access to secure land tenure, one will not succeed in applying for a development plan for development of a dwelling place with a sanitation facility that is

[38] See government of Kenya Physical Planning Act (building and development) (control) rules 2 , 1998

approved by the law. In the case of informal settlements, most tenants would be eligible as occupiers to make the investment, however, are hampered by the tenancies being unwritten.

In the City Council of Kisumu, developments of properties in informal settlements can only enjoy access to sanitation facilities such as sewer lines, depending on the proximity of the property to other developed areas. Accessing sewerage lines remains a major problem, due to the small size of many of the plots and the narrow and unsystematic access roads that do not allow for construction of sewer reticulation. Installation of on-site sanitation that is regulated and serviced by the city council of Kisumu, Lake Victoria South Water Service Board,(LVSWSB) and Kisumu Water And Sewerage Company (KIWASCO), is by agreement where "the owner must install sanitation services specified by the water service provider in the water services regulations that only include "a VIP latrine, septic tank, French drains, conservancy tanks, specified in rules 100 to 103[39]. Stringent securities of tenure requirements to acquire the on-site sanitation as basic minimum sanitation service by the public utility in the informal settlements accompany these specifications[40]. This may raise issues of affordability. The law has not been reviewed to incorporate alternative technologies which have been piloted elsewhere in the country and are highly recommended for extension of minimum access of sanitation to the informal settlements.[41] Perhaps reviewed laws may enable installation of better workable and acceptable technologies in the informal settlements.

Constitutional protections of private property exist in Kenya with implications of high compensations costs to private owners to give way for public utilities such as sanitation systems for public use. The Government of Kenya at national local or county level may under article 66 of the Constitution of Kenya 2010,[42] "regulate the use of any land, or any interest in or right over any land, in the interest of public safety, public order, public health, or land use planning among others." However, under Article 40 (3) (b), in the event that such land is compulsorily acquired by the Government, it is required that " prompt payment in full, of just compensation to the person may be made; besides, the constitution allows any person who has an interest in or right over, that property, a right of access to a court of law.

3.2 The right to sanitation in legal frameworks of Uganda

The Constitution of Uganda 1995[43] does not expressly recognise the right to sanitation. The Constitution, however, provides that "the state shall take all practical measures to promote a good water management system at all levels and shall protect important natural resources, including land, water, wetlands, minerals, oil, fauna and flora on behalf of the people of Uganda"[44]. The other constitutional provision in Uganda relevant to sanitation is XXVII, that "every Ugandan has a right to a clean and healthy environment" and that "the state shall promote sustainable development and public awareness of the need to manage land, air and water resources in a balanced and sustainable manner for the present and future generations". Articles XVII states that society and state shall recognise the right of persons with disabilities with respect and human dignity.

[43] Republic of Uganda ; the constitution of the republic of Uganda as at 15th February 2006; Uganda printing and publishing corporation

[44] Article XIII Constitution of uganda 2005

Article XXI provides that "the state shall take all practical measures to promote a good water management system". With regards to sanitation, the city of Kampala has served its urban residents with sewerage systems, on-site sanitation in the form of septic tanks and allowed small scale sanitation service providers to operate exhaustion services in the informal settlements from pit latrines. However, there are a lot of constraints for the City Council of Kampala to extend sewerage mode of human waste disposal to the informal settlements, chief of which are the constitutional and legislative protections of private property ownership in the informal settlements[45] .

Control of orderly developments in the city by the city council of Kampala has been hampered by the land tenure rules in the Land Act of 1998[46] which recognize four types of land tenure systems in Uganda. Section 2 of the Act, stipulates that all land, "shall be owned in accordance with the following land tenure systems—(a) customary; (b) freehold; (c) mailo; and (d) leasehold. Most land in Uganda—70% to 80%—is held under undocumented customary tenure. There are constitutional protections of these private property ownerships in informal settlements of Kampala. Article 26 of the Constitution of Uganda 2005, protects citizens of Uganda against deprivation of private property by providing that citizens have "a right to own property either individually or in association with others and shall not be compulsorily deprived of property or any interest in or right over property of any description except where the following conditions are satisfied—(a). The taking of possession or acquisition is necessary for public use or in the interest of defence, public safety, public order, public morality or public health; and(b) The compulsory taking of possession or acquisition of property is made under a law which makes provision for— (i) prompt payment of fair and adequate compensation, prior to the taking of possession or acquisition of the property; And (ii) a right of access to a court of law by any person who has an interest or right over the property"[47].

These provisions have been noted[48] to hamper extension of sewer lines and investments in sanitation infrastructures in Kampala's informal settlements because of high costs of compensation to landowners, and other tenure claimants before one can install drains and access roads to interior premises. Any meaningful sanitation developments that have taken place in the recent past in the informal settlements has been through leasing of property from landlords for a period of twenty years in order to install public toilets. Even then, the political balance between landlords and the council has meant that, in fact, the council has been able to exert little control of facilities.[49]

3.3 The right to sanitation in legal frameworks of Rwanda

The Constitution of Rwanda 2003 provides for environmental protection in article 4 which states that "each citizen has the right to a clean and healthy and satisfying environment." there is also a corresponding duty on "each individual to protect, conserve and promote the environment, which is reinforced in the Environment Protection and Management Act

[45] Nyakaana, J.B; Sengendo, H & Lwasa, S. (2007). Population, Urban Development and the Environment in Uganda: The Case of Kampala City and its Environs. Paper presented in a conference, Nairobi: Kenya

[47] Government of Uganda Constitution of Uganda 2005
[48] Constitution of Uganda 2005
[49] Nyakaana, J.B; Sengendo, H & Lwasa, S. (2007). Population, Urban Development and the Environment in Uganda: The Case of Kampala City and its Environs. Paper presented in a conference, Nairobi: Kenya

(EPMA) number 4 of 2005.Under article 4 of the constitution, the government has the overall responsibility to conserve, protect, and promote the environment by implementing and enforcing EPMA 2005 which it does through Rwanda Environmental Management Authority (REMA).

Under article 74 of EPMA, REMA is mandated to investigate and prosecute offences against environment as stated in the laws. In article 60, REMA shall carry out policing in collaboration with the people of Rwanda who have a duty to keep the environment clean, the decentralised entities such as the City Council of Kigali, district sectors and communities that shall be responsible for the implementation of laws, policies, strategies, objectives and programmes relating to protection, conservation and promotion of the environment in Rwanda. Article 62 stipules that decentralised entities have the responsibility of designing plans of collecting and treatment, piling of domestic waste, removal of any other waste in any possible way depending on its nature and quantity, its treatment and disposal.

Offences specific to sanitation are in Article 87 of EPMA, which prohibits construction of houses in wetlands (rivers, lakes, big or small swamps), in urban or rural areas and building of a sewage plant and any other buildings that may damage such a place in various ways". It further provides that "all buildings shall be constructed in a distance of at least twenty (20) metres away from the bank of the swamp. Article 3 of the (EPMA 2005) regulates the behaviour and practices of people who deposit; abandon or dump waste, material or who pour sewage in a public or private place while article 81prohibits among others, "dumping or disposal or damaging the surface or underground water; defecating or urinating in inappropriate places; spitting, discarding mucus and other human waste in any place. The penalty for these offences is "a fine ranging from ten thousand to one hundred thousand Rwandan franks except if such a place has been designated for dumping by competent authorities".

However, REMA reports that "Kigali is sinking under the weight of its rubbish and sewerage".[50]This situation may be explained by several factors including that Rwanda Environment Management Authority (REMA) and decentralised entities (City of Kigali, Districts and Sectors) which are responsible for law enforcement do not have sufficient qualified staff to deal with technical issues. Another factor is that, REMA has not yet published clear standards and guidelines for discharging wastewater in the environment; they do not have legal instruments for law enforcement. In addition, through the Organic Law on Environmental Protection, Conservation and Management, Rwanda Environment Management Authority is mandated to establish modalities and regulations for the collection and use of the environment-protection fees.

Conclusions

This paper set out to argue that there is neglect in understanding sanitation and defining the right to sanitation as an entitlement and a state obligation comprising, at a minimum, access to excreta disposal facilities (a toilet or adequate latrine) that can effectively prevent human, animal and insect contact with excreta, which ensure privacy and protect dignity, along with associated services such as sewerage or latrine exhaustion. We have seen that several factors or issues are causal to the creation of informal settlements where large populations are confined to inadequate standards of living due to unimproved sanitation. The classification into improved and unimproved sanitation is narrow for monitoring progress in accessing

[50]Government of Rwanda ; the Rwanda Environment Management Authority(REMA) Report on the status of environment , 2010

sanitation by unserved and underserved in informal settlements because it does not seem to reveal the real reasons causing large populations to have unimproved sanitation such as poverty, access to interests in land, uncontrolled urban development leading to cheap housing without appropriate sanitation facilities.

This paper set out to show that sanitation as a right, if formerly recognised in the legal frameworks, may lead to open channels for legitimate civil society actively to claim that right. In Kenya, the right has been expressly recognised in the constitution and there are further examples of cases from India and South Africa. On the other hand, in Uganda and Rwanda there is no express provision for the right to sanitation. It can be concluded that express provisions of the right to sanitation may lead to the activation of civil society to demand improved sanitation as has been the case in Kenya and India as demonstrated in the case law. Sanitation has been broadly grouped into wide environmental concerns in the case of Rwanda and Uganda encompassing protection of natural resources, such as rivers wetlands land, which understanding may obscure a focus and understanding of sanitation as management of human excreta and its safe management as defined herein above. There is no clear emphasis on sanitation as not only a public health issue but also as a right of its own standing in both Uganda and Rwanda. In the case of Kenya although the right to sanitation has been recognised it needs awareness rising to enable accountability from the government and other actors in the sector.

Acknowledgements

We are grateful to the 3K-SAN project sponsors and team for the work they have done on coordinating and conducting the workshops and field work and for all the discussions and desk reviews. Special thanks go to the governments offices of Rwanda, Kenya and Uganda in both national and local levels for allowing us do this research. Finally most thanks must go to the people of informal settlements in Kisumu, Kampala and Kigali who gave us their time to for group discussions which we hope will assist in achieving better standards of living.

A REVIEW AND CASE STUDY OF STRATEGIC CARBON MANAGEMENT IN UK HIGHER EDUCATION SECTOR

Muhammad Usman Mazhar[1], Richard Bull[2], Mark Lemon[3]

[1, 2, 3] *Institute of Energy and Sustainable Development (IESD), De Montfort University (DMU), The Gateway, Leicester, LE1 9BH, United Kingdom*

ABSTRACT

Climate change is arguably one of the greatest environmental challenges facing the world today, bringing organisations under increasing pressure from government, shareholders and stakeholders to reduce carbon emissions. The Higher Education (HE) sector has a significant social and economic impact and is not exempt from challenging carbon reduction targets, in fact, it is argued, should be demonstrating leadership in the field. The term 'carbon management' is popular in the literature but strategic carbon management (SCM) is an under-developed and under-researched area as it is an applied concept, especially within the HE sector. Scope 1 and 2 emissions reduction initiatives have received more attention than scope 3 thereby missing a significant opportunity for fully effective carbon reduction. These gaps have been identified through analysis of the academic and practitioner literature, reports, and websites. The study proposed in this paper will look into the gaps and possible future research direction of SCM in the HE sector through a case study of De Montfort University (DMU). It will explore how carbon emissions can be reduced strategically and develop a systematic and comprehensive strategic management approach to doing so. Finally this paper makes some provisional principles for transferable best practices for the HE sector.

Keywords: climate change, carbon management, higher education, stakeholders, strategic management.

INTRODUCTION

The motivation for this research comes from the widely-accepted need to greatly reduce the carbon dioxide and other greenhouse gases (GHG) emissions in order to mitigate anthropogenic climate change (IPCC 2007). The Stern Review report suggests that a 25% reduction below current levels of emissions is required in order to stabilize global CO_2 concentrations at levels that will not have very adverse impacts (Stern Review 2006). The UK government passed the Climate Change Act 2008 as its long-term legally binding framework to tackle climate change under its Kyoto commitment. Carbon management is moving up the corporate agenda and

[1] mmazhar@dmu.ac.uk
[2] rbull@dmu.ac.uk
[3] mlemon@dmu.ac.uk

organisations now understand the need to handle their emissions. It must be embedded through the business (Carbon Disclosure Project 2010).

The Higher Education (HE) sector is not exempt from this challenge and needs to play its part in both meeting the national carbon reduction targets and demonstrating the leadership (HEFCE 2010a). In 2005 the HE sector in England emitted 5.4 million tonnes of carbon dioxide and through pressure from the Higher Education Funding Council for England (HEFCE) is being strongly encouraged to show leadership by reducing its emissions (HEFCE 2011). Carbon management is slowly becoming a strategic management issue for universities' senior management due to HEFCE's carbon emissions targets and strategies. Guidance has recently been published by HEFCE on monitoring and measuring scope 3 emissions (Procurement, travel, waste and water) (HEFCE 2012) and universities like De Montfort University (DMU) are developing ambitious carbon management plans for scope 1, 2 and 3 emissions.

The aim of this paper is to identify a potential gap in the academic literature of Strategic Carbon Management (SCM) and discuss the potential role of the HE sector in achieving substantial carbon reduction. It starts with the history of carbon management and then introduces the issue associated with the development of SCM in the HE sector and then within DMU. It will consist of findings from the existing academic, non academic literature, policy and strategic documents. It also provides a systematic analysis and discussion on SCM within the HE sector and identifies themes and potential gaps to be further researched. The final part of the paper summarises the methodological and theoretical implications associated with SCM and makes recommendations for how this process can be moved forward.

CARBON MANAGEMENT

In recent years, the climate change and carbon management debate has dramatically risen up the public agenda. The emphasis in the past has been on the science involved, and communicating the extent humans are affecting the global environment; this is now widely accepted that humans are impacting the natural environment (Kolk & Hoffmann 2007). Over the last few years, some interesting studies on organisations' carbon management have emerged (Čadež and Czerny 2010). Liu (2012) states carbon management as any corporate effort to address and reduce the impact of a firm's business activities on climate change, although not all greenhouse gases directly relate to carbon but these are included in the definition of carbon management in terms of their carbon dioxide equivalents. The established measures of carbon management have focused on specific fields such as a reduction in GHG emissions, development of low-carbon technology and clean energy and the adjustment of economic structures. Organisational structure and business models have contributed to the progress of carbon management but step changes are still needed (Liu 2012).

Carbon management strategies provide an interesting research stream and Pino et al. (2009) put forward six components of them; verifying the data of greenhouse gas (GHG) emissions, setting and updating performance targets, identifying cost-effective emissions reduction, internal communication management, finding new business opportunities and adapting to market-based solutions. The acknowledgement of the growth of climate change and the subsequent business response of organisations is by no means widespread (Kolk & Hoffmann 2007). Debate still ensues as to why some organisations are responding to climate change and others are not. The literature on

carbon management and other associated issues remains in its infancy, and thus provides a good opportunity for further research (Jackson 2008). A study of corporate carbon strategies of Korean companies' suggests that companies have started considering the carbon issue in their overall strategic positioning. A comprehensive theoretical framework has been developed from the Industrial Organisations (IO) theory which divides carbon management activities into six categories: emission reduction commitment, product development, process and supply improvement, new market and business development, organisational involvement and external relationship development (Lee 2012).

Management studies claim that there is a business case for companies to address climate change through adequate carbon management strategies. Thus, climate change constitutes a business relevant issue and that companies are able to increase their competitiveness by implementing carbon management strategies (Busch and Wolfensberger 2011). Corporate carbon management is not limited to mitigation efforts internally but also comprises of supply chain optimisation, product-related improvements, and compensation activities (Busch and Wolfensberger 2011). Our initial analysis shows that there is an established literature on the corporate response to climate change and carbon reduction strategies. Other researchers have developed strategy frameworks. For example, Hoffmann and Weinhofer (2010) noted that we understand a company's CO_2 strategy as 'a pattern in action over time' intended to manage its direct and indirect carbon emissions. A framework is developed that conceptualizes a company's CO_2 strategy as the focus of one or a combination of several strategic objectives: CO_2 compensation, CO_2 reduction and carbon independence (Hoffmann and Weinhofer 2010). Horgan (2011) has also developed a carbon management hierarchy as shown below.

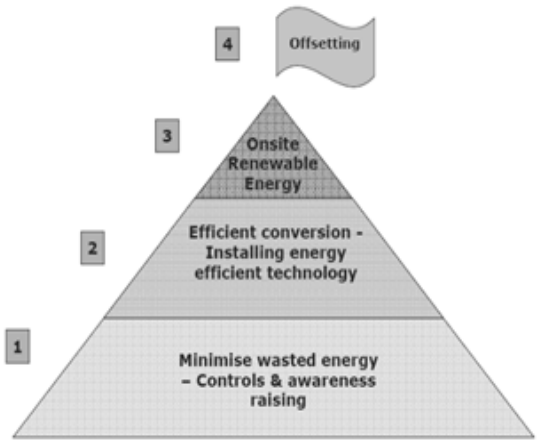

Figure 1: Carbon Management Hierarchy (Source: Horgan 2011)

STRATEGIC CARBON MANAGEMENT (SCM)

Research framework:

As climate change has emerged as a legitimate business concern; academics have attempted to gain a better understanding offirms' carbon strategies by characterizing their climate change response (Lee 2012). The actual and potential strategic impacts of climate change on companies are intensifying (Kolk and Pinkse 2005). Management research on the topic of corporate carbon strategies within the organisations is still a relatively new endeavour though a few studies have analysed

firms' responses to climate change from a strategic perspective. Yet most of the studies of corporate carbon strategies have examined large-sized and international firms (Lee 2012). Increasing regulatory pressure, public opinion, and environment oriented consumers and financial institutions have led companies to consider climate change in their strategic management (Hoffmann and Weinhofer 2010).

The strategic importance of carbon is expected to grow over the next ten years and will be embedded in the business as a long-term priority (Carbon Disclosure Project 2010). Strategic Carbon Management (SCM) is an approach to address the carbon and financial cost of an organisation's operations. Strategic management of carbon is complex and starts with understanding the ways carbon management can affect the organisations' activities – both tangible and intangible. For example, the operational aspects such as process efficiency and alternate energy sources, regulatory aspects, or possible impacts on company reputation based on stakeholder perceptions, carbon has the potential to impact the bottom line (Two Tomorrows Group 2012).

SCM provides an understanding of the way in which organisations are translating strategic issues into management actions in the context of their carbon impact. It is needed to examine the strategic response of organisations to the challenge of carbon reduction. Organisations need to consider climate change in a strategic context and to integrate carbon management issues into their long-term decision making process. SCM will provide an effective approach to issues such as capital costs of investment, strategic decision making, carbon reduction target setting, sourcing funding, building business cases and winning internal support in an organisation (Deloitte 2012). This is not simply about reducing the organisational carbon footprint, but taking into account

> *"how the organisation is thinking about carbon and thinking about what it needs to do for adaptation and contribute towards sustainable development in the context of the decisions and the duties it undertakes" (Barter and Bebbington 2011, p. 2).*

Managers and boards in most industries are beginning to come to terms with new realities of a carbon-constrained economy and emphasise to take a strategic approach. It helps to unearth opportunities to gain competitive advantage over your rivals by developing the strategies. The bottom line is that carbon, just like capital, human resources and products, is now a strategic part of the new competitive game (Schultz and Williamson 2005). A survey revealed that although 60% of the 2,000 responding executives thought that climate change was an important consideration within their company's strategy, translation into actions remained limited (McKinsey 2008).

Life cycle wide emissions:

Corporate carbon management is not only limited to mitigation efforts in the organisation but it also comprises of supply chain optimisations, product-related improvements, and compensation activities. A life-cycle context is relevant for corporate competitiveness and a framework of eight carbon management strategies has been developed based on the Industrial Organisations (IO) literature and each strategy of the framework contributes to the potential competitive advantage (Busch and Wolfensberger 2011). The companies are now aware of life-cycle wide thinking of assessing the environmental impacts because of the intensifying stakeholders' pressure to manage it (Busch and Wolfensberger 2011). Examples are the Carbon Disclosure Project (CDP) and the California Climate Action Registry (2009). Both accelerate the discussion on scope 3 emissions as per Greenhouse Gas Protocol

Standard (World Business Council for Sustainable Development (WBCSD) and World Resources Institute (WRI) 2004).

SCM routemap:

Ansoff (1980, p. 133) suggests that

> *"a strategic issue is a forthcoming development, either inside, or outside the organisation, which is likely to have an important impact on the ability of the enterprise to meet its objectives".*

What Ansoff (1980) suggests is that while firms might face a variety of issues (including those that are social), only certain ones are considered significant enough to impact the ability to fulfil corporate objectives. Horgan (2011) has provided a comprehensive SCM routemap detailing various strategic issues for public sector organisations to reduce their emissions. It involves the integration of various themes within the process; most common are low carbon culture, low carbon strategy, stakeholders' engagement, low carbon procurement, financial case, metering and monitoring and performance evaluation. It also involves a five step approach to carbon/energy management starting with senior management's commitment to the monitoring and controlling the carbon/energy performance. Environmental performance is a strategic issue and needs strategic intention which adds value in terms of strategic competitive advantage. Worthington and Patton (2005) in their studies of Small and Medium Enterprises (SMEs) in the UK screen-printing sector have discussed management decisions and implications lack in strategic orientation and innovative response is needed within the companies for both demand and supply sides benefits. We will now look at the role of SCM both within the UK's HE sector and a specific case study example.

STRATEGIC CARBON MANAGEMENT - HE CONTEXT

Overview of the Higher Education sector:

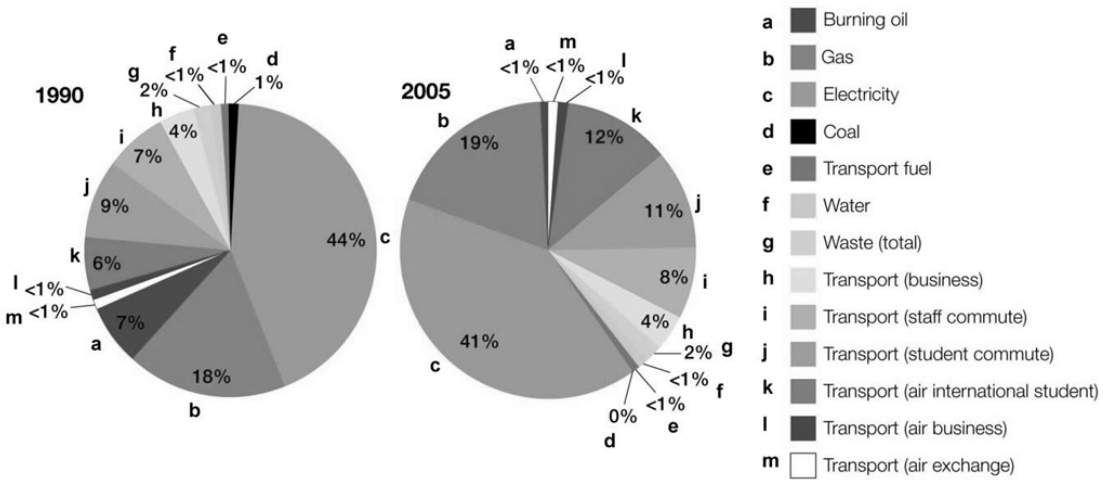
The context of the ongoing study is restricted to the UK HE sector and its ability to meet government's national and international binding targets. Worldwide, HE sector has expanded phenomenally; for example, since the 1960s, the UK HE system has expanded sixfold to >2.4 million students (Zhang et al. 2011). As a result, growth of physical infrastructure and services in the universities has led to a parallel impact on the natural environment in terms of carbon emissions. Many of the larger universities produce greenhouse gas emissions equivalent to small cities (Knuth et al. 2007).

Carbon reduction target and strategies:

The UK Government has ambitious targets to reduce greenhouse gas emissions by 80% by 2050 and 34% by 2020 against a 1990 baseline, together with 5 year carbon budgets for 2008-12, 2013-17 and 2018-2022 (Her Majesty's Stationery Office (HMSO) 2008). The HE sector is being encouraged to lead in this area as it is a significant contributor of carbon emissions in the public sector but also because of the privileged position universities occupy in being [it is hoped] centres of research excellence and cultivating 'thought leaders' for the future (HEFCE 2009). The Higher Education Funding Council for England (HEFCE) encourages Higher Education Institutions (HEIs) to adopt ambitious targets in its national carbon strategy (HEFCE 2010a). HEIs are compelled to set individual reduction targets for 2020 against a 2005 baseline for their direct and indirect emissions related to the use of fossil fuels and purchased electricity in their own buildings, stationary and mobile emission sources

(scope 1 and 2 emissions under the definitions of the GHG Protocol Corporate Standard; (HEFCE 2010b; WRI/WBSCD 2004)). Indirect emissions from procurement, business travel, and commuting among other relevant sources (scope 3 emissions) are not currently included in the targets. Figure 2 shows carbon emissions baseline during 1990 and 2005. It includes energy use within the estate (fossil fuel combustion – gas, coal, oil and electricity use), transport (institutions' own vehicle fleet, business travel and commuting), water; and waste. These results exclude procurement, which has a considerable indirect carbon impact, but the data for estimating these emissions is not readily available (HEFCE 2010a). The HE strategy requires institutions to undertake work to monitor and report these emissions, including the measurement of a baseline of procurement emissions by December 2012 and set a carbon reduction target by December 2013.

Figure 2: HE sector carbon emissions baseline – breakdown in 1990 (left) and 2005 (right)



(Source: 'Research into a carbon reduction target and strategy for Higher Education in England: a report to HEFCE' 2009)

The UK government has identified the HE sector as key to delivering carbon reduction with its Kyoto commitment and the Carbon Trust Higher Education Carbon Management programme is designed in response to this. HEFCE has produced guidance to the universities on how to produce carbon management plans which set out universities' strategic direction on carbon management. The majority of universities have carbon management plans which state their targets and strategies to manage their carbon emissions. HEFCE has also produced carbon reduction targets and strategy for the HE institutions and linked capital funding with the carbon performance of the institutions (HEFCE 2010a).

Scope 3 emissions:

HEFCE commissioned Arup, DMU and the Centre for Sustainability Accounting (CenSA) to work towards helping the UK higher education sector measure scope 3 emissions, supply chain (procurement), transport, water and waste related carbon emissions to form the part of an overall approach to reducing carbon emissions (HEFCE 2012). Good practice guidance is available for the sector which provides

 ISBN: 978-1-84219-840-7 .

Higher Education Institutions (HEIs) with information on how to quantify scope 3 carbon emissions. It aims to help HE sector to adopt efficient and effective data collection techniques and includes examples of good practice within the sector (HEFCE 2012).The HE sector is currently dealing with a plethora of initiatives intended to reduce energy use, carbon emissions, and other environmental impacts in universities and colleges (Hopkinson and James 2007). The HEI's can also make carbon reductions through their other business activities including teaching, research and public communications. While these can be categorized as 'Scope 4' emissions and are featured in the carbon management plans but it is not possible to measure the results of these activities (HEFCE 2010a).

STRATEGIC CARBON MANAGEMENT - DMU CONTEXT

Overview of De Montfort University (DMU):

DMU is based in Leicester, England and has approximately 21,585 students, 3,995 staff, and an annual turnover of £132.5 million (Ozawa-Meida et al. 2011). DMU acknowledges that its activities have an impact upon the environment and as an organisation it remains committed to a policy of reducing carbon dioxide and other greenhouse emissions. Therefore, DMU has made a commitment to move sustainability out of the 'green ghetto' and into the mainstream culture of its organization. A key objective is that within the next ten years the university aims to make a major contribution to society's efforts to achieve environmental sustainability and become a leader in the HE sector (DMU Strategic Plan 2011).

Policies and strategies:

This section outlines DMU's own approach which seeks to explore and embed carbon management into the strategic management process through the systematic analysis of the university's strategic documents. DMU has made a strong commitment to be a sustainable university and has set a strategic direction for carbon management. DMU has a cross-faculty and departmental Sustainable Development Task Force (SDTF) that has produced a Sustainability Strategy (2009) which sets out the overall sustainable development pathway for the whole university. The Sustainability Strategy (2009) highlights the importance of measuring and monitoring environmental performance and greenhouse gas emissions to implement an ambitious carbon reduction plan. DMU has developed relevant policies and strategies in all areas of environmental and greenhouse gas emissions management including Energy Policy, Green Travel Plans, Waste Management Policy, Procurement Policy, Biodiversity Policy and Carbon Management Plan.

Consumption-based carbon footprinting:

De Montfort University is the first university in England to calculate its consumption-based carbon footprints for the effectiveness of carbon management and progress of its policies and strategies. In August 2010, the university commissioned Arup to undertake a carbon footprint assessment using a consumption-based approach. The aim of the study was to quantify the overall carbon emissions within DMU, identifying actions to make quantitative reductions in greenhouse emissions. The total consumption-based emissions for 2008/09 were estimated to be 51,080 tCO2e (metric tonnes of CO2 equivalent). Building energy, procurement and travel contribute with 33%, 38% and 29% respectively to the overall emissions in academic year 2008/09 which runs from August to July (Ozawa-Meida et al. 2011). The World Resources Institute (WRI) has divided emissions sources in three 'scopes'. Scope 1 is direct

emissions that occur from sources owned or controlled by the organisation, for example emissions from combustion in owned or controlled boilers, furnaces, vehicles; scope 2 accounts for emissions from the generation of purchased electricity consumed by the organisation; scope 3 is all other indirect emissions which are a result of the activities of the company, but occur from sources not owned or controlled by the organisation, for example, commuting and procurement. Under the classification of the WRI/WBCSD Greenhouse Gas Protocol, scope 1, 2 and 3 emissions represented 6%, 16% and 78% respectively to the overall emissions in the academic year of 2008/09. DMU study has divided its scopes' emissions into the sub-categories.

Strategic approach:

DMU has set its own target for reducing emissions from energy use and own vehicle emissions by 43% by 2020 based on its emissions in 2005/6. There are also interim targets of a 12% reduction by 2012 and 29% by 2017 in order to ensure regular monitoring and progress (DMU Carbon Management Plan 2011). The university is committed to reducing its overall carbon emissions and has developed a comprehensive carbon management plan until 2020 using a baseline year of 2005, which indicates university's strategic approach. It has designed the following strategic themes in its carbon management plan.

- Strategic approach
- Monitoring, targeting and reporting
- Policy review
- Embedding activities on carbon savings
- Strategic investment

DMU has identified a number of different carbon reduction projects relating to the strategic themes and the implementation of these projects will aim to deliver the carbon reduction targets (DMU Carbon Management Plan 2011). Progress has already been made in reducing greenhouse gas emissions from the baseline year through a mixture of changes to the university estate and space management. The university has shown very good results in environmental and sustainability benchmarking schemes (Universities that Count& People and Planet's Green League).

DISCUSSION

This paper has provided an overview of the status of current Strategic Carbon Management (SCM) research and future opportunities. It has analysed three levels of literature starting from SCM in general to the SCM in the HE sector and DMU. It has identified a need for a systematic process for a SCM in HE sector and also the lack of theoretical insights in order to understand that how this process can be implemented by the universities' senior managers. The literature reveals that there is no direct empirical knowledge on why and how organisations integrate carbon management in their strategic management process. There is a vast literature available in the form of carbon management implementation plans and strategies in the public sector but no strategic carbon management focussed academic literature was found which indicates that the field is relatively under-developed and under-researched.

The term 'Strategic Carbon Management' (SCM) is undefined so far and literature is unable to identify the difference between carbon management and strategic carbon management which is an important question for researchers to investigate. SCM is an emerging research agenda based on the literature review of this wide academic discipline. As it has been discussed, strategic management of carbon is a complex organisational task and it must begin with understanding how carbon management can affect the business. Though carbon management is a strategic issue, there remains a need for a strategic management approach to abate carbon emissions. According to the GHG Protocol (2004) the government policies will not sufficiently solve the problem of carbon emissions. Strong leadership and innovation from business is vital to making progress. The literature on SCM is very sparse and some studies have focussed on the measures to reduce carbon emissions which also include technical measures and behavioural change strategies. Efficient carbon management strategies will help decision-makers to achieve carbon reduction targets in a cost-effective manner. A SCM framework needs to be developed by all universities as a catalyst for actions against carbon emissions which can guide senior managers in how they can contribute towards carbon reduction in their decision-making.

DMU measured its carbon emissions using a consumption-based approach but there is a real need to evaluate the advantages and disadvantages of the different approaches to carbon footprinting. There is a need to carry out a study which will help in developing an understanding that how SCM can be integrated in scope 3 emissions (supply chain emissions) and support senior management to manage its overall carbon emissions. Eisenhardt (1999) explained strategy as a strategic decision-making process and therefore, the ability to make quick, widely supported, and high-quality strategic decision is the cornerstone of an effective strategy. Thus, there is a need to understand the context and the process of strategic decision-making within the institutions that how senior management makes the choices to manage its carbon emissions. Higher education provides an obvious example of applying this innovation.

CONCLUSIONS

There is a ongoing need to evaluate the process of SCM in the HE sector and to propose a clear routemap for integrating carbon management into the strategic management process. Some studies have already sought to analyze the carbon management issues within the organisations and have provided many insightful results and helpful recommendations. However it is surprising that empirical research examining the strategic approach and commitment to carbon management and strategic decision-making process within the HE organisations is relatively sparse. There is also a gap in the consideration of scope 3 emissions in the carbon management process because very few organisations are dealing with their supply chain emissions. This paper is part of a wider PhD study at DMU which aims to contribute to the debate by exploring the topic of strategic carbon management using DMU as a case study. Future research then will apply the case study research methodology to collect data using the relevant data collection tools and techniques. The evaluation and contribution to SCM knowledge in the HE sector will act as transferable best practices for other universities in an effort to lead to a breakthrough in the management of carbon through this novel strategic approach

AN EMPIRICAL INVESTIGATION OF STRATEGIC PLANNING IN QUANTITY SURVEYING PRACTICES

Dr. Róisín Murphy[1]

[1]*Lecturer, College of Engineering and Built Environment, School of Real Estate and Construction Economics, Dublin Institute of Technology, Bolton Street, Dublin 1, Ireland.*

ABSTRACT

The benefit of engaging in strategic planning has been well documented over several decades of strategic management research. Despite the significant body of existing knowledge in the field, there remains a limited collection of empirically tested research pertaining to strategic planning within professional service firms (PSFs) in construction, particularly from an Irish context. The research is an exploratory study involving in-depth, semi-structured interviews and a widespread survey of Quantity Surveying (QS) practices in Ireland. The aim of the research is to ascertain the extent of strategic planning undertaken within Irish QS practices, and to gain an insight into the characteristics of the strategic planning process therein. The findings show that the strategic planning process varies within QS practices and is correlated to practice size and ownership structure. Despite the absence of a systematic process in smaller QS practices, evidence suggests that principals are thinking and acting strategically. They confirm that a more systematic strategic planning process is beginning to emerge, particularly in light of the severity of the current economic and construction sector downturn in Ireland. This paper draws on existing literature in the field, as well as research findings to propose a strategic planning process model for PSFs within construction.

Keywords: professional service firms, strategic planning, quantity surveying.

INTRODUCTION

Strategic planning is a long established function in business yet there remains limited empirical evidence to determine the process by which construction firms engage in systematic strategic planning. The limited research that has been undertaken in construction has been heavily biased in favour of large contracting firms (Hillebrandt and Cannon, 1994) and there remains a dearth of empirical evidence regarding professional service firms (PSF) operating within the industry. The extent to which strategic planning processes proposed within the general strategic planning arena are applicable to QS practices, thus remains unconfirmed. This is particularly pronounced when considered within an Irish context.

The Irish construction industry has undergone monumental change over the last decade from the peak in 2006 when construction accounted for almost 25% of GNP and 13% of total employment, to current levels of 7% and 6% respectively (DKM, 2012). Government capital expenditure, low interest rates, relaxed lending criteria and

[1] Roisin.murphy@dit.ie

a deficit in housing stock were amongst the drivers that fuelled a construction boom of unprecedented proportion. The global financial crises, market uncertainty and rising national debt ultimately resulted in a bailout package from the IMF and EU worth €67.5bn and austerity measures that continue to stifle economic growth and investment in construction.

The importance of the construction industry to the Irish economy and the magnitude of the reversal of fortunes of the industry mean that now, more than ever, QS practices must engage in strategic planning to survive. This research paper addresses the perceptible gap in existing knowledge on strategic planning in QS practices in Ireland. Furthermore, it provides a framework for strategic planning in PSFs within the construction industry.

LITERATURE REVIEW

Strategic Planning

Strategic planning has been a prominent feature of strategic management theory over a prolonged period of time. The organisational benefits of engaging in strategic planning, (such as improved financial performance and increased market share) have been well documented (Brews & Purohit 2007); despite the fact that no single definition of strategic planning exists. Strategic planning is often associated with the alignment of objectives with organisational competencies in pursuit of competitive advantage. The dynamic nature of strategic planning and its varied application from one organisation to the next results in differing process characteristics between firms.

The strategic planning process is multifaceted and requires consideration of a number of variables including:

- the ***formality*** of the strategic plan as well as the formality of the process
- planning ***time horizon***
- the ***approach*** to strategy: planned, emergent or resource based (Mintzberg, 2003)
- ***organisational type***: prospector, analyser, defender, reactor (Miles & Snow, 1978)
- the ***industry environment*** within which the firm is operating (Grant, 2003).

Furthermore, characteristics of the process itself should be considered, including dimensions such as:

- ***strategic planning comprehensiveness***: the exhaustiveness of information gathering in informing decision making (Fredrickson & Mitchell, 1984)
- the extent of ***participation*** in the process across levels of the organisation (Dyson & Foster, 1982)
- the ***flow*** of initiatives – be it top down or bottom up
- the use of ***strategic planning tools***

Given the complexity of the process, the use of strategic planning process models is commonplace to provide a framework within which to consider the numerous variables. Several strategic planning models have been developed, which outline the need to determine organisational objectives and analyse the environment within which the firm is operating prior to a generic strategy being chosen (Porter, 1980). Firms

operating within a turbulent environment in particular, must ensure that the resulting strategy and strategic plan has sufficient flexibility to enable the firm to respond to the changing requirements of the industry within which they are competing (Grant, 2003). Once again, seldom have existing models been empirically tested on the construction industry, not least PSFs within it.

Strategic Planning in Quantity Surveying (QS) Practices

Strategic planning research in construction is heavily weighted towards contracting organisations (Betts and Ofori, 1992; Dansoh, 2005) rather than the professions, including QS practices (Jennings and Betts, 1996). Additionally, significant emphasis is placed on project planning and management within construction rather than organisational or strategic planning (Phua, 2006). However a longitudinal study undertaken by Boon (2008) on QS practices in New Zealand (reported within this forum), has provided some insight into the management of a small number of QS practices in New Zealand, along dimensions of market orientation, knowledge base, cost structure, price competitiveness and financial resources.

Limited as construction strategic planning research is, there are opposing views regarding the prevalence of strategic planning within the industry. On the one hand Betts and Offori (1992) suggest there is a "*dominant structural shift in the emphasis of business planning from the tactical to the strategic*" (pp. 513) whereas Hillebrandt and Cannon (1994) argue that there is a lack of strategic planning in construction firms in the UK because it is not necessary to plan for large investments in fixed assets. Until now, this has not been confirmed within an Irish context.

RESEARCH METHODOLOGY

The research reported forms part of a wider investigation of strategic planning within Irish QS practices, and was undertaken in two stages.

Stage 1:

Semi-structured interviews were conducted with the Managing Director/Partner within ten QS practices. A selective sample based on known information pertaining to company size was used to ensure practices of varying sizes were included in the sample.

Interview questions were developed (and pilot tested) in advance of the interviews addressing the key dimensions and characteristics of the strategic planning process identified in the literature. Table 1 presents an overview of the main topics addressed.

Table 1 Questionnaire Content

***Questionnaire section h*eading**	***Issues addressed within section***
General Company Information	Position held by respondent, ownership structure, sectors serviced, services provided, number of employees
Generic Strategy	Strategic type, approach, environmental analysis, corporate and business strategy
Strategic Planning Characteristics	Formality, written plan, participation, flow, planning time horizon, content, constraints on the strategic planning process

The semi-structured interviews allowed flexibility in the sequence of questions and depth of discussion of pertinent issues raised. The initial stage provided a considerable insight into the strategic planning processes of the practices, and also served to inform the second stage of research.

Stage 2:

A small research grant was made available by the Society of Chartered Surveyors Ireland (SCSI) to undertake a widespread investigation of strategic planning within members of the QS Division of the Society. Questions were informed by an extensive literature review and by insights gained in stage one. The questionnaire contained similar headings to those outlined in Table 1. The final sample size was 150 and a response rate of 41% was achieved. Phase one participants were involved in the second phase, and are included in the total above. This served to triangulate findings from the initial stage.

FINDINGS AND ANALYSIS

General Company Information

Demographic information on participating firms was confirmed as follows:

- 85% of practices are independently owned. The remainder are part of an international organisation
- 79% have been operational over 5 years; with 66% over 10 years
- 66% have five or fewer employees, with only 1 respondent having greater than 100 (these figures were 41% and 2 respectively at peak, 2007)
- 39% are ISO certified

Strategic Planning Characteristics

The overwhelming majority of QS practices do not have a formal strategic planning process, nor do they have a written strategic plan, which differs from the findings of, for example, Dansoh (2005) within QS practices in Ghana. Of the third that do have a formal process and written plan, the practice is part of a larger construction

consultancy group and has a time horizon of 3 years, which concurs with Dansoh (2005) findings. The approach to strategy is planned, involves considerable analysis of the internal and external environment and participation of staff at various levels within the organisation is apparent. The strategic planning process across the majority of respondent practices is however, unstructured and undocumented, with a top down flow and limited participation, which is similar to conclusions drawn by Price et al. (2003) within the UK construction sector.

Regardless of the existence of a formal plan, internal organisation, industry and economic analysis are prevalent while a notable lack of competitor analysis is undertaken across the board. While this represents a divergence from the general strategic planning literature, it corresponds with the findings of Price et al. (2003). Limited information pertaining to competitor behaviour, and a concentration on the client (rather than competition), may go some way to explaining the divergence. The importance of client retention and repeat business cannot be over stated in the context of PSFs, as noted by Maister (2003) when he puts forward that:

> "*Most professional firms say that their existing clients represent the most probable (and often the most profitable) source of new business*." (pp.97)

Without exception, respondents stressed the importance and reliance upon repeat business which coincides with the above observation. Furthermore, emphasis is placed on the internal capabilities and competencies of the practice to ensure that the practice reputation affords the opportunity of securing repeat business, as well as referral business (through word of mouth). This forms a crucial component of the strategic decision making process within QS practices, which concurs with the findings within PSFs across other sectors (Maister, 2005).

As regards generic strategy being pursued, the overriding strategy amongst QS practices is currently stability (or survival). Significant proportions are pursing a combination strategy of domestic stability together with international expansion. The exceptional economic and industry environment conditions must be borne in mind when considering this finding, which could usefully be revisited periodically to gain deeper insight. Many practices had already retrenched when fieldwork for the research was undertaken therefore it was noted in the minority of cases.

Patterns in the strategic planning process amongst respondents reveal that strategic planning process characteristics differ between QS practices depending on size and ownership structure. Practices that are subsidiaries of larger international construction organisations tend to have a formal, structured process for strategy development driven primarily by head office requirements. The positive relationship between practice size and strategic formality has previously been noted within the construction sector in the UK (Price et al., 2003) and Ghana (Dansoh, 2005). Indigenous practices, on the other hand, currently tend to have an informal/ad hoc approach to strategic decision making, which is driven by the principal and seldom results in a written plan.

The turbulent economic and industry environment has resulted in increasing industry, economic and internal analysis being undertaken. However, as noted by Hillebrandt and Cannon (1994) in UK construction firms, evidence within Irish QS practices indicates that principals are thinking and acting strategically, but not necessarily in a

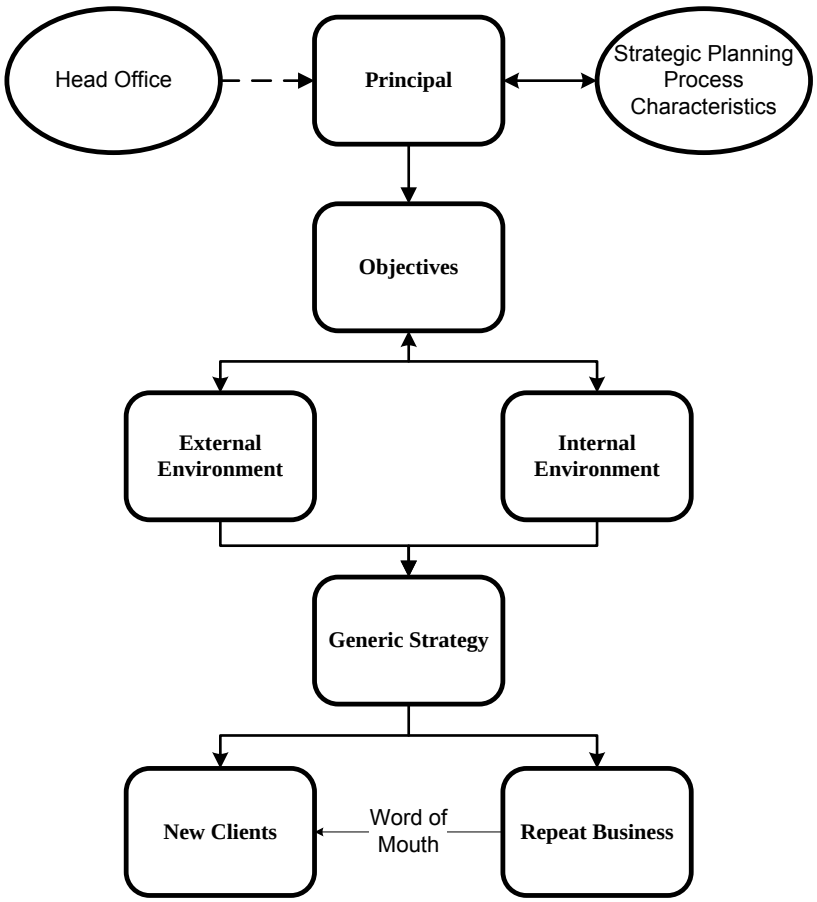
systematic way. Crucially however, nearly half of the respondents currently without a systematic strategic planning process (hence plan), noted that strategic planning processes are beginning to emerge.

The research reported confirms that strategic planning is being successfully implemented in QS practices, most notably those that form part of an international construction organisation. Within these practices there is a convergence with the strategic planning literature as regards formality, approach, participation and the use of strategic planning tools to facilitate the process but a divergence is evident in the lack of competitor analysis undertaken. However, practices that systematically engage in the process tend to be large firms, which constitute the minority of QS practices in Ireland. Given the growing recognition of the need to engage in strategic planning, particularly in light of uncertainty and intense competition within the sector, an opportunity now exists to model the process for more widespread application.

Modelling Strategic Planning for QS Practices

The strategic planning process will not be identical in every organisation. The multifarious nature of the process thus warrants the use of a model to act as a framework of analysis of existing strategic planning practices, and guide the formulation of a new strategic plan. Resulting from the empirical investigation reported, a model of strategic planning was developed and is presented in figure 1.

Figure 1: Strategic Planning Process Model



Strategic planning in QS practices is primarily driven by the principal, save for subsidiary organisations, where initiatives are driven by head office. The approach and strategic type play a critical role in this regard in determining process characteristics such as process formality, plan formality, scope of participation, planning time horizon and use of strategic planning tools. Head office and process characteristics vary between groups and are important influences in shaping the process. Other components of the model are applicable across all practices, regardless of formality of the process or existence of a written plan.

Organisational objectives are developed based on the internal environment and competencies (staff, marketing, finance, IT, quality) as well as the external environment (macroeconomy, construction sector, professional body standards) prior to the determination of the generic strategy in pursuit of objectives. In quest of competitive advantage, the generic strategy signifies the mechanism by which new clients will be sought and also how new business is generated with existing clients. Within PSFs, and specifically QS practices, a major source of new client business is achieved through word of mouth, thus the reputation of the practice is crucial in pursuit of competitive advantage. The dynamic nature of construction is such that the external and internal environments must be constantly monitored thus a two way flow between organisational objectives and environmental analysis is evident.

CONCLUSIONS

The results of this study demonstrate that Irish QS practice principals are thinking and acting strategically, yet often no systematic strategic planning process is evident. With the severity of the economic and construction industry crises, increased competition and demanding clients, the need for systematic strategic planning has never been more critical. Recognition of the role of strategic planning in QS practices is emerging.

The multi-faceted nature of strategic planning results in a complex process which is exacerbated in the context of a turbulent environment such as the construction sector. The process does not, however, need to be cumbersome or rigid, nor does it require the recruitment of external consultants. Strategic planning must be systematic, participative, ongoing and realistic, yet remain flexible to allow for changes within the industry and competitive environment. The use of the model presented may act as a framework within which to consider the components of the process. Participation from staff is crucial for idea generation, as well as instilling a sense of ownership of the strategy. This is particularly important for PSFs, whereby staff interaction with clients cultivates the reputation upon which repeat business depends. The education and training of a QS in project and risk management must now be transferred from the tactical (project level) to the strategic, in order to better position QS practices for recovery.

AUSTRALIAN CARBON CALCULATOR INITIATIVES: FUEL CONSUMPTION AS A PROXY FOR MASS-HAUL GREENHOUSE GAS EMISSION DURING ROAD CONSTRUCTION

Su Yin Tan[1], Toby Harfield[2], Russell Kenley[3] and Payam Pirzadeh[4]

[1234]*Faculty of Business and Enterprise, Swinburne University of Technology, PO Box 218, Hawthorn, 3122 Australia*

ABSTRACT

Australian state transport authorities are required to support Australian Kyoto Protocol commitments through investment in methods of reducing greenhouse gas emissions. Most states have involved themselves in development of carbon calculators to be used in all phases of road construction, operations and maintenance. The initiatives include the Greenhouse Gas Assessment Workbook developed by a group of transport authorities an extension of the Workbook, Carbon Gage developed by VicRoads. Analysis of the calculators provides evidence of an unarticulated general acceptance of fuel consumption as a proxy for emissions. At the same time analysing the Australian and international carbon calculators for specific and detailed mass-haul parameters illustrates the uncertainty concerning the accuracy of calculator methodologies and measures produced to-date.

Keywords: Australia, GHGE proxy, carbon calculator, fuel consumption, mass-haul.

INTRODUCTION

As part of its commitment to the Kyoto Protocol, Australia plans to reduce greenhouse gas emissions (GHGE) by at least 5% below 2000 levels by 2020. Construction of infrastructure has been identified as a major contributor of GHGE and government transport agencies at all levels have invested in development of reduction options. Although much research has been conducted concerning vehicle travel on completed roads, little research has focused on negative environmental impacts during construction. The balance of this paper reports on the initial stages of an Australian multi-stage research project studying the effects of mass-haul GHGE during infrastructure construction. This report is based on a desktop search of Australian government documents, international GHGE inventory reports, global emissions

[2] tharfield@swin.edu.au
[3] rkenley@swin.edu.au
[4] ppirzadeh@swin.edu.au

calculators related to infrastructure construction and a range of relevant academic literatures on mass-haul in relation to a sustainable built environment.

All states in Australia are designing processes to support the Commonwealth government commitment to reduce GHGE. One specific area of progress is for infrastructure construction. The total value of road construction in Australia for 2010-11financial year was $AU16.2 billion, comprised of $AU5.2 billion from the private sector and $AU11 billion from the public sector (Australian Bureau of Statistics 2012). The six state government transport authorities have the responsibility for building major roads. These transport authorities also have oversight of environmental impacts during both the construction and the operation phases of transportation systems. Currently, the two most populated states, Victoria and New South Wales (NSW), have progressed from developing sustainability policy to the development of tools and processes to assist in the reduction of GHGE during infrastructure construction.

Victoria appears to be the most advanced Australian state in translating greenhouse reduction policies into action. The state transport authority, VicRoads, introduced a voluntary sustainability rating tool, INVEST (Integrated VicRoads Environmental Sustainability Tool) in March 2011. Greenhouse gas monitoring of road construction activities is one of the prerequisites to participating in the INVEST rating program, whereby the contractor must have a system for recording site use of fuel, quantities and types of materials, energy and waste generated. The collected data is then used to calculate a greenhouse gas footprint of the road construction project (VicRoads 2011). In order to quantify GHGE, VicRoads has also developed a spreadsheet based calculator called Carbon Gauge, which calculates the whole-of-life environmental impacts for road construction, operation and maintenance.

In alignment with the NSW Government Sustainability Policy, NSW Roads and Maritime Services has a commitment to becoming carbon neutral by 2020. This goal takes into account current road life-cycle estimates of CO_2e. Road construction is projected to generate approximately 461,000 tonnes of CO_2e for the 2012-13 period, while maintenance activities are projected to produce 256,000 tonnes of CO_2e for the same period Operation activities are estimated to produce 165,000 tonnes of CO_2e per year from November 2011 onwards (NSW Roads and Maritime Services 2011).

If these estimates are accurate, it would mean that construction of roads, not road operation and maintenance, would account for the majority (52%) of emissions. In terms of reducing greenhouse gas emissions from mass haul operations, NSW and South Australia are process leaders. Currently, these two states also require earthworks plans to be submitted as part of the tendering process for major construction. This mandatory requirement promotes the planning of efficient, feasible and optimised mass-haul which would result in lower GHGE due to a reduced consumption of fuel.

GREENHOUSE GAS EMISSIONS

In general, emissions are calculated using emission factors (EFs) and associated activity (A) information. Emission factors indicate the mass of pollutant emissions released per unit of the associated process variable. Activity information refers to the process variable, such as mass of fuel consumed or output produced. The emissions (E) are then calculated as:

$$E = EF \times A \quad \text{(Miller et al. 2006)}$$

 ISBN: 978-1-84219-840-7 .

The three greenhouse gases which are relevant to fuel combustion are carbon dioxide (CO_2), nitrous oxide (N_2O) and methane (CH_4). According to the IPCC, CO_2 emission factors for fuels are generally well determined within ±5%, as they are primarily dependent on the carbon content of the fuel. As for non-CO_2 emissions, however, the uncertainty of the CH_4 emission factor may be as a high as a factor of two while the uncertainty of the N_2O emission factor may be an order of magnitude, i.e. a factor of 10 (IPCC 2000). Methane (CH_4) emissions in petrol and diesel vehicles vary with the use of catalytic converters. The use of post-combustion control reduces methane emissions. Nitrous oxide (N_2O) emissions from motor vehicles arise primarily as a result of catalysts in road vehicles, as N_2O emissions are a by-product of the catalysts' removal of oxides of nitrogen (NO_x) (Beer et al. 2002).

According to Caterpillar suppliers in Australia, most earthmoving vehicles available in the Australian market do not have catalytic control devices installed, but some machines are now starting to be supplied with Tier 4 emission control devices. Tier 4 emission standards were introduced by the US EPA in 2004 (to be phased in during 2008-2015), and require the emissions of particulate matter and NO_x from non-road engines to be reduced by 90%. The US EPA also introduced regulations on sulphur content (15ppm) in non-road diesel fuels to enable sulphur-sensitive catalytic control technologies for Tier 4 (Dieselnet 2012). However, even with computerised vehicles able to provide accurate consumption of fuel, calculating emissions is not without problems. Uncertainty in the calculated emissions can be classified as scientific uncertainty (for example, uncertainty in Global Warming Potentials), model uncertainty (associated with the mathematical equations used to characterize the relationships between various parameters and emission processes), or parameter uncertainty (associated with quantifying the parameters used as inputs, e.g. activity data, emission factors, or other parameters) (World Resources Institute 2003). However levels of uncertainty have not deterred governments and industry from cooperating in the development of tools and methodologies to reduce the negative environmental impact of GHGE created during the construction of major works.

GREENHOUSE GAS CALCULATORS FOR MASS-HAUL

Construction of roads is usually considered as a 'macro process' in discussions related to environmental impact. However, if the estimate by RMS that over half of future carbon dioxide emissions (CO_2e) will be generated during the construction phase is accurate, then a closer consideration of the construction process could provide new methods of reducing total GHGE. One road construction 'micro-process', earthworks or mass-haul operations, has been identified as an area which has significant potential for the reduction of GHGE (Kenley et al. 2011). Earthworks are a significant part of major road projects, accounting for as much as 35% of the total construction cost according to industry sources. Haulage of soil and rock from cut to fill sites results in GHGE from the combustion of diesel, which can be highly variable depending on the efficiency of contractor practices. Thus, concentrating on the emissions from the fuel used during construction specifically related to earthworks could provide an opportunity for reducing total GHGE.

Governmental support for Kyoto has produced a global search of methods to reduce greenhouse gases. This desktop search has found a number of different types of 'carbon calculator' that include mass-haul activities. The early form appeared as spreadsheets, such as the Roadway Construction Emissions Model (2009) developed by Sacramento Metropolitan Air Quality Management District and the Environment

Agency's Carbon Calculator for Construction Activities (2007 & 2010) designed and improved by the Environment Agency, UK.

The second round of development has resulted in software options. Table 1 provides a sample of currently available internationally developed software that can be used for GHGE calculations in relation to earthworks/mass-haul. The earthwork parameters vary but mostly include fleet information, scheduling data and a mixture of on-site and off-site haulage information. The functionality claimed of course depends on user capability. As would be expected the products use data from previous projects to generate estimated future emissions. Data sources are location specific which may mean that a universal tool is not as effective as one developed taking into account local conditions. (Two other software products have been mentioned in relation to

GHGE calculation and mass-haul but no internet presence was found for JouleSave a plugin for MXROAD and Arup CO2ST Tool).

The Australian Contribution

Agreeing on standardisation of greenhouse gas calculations amongst countries, states or industries is problematic. It is a difficult task to define boundaries and agree on parameters for calculations to ensure fair comparison when local laws, practices and environmental limitation must be taken into account. Daviet (2006) notes the most important step in designing an industry-specific tool for calculating GHGE is to engage stakeholders in a transparent and inclusive approach. The argument for engagement is that stakeholders involved in the development of a tool or methodology are more likely to champion adoption. This approach assisted the Australia and New Zealand Transport Authorities Greenhouse Group (TAGG) in the development of a standard greenhouse gas calculation method for road projects in both countries. Joining New Zealand, the Australian member states include: Victoria, New South Wales, South Australia, Western Australia and Tasmania (one state and the two territories are absent from the group).

TAGG published the Greenhouse Gas Assessment Workbook for Road Projects in June 2011 (Dilger et al. 2011b). The Workbook contains quantification methods designed to be compatible with the Greenhouse Gas Protocol Corporate Standard, consistent with methods recommended by IPCC (2000) for the compilation of emissions at the national level. The standard is linked to the six greenhouse gases named in the Kyoto Protocol: carbon dioxide (CO_2), methane (CH_4), nitrous oxide (N_2O), hydrofluorocarbons (HFCs), perfluorocarbons (PFCs), and sulphur hexafluoride (SF_6). The link to the international movement for consideration of climate change is important for meeting Kyoto targets nationally although, the TAGG Workbook authors indicate "road projects will typically only result in emissions of carbon dioxide". The Workbook is considered to be both a means of calculating estimated GHGE and learning how these emissions could be reduced. In addition, the Workbook is expected to support comparison of projects to develop benchmarking greenhouse gas reduction best practice between Australia and New Zealand projects.

The TAGG Workbook methodology currently involves the use of default quantity factors which are assumed values for project variables. These construction project variables are specifically related to earthwork and fuel usage, e.g. default quantity factors listed in the Workbook include: cut to fill diesel use of 1 L per m^3, cut to spoil diesel use of 4 L per m^3, import and placement of fill diesel use of 3.5 L per m^3, and strip and respread of topsoil diesel use of 1.2 L per m^3. In the absence of material quantities, the default quantity factors to be used would be: grader fuel use of 5.1 kL per month, wheeled loader fuel use of 4.5 kL per month, and scraper fuel use of 14.5 kL per month (Dilger et al. 2011b). The majority of the default quantity factors were extracted from the Greenhouse Gas Assessment Tool developed by the South Australian Department of Transport, Energy and Infrastructure for use by cost estimators, including default quantity factors for demolition and earthworks (Dilger et al. 2011a). The Carbon Gauge greenhouse gas calculation tool developed for VicRoads is based on the TAGG methodology, and contains the same default quantity factors for the calculation of emissions. These assumptions for fuel consumption values per unit of material to be moved are used within the calculator without explicitly stating the haul distances or other conditions for which they are appropriate.

 ISBN: 978-1-84219-840-7 .

FUEL CONSUMPTION AS A PROXY FOR GHGE

Hughes et al. (2011) claim that there are two approaches to calculation of CO_2e for mass-haul during linear infrastructure construction. They suggest that the current 'top-down' practice of using pre-determined coefficients based on a database of historical data (Hammond and Jones 2008) could provide inaccurate and potentially costly estimates. They suggest using a 'bottom-up' approach that provides a project specific assessment of fleet and quantities based on site specifications. The bottom-up approach estimates the number of hours of equipment use from the amount of material to be moved. The hours of equipment use are converted to fuel consumption and fuel consumption is used to calculate the associated emissions. According to Hughes et al. (2011), standardised carbon dioxide values for earthworks operations are frequently not representative and calculating based on specific project variables such as ground conditions, haulage distances and quantities provides more accurate mass-haul CO_2e.

Regardless of the methodology used to calculate GHGE for mass-haul or the accuracy of such estimates, all calculators appear to agree that the use of fuel consumption data (or an estimate of fuel consumption) in earthworks operations is the most direct, robust, convenient and economical method available for calculating emissions because:

1. **GHGE are highly proportional to the amount of fuel combusted** as the majority of the emissions are CO_2e formed from the combustion of carbon contained within the fuel, while N_2O emissions which usually arise from oxidation of NO_x are not as prevalent in earthmoving vehicles in Australia. The majority of Australian earthmoving equipment is not equipped with oxidation catalysts resulting in nitrous oxide emissions through oxidation of NO_x. CH_4 emissions form a relatively small component of total emissions (in terms of CO_2 equivalents).
2. **Using fuel consumption data does not require additional measuring devices** which may be too expensive to be installed and maintained on a wide-scale basis.
3. **Fuel consumption data is convenient to collect** as it is usually available through invoices.
4. **Other methods of estimating emissions rely on engine specific data or statistical data** that would not be applicable to Australian vehicles, and would therefore be inaccurate.

CONCLUSION

Australian state transport authorities are part of a global effort to reduce greenhouse gas emissions. The results of this engagement are the TAGG Workbook to reduce project GHGE and the whole-life products, INVEST and Carbone Gage developed by VicRoads. This paper provides a first report of a major Australian study concerned with developing a methodology for reducing greenhouse gas emission from mass-haul activities during infrastructure construction (Kenley et al. 2011). The initial desktop document analysis and exploration of international carbon calculators has provided verification that measuring greenhouse gas emission is complex and difficult to standardise. The range of public and private carbon calculators that have been developed provides evidence of the extensive number of factors which affect calculation of negative environmental emissions. Whether or not calculations are considered for the total lifecycle of road construction or focused on the micro-process of mass-haul during construction the complexity of activities, fleet, and materials

means that measurement methodologies are still at the incubation stage. Therefore all present attempts of calculating actual GHGE will for the present need to rely on using fuel consumption as a proxy for GHGE despite uncertainty concerning the accuracy of these figures.

CARBON REVIEW AND QUALITATIVE COMPARISON OF SELECTED CARBON COUNTING TOOLS

Damilola Ekundayo[1], Srinath Perera[2], Chika Udeaja[3] and Lei Zhou[4]

[1,2,3,4] *School of the Built and Natural Environment, Northumbria University, Newcastle upon Tyne, NE1 8ST, UK*

ABSTRACT

Climate change is one of the greatest environmental threats facing our civilization today. In the UK, carbon related to buildings amount to around half of the total greenhouse gas emissions. It is essential that we are able to accurately count carbon which is now increasingly being used as a metric of building environmental performance and energy efficiency. Following the rule that only measurable is manageable, quantifying carbon will serve as a basis for building environmental management and improvement. The aim of this paper is thus to review the concept of whole-life carbon in buildings and the different carbon estimating tools available. The research revealed that the total (whole-life) carbon emissions associated with a building from cradle-to-grave can be categorised into embodied and operational carbon. Whilst there are now formalised methods for measuring operational carbon due to its significance in whole-life carbon, there is still less emphasis on embodied carbon counting despite the rising need and importance. Qualitative comparison of some selected open source UK tools for embodied carbon estimation shows disparities in boundary definitions, unit of measurements and methodological calculations amongst others. These suggest that an industry agreed data structure and common methodology is needed for embodied carbon estimation.

Keywords: building environmental performance, carbon counting tools, climate change, embodied and operational carbon, greenhouse gases.

INTRODUCTION

Climate change is one of the greatest environmental threats facing our civilization today (Ürge-Vorsatz & Novikova, 2008; Kenny *et al.*, 2010). Carbon related to buildings amount to around 47% of the total greenhouse gas emissions causing climate change in the UK (BIS, 2010). It is essential that we are able to accurately count carbon which is one of the worst contributors to these greenhouse gases to reduce the devastating impact of the increasing concentration of greenhouse gas emissions on the environment (Grant *et al.*, 2009). The design process can greatly benefit from accurate carbon counting as it will reveal the carbon implications in units of the various design options and decisions made at the early stages of a development.

[2] srinath.perera@northumbria.ac.uk
[3] chika.udeaja@northumbria.ac.uk
[4] lei.zhou@northumbria.ac.uk

This will in turn help to maximise potential for reduction and facilitate opportunities for environmental improvement (Lowe, 2000; Atkinson *et al.*, 2009).

Carbon emissions are now being used as a benchmark for building environmental performance in the UK construction industry (Hammond & Jones, 2008a; Anderson *et al.*, 2009) and in direct response to the Energy Performance in Buildings Directive, 2002 and current UK Building regulations Approved Document Part L, 2006 (BIS, 2010). Similarly, around the world particularly in advanced economies, carbon is increasingly seen as a metric of environmental performance and energy efficiency (Pandey *et al.*, 2010; Mah *et al.*, 2011; RS Means, 2011). Carbon taxation, carbon reduction commitments and off-setting continue to propel the increasing significance of counting carbon. For example, the EU Emissions Trading Scheme (ETS) was founded to regulate carbon emissions, and the UK power prices now include carbon component (Voorspools, 2006). It thus means that carbon emissions now have monetary cost attached to its environmental implications and this is changing the culture in the industry towards environmental awareness and carbon accountability.

With the invention of the Climate Change Act 2008, it is now a legal obligation in the UK to reduce carbon and different targets have been set to enhance this commitment. Compared with the 1990 baseline, 26% reduction is expected by 2020 and no less than 80% by 2050 according to the recent government reports (DECC *et al.*, 2008; BIS, 2010). This obligation continues to be driven by the UK Government, EU regulations and corporate social responsibility in the private sector (BIS, 2010). Specifically, in the UK, a range of tax, levy, incentives and market mechanisms have been put in place to support this obligatory commitment of reducing carbon and other greenhouse gases (Pellegrini-Masini *et al.*, 2010; Monahan & Powell, 2011).

To combat climate change, carbon accountability and management will serve as a basis for building environmental performance and can help to promote environmental aware buildings (Pandey *et al.*, 2010; Mah *et al.*, 2011). To evaluate the environmental implications of a product the carbon impact resulting from each stage of its life cycle must be accounted for (Hammond & Jones, 2008a). Carbon counting can help to determine what and where significant carbon emissions are being produced during the life cycle of an asset to enable appropriate mitigating measures in a cost effective way at the initial phases of the design process (Sturgis & Roberts, 2010). Consequently, there have been several attempts globally to develop tools for quantifying these carbon emissions. The aim of this paper is to review whole-life carbon emissions associated with a building and the currently available carbon estimating tools. It further explores the consistency of selected open source UK embodied carbon counting tools using a qualitative comparison.

WHOLE-LIFE BUILDING CARBON FOOTPRINT

Different authors have diverse views of what whole-life carbon represents. Pandey *et al*. (2010) are of the opinion that the carbon footprint of a product throughout its life-cycle includes the carbon content from manufacture through to distribution, consumption/use and disposal. The carbon footprint associated with the different stages of a product entire life-cycle otherwise known as cradle-to-grave can either be direct or embodied emissions (Pandey *et al.*, 2010). Roche & Campanella (2010) simply refers to the carbon content associated with a product from cradle-to-grave as carbon emissions. The UK Building Cost Blackbook classified carbon footprint as either embodied or direct carbon (Franklin and Andrews, 2010) whilst embodied and operational carbon were the terms used by Hammond & Jones (2008a).

Indeed, the use of the terms may be different from one author to the other but it appears that the fundamental principles remain the same. Sturgis & Roberts (2010) gave a definitive explanation of carbon footprint associated with a building life cycle. They stated categorically that the total (whole-life) carbon emissions in a building include both embodied and operational carbon. Notably, several other research in this field agree with this classification and concept (Shipworth, 2002; Hammond & Jones, 2008b; Anderson *et al.*, 2009; Pandey *et al.*, 2010). The subsequent sections explain the operational and embodied carbon emissions associated with a building life cycle.

Operational carbon

Operational carbon emissions which are the emissions generated from the activities of the building users as a result of lighting, electricity, heating and cooling contribute a staggering 70% to the total carbon emissions associated with a building (BIS, 2010; Sturgis & Roberts, 2010).. There have been considerable measures taken by the industry, government and even individuals to reduce these emissions. The UK government on their part has developed legislation such as Part L of the Building Regulations and the quantification of operational carbon emissions of buildings is now achieved by various standard assessment methods such as Energy Performance Certificates (EPCs) and Display Energy Certificate (DECs) (Sturgis & Roberts, 2010).

In different parts of the world, there are standard published sources available that provide the emission factors for each energy supply for converting the operational energy usage in a building into carbon emissions (Pandey *et al.*, 2010). The actual total energy usage of an existing building can be read from a meter whilst for a proposed building, different energy modelling software such as HEED (Home Energy Efficient Design), Design Builder, etc. are available in the industry for deriving an estimate (Roche & Campanella, 2010). Carbon emissions resulting from operational energy usage in UK buildings can be calculated using the emission factors indicated in DEC methodology published by DEFRA (BIS, 2010). Also, there are many carbon footprint calculators being developed in the industry for this purpose and to raise environmental awareness such as Act on CO2, Carbon footprint calculators, etc.

Embodied carbon

Embodied carbon emissions contribute approximately 30% of total carbon emissions from buildings over its entire life although it could be more or less depending on building types (BIS, 2010). Embodied carbon measurement has not received sufficient attention in terms of government legislation and currently has no standard assessment methodology (Sturgis & Roberts, 2010). Hammond & Jones (2008b) defined embodied carbon of building materials as the total carbon released over its life-cycle. According to Franklin and Andrews (2010) it is the total carbon emissions as a result of total primary energy consumed during the life-time of a product. It thus implies that the embodied carbon associated with a building can be categorised into various boundaries. Interestingly, there is a common agreement in the industry as to the definition of these boundaries in respect of embodied carbon calculation (Hammond & Jones, 2008a, 2008b; Anderson *et al.*, 2009; Franklin and Andrews, 2010). The system boundaries of a product, which is the point in the product life-cycle (or life-time) that embodied carbon could be counted, are analysed below.

Cradle-to-Gate (all carbon emitted or released until the product leaves the factory gate); **Cradle-to-Site** (includes all carbon emitted until the product has reached the point of use which is the building site); **Cradle-to-End of construction** (carbon emitted

in cradle-to-site plus emissions as a result of assembly on site and construction activities); **Cradle-to-Grave** (all carbon emitted from the extraction of raw materials until the end of the products lifetime including maintenance and final disposal); **Cradle-to-Cradle** (applies only to recycled materials as it also includes element of recycling). This last is not yet a commonly used system boundary due to the many complications and uncertainties with recycled materials (Hammond & Jones, 2008b).

CARBON COUNTING TOOLS

Carbon counting is quantifying in units the carbon impact of a product. The carbon footprint of a building over its life-cycle is divided mainly into two phases namely construction phase and operational phase (Sturgis & Roberts, 2010). Fieldson *et al.* (2009) concluded that there are many carbon counting tools available in the market but most of them are not suitable for providing the level of carbon information details required in construction. Whilst most carbon counting tools offer the possibility for determining carbon emissions as a result of operational energy use in a building and from transportation, fewer tools can provide embodied carbon emissions associated with construction processes and activities (Roche & Campanella, 2010). Roche & Campanella (2010) suggested that carbon counting tools can be divided into different classifications based on the type of carbon information they provide. These carbon counting tools and the type of information they produce are discussed below under the two classifications commonly referred to by the various authors in this area.

Firstly, carbon footprint calculators are mostly freely available online to determine personal carbon emissions from home like electricity and gas usage, food, water, waste, transportation and the likes. There are countless example of these tools available worldwide and they include: Liveclimate, American Forests, Greenhouse gas calculator, Best Foot Forward, BP calculator, California Carbon calculator, Chuck Wright, Clear Water, EPA Personal Emissions calculator, Safeclimate, etc. Some of these tools even provide opportunity to buy carbon offsets, which involves investing in renewable technologies to balance energy usage (Pandey *et al.*, 2010). The reliability of these carbon footprint calculators is however questionable as most of them will produce different results with similar inputs (Roche & Campanella, 2010).

Secondly, carbon estimators and calculators are for estimating embodied carbon emissions in buildings such as carbon emissions associated with construction processes and building maintenance (Hammond & Jones, 2008b; Jones, 2009). They are seldom freely available online (Mah *et al.*, 2011). Many of the carbon estimators and calculators currently available in the industry are mostly for in-house use (Roche & Campanella, 2010). Examples of carbon estimators include Build Carbon Neutral Construction Calculator, Athena: EcoCalculator for Assemblies, Construction carbon calculator, etc. Examples of publicly available carbon estimators and calculators in the UK include CapIT and UK Building Blackbook (Franklin and Andrews, 2010), BRE Green Guide (Anderson *et al.*, 2009), Carbon Calculator for Construction Activities (Jones, 2009) and ICE Database (Hammond & Jones, 2008a, 2008b).

In the past, government and industry have given greater attention to operational carbon management with less emphasis on embodied carbon assessment (BIS, 2010). However, as legislations intensify on reducing operational carbon the relative importance of embodied carbon and the carbon embodied in products is on the rise due to lack of attention (Sturgis & Roberts, 2010; RICS, 2012). Hence it is vital to further investigate some of the stated tools, currently and publicly available in the UK, for embodied carbon counting of construction, for comparison purposes (see Table 1).

Table 1: Comparison of UK open source construction carbon counting tools

Tool	Comment	System Boundary
Inventory of Carbon and Energy (ICE) Version 2.0 ICE was developed at the University of Bath	**Calculates:** embodied CO_2 and/ or CO_2e of approximately 200 different building materials. **Unit of measurement:** $kgCO_2/kg$ and/ or $kgCO_2e/kg$ OR $kgCO_2/m^2$ and/ or $kgCO_2e/m^2$. **Generic conversion factor:** CO_2e is 6% higher than the CO_2 value based on UK fuel mixes. **Note:** ICE used to be the only open source, freely available peer-reviewed tool available for its purpose until recently. CO_2e = carbon equivalent or greenhouse gases.	Cradle-to-gate
Construction Carbon Calculator Developed by the UK Environmental Agency (EA) and Jacobs Engineering	**Calculates:** CO_2e (in tonnes) of construction activities (i.e. CO_2e of construction materials and the CO_2e associated with their transportation, site energy use and waste). **Unit of measurement:** CO_2e per tonne. **Note:** developed using CO_2e values derived from ICE database. The tool (an Excel spreadsheet) allows inclusion of materials not covered if their CO_2e per tonnage is known.	cradle-to-end of construction
The Green Guide Developed by the Building Research Establishment (BRE)	**Calculates:** CO_2e of more than 1500 specifications of building materials and components in terms of various building element sections and subcategories across a range of 6 different generic building types. **Unit of measurement:** $kgCO_2e/m^2$ (on an elemental uniform basis). **Note:** the Green Guide Calculator is an online bespoke tool that generates CO_2e values not listed in the Green Guide (available in hardcopy print and also as an online tool).	Cradle-to-grave (over a 60 year building life)
CapIT/ Blackbook (Capital Cost and Embodied CO_2 Guide) Developed by Economic and Research Unit of Franklin & Andrews (part of the Mott MacDonald group)	**Calculates:** embodied CO_2 values of construction work activities including direct emissions from plants usage on site and tools. **Unit of measurement:** $kgCO_2$ per standard methods of measurement (SMM) work item unit **Note:** developed using ICE database and other reliable sources. Elements of waste have been included in the CapIT carbon figures. The database for the tool was developed in accordance with SMM with an embodied carbon value for each work item. The Blackbook is the hardcopy version of CapIT (which is regularly updated).	Cradle-to-gate (plus site and construction activities) OR Cradle-to-end of construction (minus transport)

Table 2 Cont'd: Comparison of UK open source construction carbon counting tools

Tool	Limitation	Reference
Inventory of Carbon and Energy (ICE) Version 2.0	**Lower level info:** embodied CO_2 values for primary materials like gravel, etc. and secondary materials like bricks, etc. Hence a tedious option to calculate embodied carbon for entire building. **Detailed information:** such as drawings, materials and project specification required for ease of use. **Unit of measurement:** not consistent for all the materials in the database.	(Hammond & Jones, 2008a, 2008b). University of Bath ICE Database. Initially, it was made freely available via an online website as an Excel spreadsheet. http://www.bath.ac.uk/research/features/embodiedenergy.html
Construction Carbon Calculator	**Lower level info:** CO_2e values for basic materials and composite items only. Hence a tedious option for embodied carbon calculation of buildings. **Detailed information:** required. **Coastal and fluvial projects**: tool only covers some materials mostly common to this kind of work. **Limited CO_2e data:** for building projects.	(Jones, 2009). EA Carbon Calculator. Freely available online as an Excel spreadsheet for public usage. http://www.environment-agency.gov.uk/business/sectors/37543.aspx
The Green Guide	**Carbon information source:** has been largely developed based on estimation. **Extent of information:** not all building elements and building element material specifications are covered. **System boundaries: a** single CO_2e value for cradle-to-grave does not allow embodied capital carbon analysis. **Service life:** of 60years assumed for the specifications and component though most buildings can last longer or less.	(Anderson *et al.*, 2009) BRE Green Guide to Specification. It is publicly and freely available online by registering on the BRE website and using the specified details to log in. http://www.bre.co.uk/login.jsp **General Note:** as 86% of the greenhouse gas emission is carbon related… (cont'd below)
CapIT/ Blackbook (Capital Cost and Embodied CO_2 Guide)	**Carbon information:** the tool appears to have embodied CO_2 values not CO_2e. **Extent of information:** the tool can be used to provide the embodied capital carbon analysis. The CO_2 values of construction work activities in CapIT however exclude plant and materials transport to site. **Info required:** need to identify all related construction work items (using bill of quantities) in order to estimate embodied CO_2 values.	(Franklin and Andrews, 2010) Mott MacDonald CapIT is available for public use on a paid subscription basis. http://www.capit-online.com/ **General Note Cont'd:** CO_2e has been consequently developed for the remaining 14% composed of CH_4, N_2O and refrigerant gases for uniformity of measurement (DECC *et al.*, 2008).

CONCLUSIONS

The introduction of stringent policies and government legislation to combat climate change is making carbon an increasingly important and major metric of building environmental performance. The total carbon emissions in a building can be divided into embodied and operational carbon. Embodied carbon from cradle-to-grave are emissions generated from the formation of a building, its refurbishment and subsequent maintenance and disposal whilst operational carbon are emissions arising from the use of the building over its entire life. To address growing environmental concerns whole-life carbon counting is inevitable. There are now standardised methods and several free online tools for operational carbon measurement due to its significant contribution to whole-life carbon, and perhaps the relative ease of calculation? Similarly, embodied carbon counting is becoming relatively significant with decrease in operational carbon. Yet, there is currently no formal assessment method for embodied carbon counting and relatively not many tools available in the public domain for this purpose.

The qualitative comparison of selected open source UK tools for embodied carbon counting revealed variances in the tools. Such include different boundary definitions, general assumptions, unit of measurements, level of information required and provided, and methodological differences in calculations. Indeed, these factors will affect the applicability of the tools and the credibility of the carbon data generated. Further research will explore these aspects and also test the tools using a particular building element to identify variances in results. RICS (2012) in their draft information paper argues that a common methodology is required to determine embodied carbon of a building through its life-cycle. This and the findings of the comparative analysis of carbon counting tools suggest the need for standardisation of embodied carbon measurement and tools to regulate whole-life carbon in buildings.

DECISION-MAKING CRITERIA TO AID ENERGY-LED REFURBISHMENT OF EXISTING OFFICE BUILDINGS

Megan E. Strachan[1] and Professor Phil F.G. Banfill[2]

Urban Energy Research Group (UERG), School of the Built Environment, Heriot Watt University, Edinburgh, Scotland

ABSTRACT

Pressure is growing upon large businesses to cut their energy consumption and carbon emission levels. Many operate globally within a large and varied property portfolio; often including hard to treat properties. Property portfolio managers (PPMs) within these organisations are faced with the challenge of making informed decisions regarding the optimum energy performance improvement measures (EPIMs) for their existing properties. This study will identify and evaluate the assessment criteria (AC) that should be used when deciding the suitability of EPIMs within the refurbishment of an existing office building that is classed as hard to treat. The AC will aid the PPMs to make decisions that are informed of the true impact an EPIM will have upon an existing building across the lifecycle of that EPIM. The final stages of data collection are in progress. Four rounds of online Delphi surveys with a select group of 'energy in buildings' experts has been used to establish a defined list of twenty-two AC. The AC range from short term impact (EPIM installation) to long term impact (EPIM operation and disposal) upon the property in question. The Delphi experts are currently in the process of weighting the AC in terms of their relative importance.

Keywords: decision-making, energy, refurbishment.

INTRODUCTION

Large businesses need to respond to high level, legislative drivers for change, in the way they view their energy consumption and wider sustainability issues. Some businesses already taking the initiative to invest in low carbon technologies will view new regulations as supportive and welcome their establishment (Okereke and Russel, 2010). However, studies have found that regulatory drivers are not the salient mechanism to impel businesses to reduce operational energy levels (British Standards Institution, 2009). A prominent driver has been the identification of climate change as a strategic issue in business management and its consequential impact upon a business' competitiveness (Okereke and Russel, 2010). It can therefore be suggested

[1] mes8@hw.ac.uk
[2] p.f.g.banfill@hw.ac.uk

that many businesses do not view climate change and their resulting energy management approach as a process carried out to satisfy regulation but one that is inherent to their overall business strategy. It is in fact an economic opportunity, whether that be in the form of penalty avoidance or reduction in overhead costs. Studies have shown that the majority of professionals working within small, medium and large businesses believe that energy management strategy is very important to their business and will be increasingly so (British Standards Institution, 2009). A key element of energy management strategy is a company's property management team and how it is organised to achieve results. Many businesses now employ a dedicated energy manager who is set annual energy reduction targets, either as a contractual requirement or within a bonus incentive scheme. This pressure upon energy managers to meet targets combined with the overwhelming range of intervention options for existing buildings can make it difficult to make informed decisions when selecting the optimum energy performance improvement package. It is a complex decision making process, that can be classed as Multiple Attribute Decision Making (MADM). MADM can be characterised by alternatives, numerous attributes, attribute weights and incomparable units (Yoon and Hwang, 1995). In the context of this study, the alternatives are energy performance improvement measures (EPIM's). EPIM's have multiple attributes synonymous with assessment criteria; these are both qualitative and quantitative in nature therefore leading to incommensurable units of measurement. MADM involves evaluation of all available information and prioritisation of solutions. Prioritisation or ranking of the solutions requires some form of attribute weighting to allow scoring and comparison of alternatives. Decision-makers will have different views regarding the importance of a criterion, it is therefore necessary to use a recognised weighting methodology to determine the relative importance of each attribute/criterion. When a suitable expert participation group is applied to this methodology, a solid foundation is established to support a decision (Hamilton et al, 2007). The objective of this study is to define a set of assessment criteria against which to determine the suitability of an EPIM, and consequently aid decision making: these will subsequently be weighted. These criteria will specifically address existing office buildings, classed as hard to treat due to their traditional construction form. Traditionally constructed buildings, within the context of this study, are defined as:

1. Are likely to pre-date 1919

2. Are of mass masonry (stone or brick) wall construction

3. Originally have single glazed windows

4. Originally have no additional insulation materials built into the fabric

5. Are likely to have high air infiltration levels

Buildings of this construction type can often be found in the building portfolios of service sector and public sector organisations, providing them with a presence in many major city centres.

METHODOLOGY

A qualitative Delphi methodology was employed to achieve the objective in determining a comprehensive set of assessment criteria. Popularity of the Delphi technique dates back to the early 1960's, where it was primarily viewed as a mechanism for forecasting a future state (Gupta and Clarke, 1996). The technique has

 ISBN: 978-1-84219-840-7 .

undergone many evolutions over time, to become a method that supports comprehensive decision making, planning and problem solving. It has been used in a wide range of sectors, examples include: construction (Hon, Chan and Chan, 2011; Manoliadis, Tsolas and Nakou, 2006), healthcare (Bond and Bond, 1982; Scheffner and Rubenfield, 2000) and information technology (Schmidt et al, 2001; Doke and Swanson, 2000). However, the core principle of the Delphi remains, the obtaining of a statistically significant consensus among a group of experts in a specific field, based upon their knowledge and experience, and is implemented through a series of iterative questionnaires, combined with controlled, anonymous feedback loops (Quade, 1970).

Participants

This study required an expert group that had an insight into energy performance improvements in existing buildings. A group of thirteen experts was recruited that included:

1. Built environment professionals; involved in energy use in existing buildings.
2. Property/facilities/energy managers working within both public and private sector organisations; responsible for building portfolio energy management.
3. Experts working within official advisory and regulatory bodies; involved in energy in buildings research and guidance.

The participants were categorised into five different groups. Some of the participants could be classed within multiple groups due to their professional activities. These groups were: industry professional, industry client, guidance, heritage and non-heritage.

The number of Delphi participants recommended in the existing literature varies from ten to fifty experts (Turoff, 1970). Nor does the existing literature reach consensus on the methodology by which to select an expert Delphi group. However, it is considered that an individual who is highly skilled, with specific, specialist expertise about a subject is an appropriate Delphi expert (Oh, 1974). In addition to this, the individual must have a reasonable approach, whereby they are open to revision of their views when presented with new information (Pill, 1971). Furthermore it is suggested that a heterogeneous group provides advantages in the capture of diversified, unbiased knowledge (Hon, Chan and Chan, 2011).

Procedure

In this work, the Delphi process was facilitated by the researcher remotely, meaning that the participants could range geographically, with the majority of communication carried out electronically, via email and online survey tools. A series of questionnaires were delivered to the participants in a total of three rounds. A series of three survey rounds is recommended as a guide (Custer, Scarcella and Stewart, 1999). Time was required between each survey round to allow the facilitator to analyse and construct feedback of the experts' anonymous views. Furthermore, sufficient time was permitted to allow each participant to consider the content of each questionnaire as well as the feedback of others' views before responding. This time allowance is recognised as one of the main challenges associated with the Delphi technique (Hsu and Sandford, 2007).

The overarching question posed to the experts was, 'What criteria should built environment professionals use to assess the suitability of an energy performance improvement measure for an existing building?' This was supported by a detailed

explanation of the purpose and objective of the study, as well as contextual information relating to the specific traditional building type. The initial questionnaire was presented to the participants with a preliminary set of assessment criteria; this was derived from the researcher's fundamental knowledge and experience of the subject area. They were then provided with seven questions that allowed them to amend the preliminary criteria to align with their expertise. This was repeated twice, until the majority of participants had arrived at a consensus.

RESULTS

The preliminary set of fifteen assessment criteria was adapted and developed through the Delphi process into a set of twenty-two assessment criteria, to which all thirteen participants individually contributed. Table 1 shows the finalised set of both qualitative and quantitative criteria, presented in a format that illustrates the lifecycle of the EPIM. Concise definitions were created for each criterion, see Table 2.

DISCUSSION

Making Informed Decisions

Some Delphi participants felt it was necessary to categorise the assessment criteria to represent the lifecycle of an EPIM. This format aids the decision maker to make an informed decision, as it provides a structured, methodical approach to intervention selection (and once weighted) prioritisation. It is an approach that takes into consideration both the short and long term impacts of the intervention, upon the building in question. It encourages the decision maker to assess not only financial, but also technical, practical and social acceptability factors within the selection process. The spread of the criteria across the EPIM lifecycle is interesting in that it shows that the majority of criteria to be considered are within the operational phase of the EPIM. This may be unexpected as emphasis is often placed upon the short term impacts of an intervention. However, the subsequent weighting of these criteria will truly determine which lifecycle phase is considered to be the most important within the decision making process.

Building Occupants

The consideration of building occupants when undertaking works to a property is twofold: firstly, their comfort within the building and secondly, their understanding of how the building environment is controlled to maintain accepted comfort standards whilst simultaneously sustaining operational efficiency. The results show two criteria addressing occupancy comfort; consequently, the decision maker will consider these during the selection process. This will aid the decision maker to communicate the benefits of the works to the users. An understanding of these benefits would support and encourage participation in training of new systems post refurbishment; the third occupancy related criteria in the results.

Hard to Treat

Experts with a professional background in heritage of the built environment identified the fact that it is not only about intervention in a building's appearance, but also the building fabric. The 'loss of building fabric' was identified as a criterion in round one of the Delphi survey and then adapted to 'loss of significant, building fabric' in round two. This criterion combined with 'impact on building's appearance', and 'impact on building's internal layout/space' will aid the decision maker to realise the full impact

 ISBN: 978-1-84219-840-7 .

upon the building in question. This encourages the decision maker to consider similar criteria to those governing bodies who grant consent for intervention in properties of historical importance, therefore adding a practical element to the EPIM AC.

How the Criteria will be used

Strachan and Banfill (2012) have created an optimum approach to the energy-led refurbishment of existing, non-domestic buildings; a Decision Support Tool (DST). This DST will use the assessment criteria from this study to aid prioritisation and selection of EPIM's. The output for each EPIM will be a score. This score will allow direct comparison of each EPIM with one another. It will be an indication of how well the attributes of the EPIM meet the assessment criteria; the product of an attribute scoring matrix and assessment criteria weighting calculation. The higher the overall score, the higher the likelihood that that EPIM will be suitable for the building under consideration.

Table 1 – Finalised List of Assessment Criteria

 ISBN: 978-1-84219-840-7 .

Energy Performance Improvement Measure (EPIM) Assessment Criteria (AC)		
EPIM AC		**EPIM AC Definition**
1	Capital cost	Initial cost incurred to purchase the EPIM, including all associated transport, labour and materials.
2	Availability of grants, tax allowances and other financial incentives	The availability of financial incentives for the implementation of particular EPIM's.
3	Ease of installation of EPIM	Also known as 'buildability'. The level of difficulty associated with the installation of an EPIM, including ease of transport to and movement on site.
4	Loss of significant original building fabric	Some EPIM's installation will have a low visual impact but may result in loss of significant, original building fabric.
5	Requirement of planning and/or building control approvals	The likelihood of requiring some form of formal approval for the installation of an EPIM, including Listed Building Consent where applicable.
6	Level of disruption to building occupants during works	The level of disruption caused by the installation of an EPIM on the building occupants' working environment, and consequently their productivity.
7	Impact on building's appearance	The impact the installation of an EPIM will have upon a building's appearance, both externally and internally.
8	Impact on building's internal space/layout	The installation of some EPIM's could impact upon the gross internal floor area or the internal layout of the building.
9	Potential energy/carbon savings	A quantitative measure of the energy savings and associated carbon emission savings of installing an EPIM.
10	Financial payback	A measure of the time required to recover the initial cost invested.
11	Change to maintenance costs	A potential increase or decrease in the building user's maintenance budget due to the installation of an EPIM.
12	Ease of maintenance of EPIM	The level of difficulty associated with the maintenance of an EPIM and any associated equipment or materials. Including the availability of spare parts over the lifetime of the EPIM.
13	Reliability of EPIM's performance	The reliability of an EPIM's performance. Risk of failure in meeting predicted energy savings, as well as any other performance criteria.
14	Degradation of EPIM's performance	The potential year on year reduction in the EPIM's ability to deliver energy savings.
15	Training building occupants in the use of new system(s) post refurbishment	The level of training and regular re-training required of building occupants to ensure the EPIM is operated at its maximum efficiency.
16	Level of improvement in building occupants' comfort	The level of improvement in indoor environmental quality due to EPIM installation, consequently improving the building occupants' comfort levels and potentially, worker productivity.
17	Impact on existing building services	The impact the EPIM's installation will have upon the existing building services (BS), including building fabric improvements, as these will change the internal environment and how it interacts with the BS. Some BS-related EPIM's can have a negative impact on the existing plant and its maintenance, this must be considered.
18	Impact on building's internal air movement/ventilation	The impact of the EPIM's installation on how the existing building deals with air movement. A negative impact could lead to serious air quality and condensation issues. Also, whether changes to the building's ventilation strategy need to be considered as a result of this EPIM.
19	Impact on building's vapour permeability/'breathability	A qualitative measure of the impact an EPIM's installation has on the building fabric and how it interacts with moisture. Whether or not that EPIM is compatible with the existing construction form.
20	Disposal cost of EPIM at end of useful life	The financial cost of removing and disposing of the EPIM and any associated parts at the end of their useful life.
21	Embodied energy/carbon of EPIM	The total energy/carbon inputs required to manufacture an EPIM and its associated materials, from extraction of raw materials to reuse/recycle/disposal. This also covers the issue of EPIM availability, in terms of the energy/carbon cost of sourcing and transport.
22	Environmental impact of EPIM	The level of pollutants/environmental cost accumulated in the manufacture of an EPIM and its associated materials, from extraction of raw materials to reuse/recycle/disposal.

Table 2 – EPIM AC Definitions

DISCUSSION (Cont'd)

Weighting of Criteria

To capture the expert group's views on the relative importance of the finalised assessment criteria, they must be weighted. This is currently being undertaken by the expert group and will be reported later. Collecting expert views regarding the weighting of multiple criteria has been viewed as a preferred method over purely analytical methods (Eckenrode, 1965). However, determination of criteria weights is a complex process due to the often conflicting nature of the criteria, and an appropriate method for elicitation of the expert weightings must be carefully selected. There are many techniques available, and their attributes have been analysed and compared within existing literature (Bartlett, Heermann and Rettig, 1960; Eckenrode, 1965; Hobbs, 1980; Hajkowicz, McDonald and Smith, 2000). The paired comparison method is relatively well known within weighting methodologies and will be adopted in this next study. This is a process by which each criterion is compared with every other criterion within individual pairs, allowing the expert to indicate their rating of importance using a nine point scale. This methodology is time consuming for the experts but previous participants have concluded that it supports better understanding of the problem presented to them (Hajkowicz, McDonald and Smith, 2000). Once the expert group are satisfied with the assessment criteria and their weightings, they will then be applied to a real refurbishment project, in a follow up case study.

CONCLUSION

A set of assessment criteria, by which to determine the suitability of an EPIM for an existing, hard to treat, office building, has been defined in this study. The criteria and their presentation provide an element of standardisation to the complex multiple attribute decision making process of energy performance improvement. They consider all stages of an EPIM's lifecycle to aid an informed decision. The assessment criteria are currently being weighted in terms of their relative importance, through a pairwise comparison.

ENVIRONMENTAL AMENITY COMPARISONS IN RESIDENTIAL REAL ESTATE VALUATION

Funlola Famuyiwa[1] and Gabriel Kayode Babawale[2]

Department of Estate Management, Faculty of Environmental Sciences, University of Lagos,

ABSTRACT

Environmental valuation techniques have been used in quantifying the pecuniary influences of exogenous features of buildings. This study adopts such methods in pricing environmental amenities within the context of a housing market. The effects of both man-made and natural neighbourhood features on property prices are analyzed as derived from the status, inclinations, and implicit values of these attributes. Though the theme of this study has attracted pedagogical attention in literature, the comparison between man-made and natural environmental amenities being articulated in housing values is a nouvelle approach in identifying and explaining demand systems in relation to externalities. Using a vibrant residential property market within Lagos, Nigeria, primary data on these neighbourhood features were subjected to a regression analysis and descriptive statistics. Data used were collected with the aid of questionnaires which were administered on a systematically selected sample. Results reveal the inherent variations in the significance of physical infrastructure and natural amenities as capitalized in housing values through market process. Implications of this study identify areas of investment concentration in the face of budgetary constraints. This is expected to provide necessary guide for development sustainability in designing housing and urban settlement schemes.

Keywords: Environmental valuation, Housing market, Natural amenities, Physical infrastructure, Property value.

INTRODUCTION

Environmental amenities as a generic term refer to outdoor public goods and services that are in place to give invaluable support to man's existence and activities, whilst also providing recreational, health, psychological, and operational opportunities within it coverage area. Environmental amenities, contextually, are sub divided into man-made (physical infrastructure) amenities and natural amenities. Physical infrastructure according to Famuyiwa and Otegbulu (2012) are man-made municipal services or facilities that are designed to aid the proper functioning of productive activities in a region. These services can be provided through private or public means, and include highways, streets, roads, and bridges; water supply; waste water treatment; water

[1] ffamuyiwa@unilag.edu.ng
[2] gkbabs@yahoo.co.uk

resources; solid waste; and hazardous waste services, airports and airways; public transit; intermodal transportation as key examples More recently, the term has gone to include information technology systems such as internet services, geographic information systems, etc. On the other hand, natural (environmental) amenities are all those natural assets including green spaces that are aesthetic, ecological, and economic in nature, as well as those that have a physical or psychological effect on human health such as the provision of recreational opportunities (Gupta, Mythili and Hedge, Undated). Key examples are the presence of trees, lakes, rivers, flowers, open fields etc, within a neighbourhood.

Environmental amenities confer significant influences on the market value of properties as the components of housing go beyond just the physical structure. These goods (or services) perform important functions in aiding the activities, and health of building dwellers. For example, physical infrastructure such as pipe-borne water eases household chores. Also, the presence of natural environmental amenities (e.g. the view of a lake) within a neighbourhood impacts positively on the health and well being of inhabitants in the area. Beauchamp and Abramwoski (2012) observe that natural environmental amenities may increase the market value of a house by 5 to 25%. In the same regard, physical infrastructure also influences the market values of properties positively (See Odudu, 2003; Adebayo, 2006).

Value essentially emanates from demand, and demand arises from factors such as desirability, utility, and most especially, the ability to satisfy a need. Market Value of properties extend to encompass the components of the immediate environment, while constituting an amalgamation of structural, location, and neighbourhood attributes (Rosen, 1974). The International Valuation Standards Committee - IVSC (2012) describes market value as 'the estimated amount for which an asset should exchange on the date of appraisal between a willing buyer and a willing seller in an arm's length transaction after proper marketing wherein the parties had each acted knowledgeably, prudently and without compulsion'.

Recently, environmental issues have attracted attention in economic and real estate literature, particularly with respect to their impact on property prices. (Des Rosiers, Bolduc and Theriault, 1999). Ge and Du (2007) also observe that market value of properties is an essential aspect of property markets worldwide, and determining their value inducing factors is a significant part of the valuation process. In this process, environmental goods and services require sophisticated and 'un-traditional' techniques in arriving at their implicit values. Mishra (1998) in Holvad (2000) in Otegbulu (2010) explain that not many environmental and public goods and services have markets and therefore, prices of only a few of them could be available as comparable data. Their prices too, are only the indicators of the minimal payments at which the consumers and the producers have agreed to enter into transactions. At these prices, there may be substantial consumers/producer surpluses that go unaccounted for. The worth of environmental goods and services include these unaccounted surpluses, but their prices are not generally reflected in their worth. Hence the need to resort to Environmental Valuation Techniques such as the Hedonic Pricing Model (HPM). The HPM was birthed by Rosen (1974) and remains the most reliable tool for such purposes (Famuyiwa and Otegbulu, 2012). The model explains property values as an amalgamation of various

building characteristics viz, physical, structural and neighbourhood-related, and has remained extensively used in empirically evaluating housing characteristics. It is similarly adopted in this study to value the effects of both man-made (physical infrastructure) environmental amenities, and natural environmental amenities.

The growing awareness of the importance of nature and biodiversity especially where there is human habitation and the glaring evidence of the need for adequate and efficient physical infrastructure, for social and economic development, public health, enhanced productivity, time savings, amongst others are major considerations igniting this study. Consequently, environmental features should therefore be given adequate consideration in overall planning of the built environment. Otegbulu (2011) notes, for example, that in spite of the huge environmental and energy problem in Nigeria, designers have not seen the need for a shift from their traditional methods of designing buildings, and buildings with holistic approaches are yet to be seen.

Though previous studies have given attention to the central theme of this research, the comparative analysis of man-made and natural exogenous features of buildings has not been given adequate consideration especially in Nigeria. Consequently, this study attempts to draw a broad and concise analysis of the influences of environmental attributes (both man-made and natural) on property values. The aim is to examine value demand systems under consideration as reflected in housing prices within the study area. This is with a view for possible guidance in land use planning and smart growth development.

This paper is structured into five sections. This part has introduced the subject matter of the paper. The second section discusses key variables of this study under an apt literature. In the third part, the methods adopted in fulfilling the objectives of the study are presented. The findings and results of the research are discussed in the fourth section, followed by concluding comments and remarks in the last part of the paper.

ENVIRONMENTAL VALUATION IN REAL ESTATE – PREVIOUS STUDIES

In determining the implicit prices of value inducing variables in the housing market, several methods have been employed in previous empirical studies, with each yielding meaningful insight. Various environmental attributes (man-made and natural) have also constituted key variables in these studies. Romkaew (undated) explains that many researchers suggest that the characteristics of the local neighborhood, and environment quality are of great importance in the determination of residential property prices, but Wise et al (2010) in Beauchamp and Abramwoski (2012), remark that the difficulty lies in integrating the evaluation of multiple benefits, quantifying benefits that may not be easily monetized and bringing recognition of these values into infrastructure investment decisions by developers, communities, and agencies.

Gupta, Mythili and Hegde (undated), attempted to capture the impact of environmental, structural and location variables on housing prices prevailing in Mumbai, India. The revealed preference approach specifically concentrating on the hedonic pricing model was used to weigh the significance of key variables used in the survey with primary data using 578 households. It was found that ‘proximity to water body’ and 'garden proximity'

were the two most significant variables. Though the study highlighted the proximity to railway station as a variable in the hedonic price function, this amenity was classified as a location attribute. Moreover, there was no weighting of any other public physical infrastructure. As Kyrvobokov (2007) suggests, the comparative influence of the attributes is important and not how one or another attribute influences the value.

Jim and Chen (2007) aimed to investigate home buyers' preferences in relation to outdoor environmental attributes and also to assess actual monetary values attributed to environmental externalities using a hedonic pricing analysis. Study areas included three housing sub markets in Guanzhou, China. The variable 'green view' had the most significant positive regression (of all environmental amenities) on price in the study area. 'Buildings view' had a negative impact on housing prices in all three housing submarkets. The results of such studies in Asia may however not be extendable to a city like Lagos.

Kenyon-Henderson and Song (2008) assessed the marginal value of several types of open space in a single family residential market. In adopting appropriate research methods, the hedonic modelling was used. Variables included the property's access to different types of open spaces, propertys' structural features, public services, disamenity features, neighbourhood socio-economic characteristics, and accessibility measures. The findings were that housing prices increase with proximity to certain types of open land uses, and that the size of those nearby open spaces also impacts on home prices. More notably, the value of being adjacent to public open spaces, having more public open spaces within walking distance of the property, and being closer to the nearest open space was found greater for properties with smaller private yards.

More locally, Babawale and Johnson (2012) explored the effects of housing attributes on the price structure of duplexes in Lekki Peninsular, Lagos, Nigeria. The results suggest that the availability of 'boys quarters' and 'structural quality of property' are the highest principal determinants of prices for duplexes in the area, while the 'view of ocean/ lagoon' constituted approximately 6% of the market value of property.

In as much as it was endeavoured in this paper to concentrate the literature review on study areas with similar socio-economic characteristics, a few studies in Europe and America have proven very pivotal and indispensible in this study. Also, is the dearth of literature from local studies.

STUDY AREA AND RESEARCH METHODS

The main objective of this paper is to specify environmental attributes (physical infrastructure and natural amenities) that significantly influence the prices of houses/ residential buildings in Yaba local government area of Lagos State. Yaba Local area was carved out of the old Lagos Mainland local government which was created in 1977 as a separate Local government following the national reform of Local governments in September 1976. The area is bounded on the north by Shiro Street down to the other side of Morocco road at the roundabout to include Abule- Ijesha. It is bounded on the south by Murtala Muhammed way stretching from Jibowu to Wright street junction. On its East, it is bounded by the Lagos lagoon behind Onike, Onitiri, Makoko, Iwaya, University of Lagos communities to the lagoon, and on the west, by the descent of 3rd Mainland

Bridge to Wright Street to Murtala Muhammed way to include the Total services station at that junction. The area covers geographical coordinates 6° 29' 23" North, 3° 23' 1" East and is still one of the few existing regions in Lagos state which still draws from its colonial heritage. The area has a mix of all socio-economic classes of inhabitants, and also of mixed land uses. Yaba Local Council area wears an urban setting; some parts however mirrored rural features and these areas are simply referred to as blighted areas like Makoko and Iwaya. Nonetheless, Yaba Local Council Development area is a commercial nerve centre regardless of its political and cultural affiliations.(Wikipedia). This study however did not cover Makoko and Iwaya mentioned above, due to their slum characteristics. The decision to exclude such locations from the study area arose in order to avoid bias in the aggregate results. Characteristically, these blighted areas practically have little or no amenities; hence majority of variables employed would have no relevance if they were factored into the overall model.

Due to the apparent lack of reliable secondary data in the study area, the main research instrument used was the structured questionnaires. In selecting the sample of this study, a multi-stage approach was adopted. The first stage involved ascertaining the number of streets within the Local Government Area. The second stage involved randomly selecting four houses from each street. A total number of 45 streets were identified; consequently, 180 questionnaires were administered. 148 were retrieved, but only 106 were found useable for analysis. The homogenous tendency of houses on the same street in the study area informed the choice of this sampling approach.

The data gathered were analyzed with simple descriptive and inferential statistics. The Hedonic Pricing Model was used to bring out value inferences of various environmental characteristics used in the study. The variables were drawn from similar studies and then modified to suit the specific circumstances of the study area. As a general rule, it is better to over-specify the model (include too many variables), than to under-specify it (omit important variables) (Johnson-Gardner, 2007). Omitted Variable Bias, is introduced when key variables that should be included are not. This leads to results that over-express the importance of an included independent variable's explanatory power when regressed on the dependent variable.

A pilot study identified variables above relatively significant to property values within the study area. Further, of particular relevance is the hedonic pricing method instituted by Rosen (1974), which uses differences in property market values to identify the demand schedule for local environmental amenities, and was adopted in this study. Table 1 provides the description of the variables used for the hedonic pricing model. The table also provides the measurement of the variables used in the study.

Table 1: Definition of Regression Variables

Variables Definition	Acronym	Measurement
Net Rental Value	RTVL	Measurement in Nigerian Naira (N)
Structural Quality Of Property	STRQUAL	Good =1; Bad = 0
State Of Repair Of Property	STREPAIR	Good =1; Bad = 0
Building Age	BLDAGE	Number of years
Natural Lighting	NTLIGHT	Good =1; Poor = 0
Distance To Closest Central Business District	DISCBD	"1" if within 15 minutes driving distance, "0" if otherwise

Distance To Recreation Centres	DISRECR	"1" if within 15 minutes driving distance, "0" if otherwise
Neighbourhood Security	NEIGSEC	Good =1; Poor = 0
Neighbourhood Serenity	NEIGSER	Good =1; Poor = 0
Neighbourhood Prestige	NEIGPRE	Yes =1; No = 0
Nature Of Road Surface	NTROAD	Good = 1; Bad = 0
Government Water Supply	GWATER	Good = 1; Poor = 0
Government Waste Disposal Services	GWASTE	Available = 1; Not available = 0
Street Lightings	SRTLIGHT	Available = 1; Not available = 0
Drainage	DRAIN	Good = 1; Bad = 0
Green Environment in Neighbourhood (e.g. trees, flowers)	GRNENVR	Available = 1; Not available = 0
Private Garden Space	PGARDEN	Available = 1; Not available = 0
Wind Quality in Building (Ventilation)	WINDQUA	Good = 1; Poor= 0
Landscape Of Neighbourhood	LDSPNEIG	Good =1; Poor = 0
Navigable water Body in close proximity	NVWATER	Available = 1, Not Available = 0
View of Navigable water body	VIEWWAT	Available= 1; Not Available = 0

FINDINGS AND DISCUSSION

This section of the paper discusses the results of the research and data analysis employed for the study.

Table 2: Descriptive Statistics of Regression Variables

	MINIMUM	MAXIMUM	STD	MEAN
RTVL	60000	3600000	961095	1426100
STRQUAL	.00	1.00	.2937	.9057
STREPAIR	.00	1.00	.3773	.8302

In Table 2, the descriptive statistics of residential properties in the study area are presented. All variables asides 'Building Age' and 'Rental value' (net) were estimated using dummy measurements in coding. The upper and lower limits of the coded dummy variables were represented by "1" and "0" respectively. The average net rental value (being the independent variable) in the location is estimated at N1,426,100, with maximum value and minimum values of N3,600,000 and N60,000 respectively. The

average age of properties is estimated at 18.13 years. These two attributes were estimated with continuous variables, as mentioned above.

According to Selim (2008) in Babawale and Johnson (2012), there is little guidance from economic theory about the proper functional relationship between house price and its attributes. The estimation and selection of hedonic pricing equations has therefore been a major concern because there is not enough guidance from theory about the proper relationship between housing prices and their preferred attributes, and differences between equations and related econometric issues have been widely explored (Jim and Chen,2007; Habb and McConnell,2002). Widely used functional forms include the linear form, semi-logarithmic form, Box-Cox transformation, and reciprocal form.

The hedonic pricing regression estimates for this study are presented in Table 3. A linear model was adopted based on the preponderance of this method in similar studies.

The analysis above depicts the R and Adjusted R- square values of 0.930 and 0.865, respectively, which implies that structural, location, neighbourhood and natural environment attributes included in this model are jointly, strongly correlated with net

 ISBN: 978-1-84219-840-7 .

rental value in the location of the study. The influences represent approximately 86.5% of rental value. An R^2 value of 0.865 suggests that both the explanatory and predictive performance of the model is reasonably good. The individual relationship of each of the attributes to value is shown in the first column. Figures with negative signs imply a negative relationship with rental values in the study area. While figures with positive sign implies positive influence in rental values in the study area. From table 3, it can be seen that 'Structural quality of property' has very high and positive correlation with rental values in the study area. As expected, older buildings attract low values compared to new ones, confirming the theory that building age, and property values are negatively correlated. The study shows that every periodic increase in the age of a building will likely result in a corresponding decrease in rental values by N54,014.84. Neighbourhood attributes such as security, prestige, government waste disposal services and drainage significantly contribute to rental values in the location. Availability of good security constitutes N486,372.88 of value while 'neighbourhood prestige' constitutes up to N298,042.08 of rental value. With government providing waste disposal services, the rental value of the property rises by N731,921.49 while good drainage systems in the neighbourhood attracts high rental value to the tune of N476,864.47. Far from a-priori expectations,' nature of road surface' as an independent variable, does not constitute a positive component of rental value in the study area as can be seen in the table above.

There are six natural environment attributes that are statistically significant on rental value in the location of the study. However, only three of the attributes have positive effects. These are 'green environment in neighbourhood', neighbourhood landscape and navigable water body. Of these three, 'neighbourhood landscape' was highest with 1,475,420.31. The other two viz 'green environment' and 'navigable water body' respectively constituted N997,125.68 and N366,978.43. Environmental attributes with negative effects are 'private garden space', 'wind quality within premise's and 'view of navigable water body'. These attributes might not be expected to negatively correlate with value as recorded in this study but the incongruence might have emerged from data collection process. Same also applied to a few 'location attributes' and some' structural' and 'neighbourhood attributes'.

Although absence of serial autocorrelation among the regression attributes cannot be ruled out, the significance of F-statistic, 19.465; $p < 0.001$ implied the accuracy of the regression model in predicting rental value.
Hence, the hedonic pricing model developed from this study is stated as:

$$\begin{aligned} RTVL = {} & 668029.96 + 1941310.50STRQUAL - 1387684.32STREPAIR - 54014.84BLDAGE \\ & + 1194772.33NTLIGHT + 772926.62DISCBD + 527538.84DISRECR + 486372.88NEIGSEC - \\ & 808709.58NEIGSER + 298042.08NEIGPRE - 843059.14NTROAD - 447453.12GWATER + \\ & 731921.49GWASTE - 1345581.91SRTLIGHT + 476864.47DRAIN + 997125.68GRNENVR - \\ & 571724.74PGARDEN - 1503361.61WINDQUA + 1475420.31LDSPNEIGH + \\ & 366978.43NVWATER - 1051607.05VIEWWAT + \epsilon \end{aligned}$$

CONCLUDING REMARKS

Environmental amenity implicit costs in rental values within the context of physical infrastructure and naturals amenities for residential buildings within Yaba Local Government area in Lagos State, Nigeria were evaluated using primarily, the hedonic

regression model. Using the hedonic model, with current data, the aggregated influence of environmental attributes studied, was up to 85% of rental values. This study does not address the environmental costs and benefits of a proposed project, nor the willingness to pay for environmental amenities within the study area. The evaluation of green infrastructure vis a vis physical urban infrastructure should be a major consideration in neighbourhood and town planning schemes. According to Jim and Chen (2007), a good environment plays important roles in relieving congestion and the monotony of a built up setting and their aggregate effects contribute significantly to improving the quality of urban life, and sustainability of urban eco systems. In Lagos today, there is this continuing struggle in to adequately accommodate the influx of people from rural areas. This is mainly due to the lack of a proportionate 'rise' in land, and physical (public) infrastructure development. In settlements like this , the rapid pace of 'creating land' for new building developments has left most parts without green spaces, or natural amenities (such as trees, open fields, public gardens, etc) and the colonial fabric of the region - characterized by a well planned design, green areas, open spaces, green fields, trees, and other natural features is fast disintegrating. The evaluation of both man-made and natural environmental amenities in property prices should be given increased attention in empirical discourse. Areas of further study can be extended to consumer preference of environmental amenities as well as the willingness to pay for these amenities.

ABSTRACT

Transformative technologies such as Photovoltaic (PV) systems can substantially reduce carbon emissions of the building sector. Nevertheless, implementing PV systems requires considerable initial investments that should be recovered through uncertain savings in electricity bills. An appropriate investment valuation method is needed to conduct tradeoff analysis between uncertain electricity saving benefits and implementation costs and find the value of investment in PV systems. Currently, investments in PV systems are valued based on conventional methods, such as payback period and net present value. Nevertheless, existing methods do not address two major issues that impact the value of investments in PV systems: uncertainty and timing. In this paper, a Real Options model for the valuation of investments in PV systems for buildings is presented. It accounts for the uncertainty about respective energy saving benefits from implementation of PV systems and conducts tradeoff analysis between their energy saving benefits and implementation costs. Based on this tradeoff analysis, the proposed model identifies the optimal time to implement PV systems in buildings. This model helps commercial and residential real estate owners and investors, designers and builders, and policy makers make better decisions about the adoption of PV systems in buildings.

Keywords: building energy improvement, photovoltaic systems, proper timing, real options model.

INTRODUCTION

Buildings have a significant impact on the nation's energy use. Commercial and residential buildings use almost 40% of the primary energy (almost 40 quadrillion Btu (quads) per year) and approximately 70% of the electricity in the U.S. (DOE 2009). Transformative technologies, such as Photovoltaic (PV) systems that provide nonpolluting renewable energy are critical to meet these ambitious energy reduction

[1] baabak.ashuri@coa.gatech.edu
[2] hammedkashani@gatech.edu

goals. One of the most formidable barriers to implement PV systems in buildings is their high implementation costs. PV system implementation projects require substantial implementation costs followed by a long period of recovering the invested capital through savings in electricity bills (Supple 2010). Energy saving benefits following the implementation of PV systems should be compared against respective implementation costs, in order to determine investment values. Currently, the valuation of the investments in PV systems are made based on the conventional methods, such as payback period, return on investment (ROI) and net present value (NPV) (Muldavin 2010; Prindle and de Fontaine 2009). Existing methods do not address two major issues that impact the value of investment in renewable energy systems: uncertainty and timing.

The amount of energy saving benefits realized over time following the implementation of PV systems is subject to significant uncertainty. Existing valuation methods do not explicitly account for uncertainty about future retail prices of electricity in the characterization of energy saving benefits following the implementation of PV systems. Additionally, current valuation models are not able to determine the most appropriate time to implement of a PV system. This paper takes a different approach towards the valuation of investments in PV systems for buildings. The Real Options Theory from finance/decision science is utilized in order to overcome the above limitations of existing investment valuation methods for PV systems. The objective of this research is to create a novel investment valuation model that accounts for changes in the implementation costs of PV systems as well as the uncertainty about their respective energy saving benefits. This investment valuation model can be used to find the best time for implementing PV systems in buildings, as well as financial values of properly-timed investments in PV systems.

LITERATURE REVIEW

NPV is the standard method of current literature in the valuation of sustainable buildings (ASTM E917–05 2010; Kibert 2008; Vanek and Albright 2008). Nevertheless, despite its popularity, the NPV method has serious limitations when it comes to the financial valuation of the investments in PV systems. First, the NPV method does not explicitly account for the uncertainty about future energy saving benefits resulted from the implementation of PV systems. Second, the NPV method is inherently unable to address the investment timing (Trigeorgis 1996; Leslie and Michaels 1997). Without an appropriate investment valuation method – that addresses the uncertainty about energy saving benefits as well as the investment timing – the risk that the scarce financial resources are misappropriated is imminent. The Real Options Theory offers an alternative method for investment valuation that can overcome the limitations of the NPV analysis approach (Copeland and Antikarov 2003; Copeland and Antikarov 2003).

The term “Real Options” refers to the application of financial option pricing techniques to the assessment of non-financial or “Real” investments that are subject to considerable uncertainties and have strategic management flexibility features, such as the ability to choose investment timing. This field has gone through a significant transition from a topic of modest academic interest in 1990s to considerable, active academic and industry attention (Borison 2005). Previous research efforts have been focused on the application of real options analysis in real estate and property valuation (Ashuri 2010; Guma et al. 2009; Hutchison and Schulz 2007; de Neufville et al. 2006) and building systems design and engineering (Greden et al. 2006).

Nevertheless, the literature review indicates that real options analysis has not been applied to evaluate investments in PV systems in buildings.

INVESTMENT VALUATION MODEL FOR RENEWABLE ENERGY SYSTEMS IN BUILDINGS

The proposed investment valuation model takes into account the changes in implementation costs of PV systems, as well as the uncertainty about future energy saving benefits. It identifies the best time for implementing renewable energy systems, and establishes the financial values of properly-timed investments in PV systems. The modeling steps are:

1) The characterization of the uncertainty about energy saving benefits following the implementation of PV systems;
2) The characterization of changes in the implementation cost of PV systems over time;
3) The identification of the best time for the implementation of PV systems in buildings; and
4) The characterization of the financial risk profile of properly-timed investments in PV systems.

Characterize the Uncertainty about Energy Saving Benefits Following the Implementation of PV Systems in Buildings

Energy saving benefits are the electricity consumption costs that are avoided as a result of implementing PV systems in buildings. At any time the energy saving benefit is the product of "the amount of electricity generated by PV systems" and "the retail price of electricity." The amount of electricity generated by PV systems is specified by the system manufacturers. The retail price of electricity is multiplied by the amount of electricity generated by PV systems to determine the energy saving benefit of PV systems. Historical data show that, while retail prices of electricity rise on average over time, they are subject to short-term variations (EIA 2010). Therefore, the volatility of electricity prices makes energy saving benefits time-variant and subject to uncertainty.

A binomial lattice model for the long-term retail price of electricity

Binomial lattice models are discrete random walk models that are commonly used in economics and finance for capturing the uncertainty about a parameter that grows over time while having a random noise (Dixit and Pindyck 1994). The binomial lattice model can be used to capture the dynamic uncertainty about the retail price of electricity – denoted by R – in an approximate, discrete fashion. This modeling choice is consistent with the general body of knowledge in real options analysis (Hull 2008; Luenberger 1998).

In order to define a binomial lattice for the long-term retail price of electricity, a basic period length – denoted by Δt – is considered. For instance, Δt can be selected equal to *1* month or *1/12* year. Suppose that the initial retail price of electricity is R_0. At the beginning of the following period, the retail price of electricity is assumed to take just one of the two multiples of R_0: a multiple u (i.e., $u \times R_0$) for the upward movement of retail price of electricity and a multiple d (i.e., $d \times R_0$) for the downward movement of retail price of electricity. Both u and d are positive values while $u>1$ and $d<1$. The probabilities of upward and downward movements are $0 \le p \le 1$ and $0 \le 1-p \le 1$, respectively. This variation pattern continues for subsequent periods where the retail

price of electricity at the beginning of each period takes one of the two multiples of the electricity price during the previous period. The binomial lattice parameters *u*, *d* and *p* are determined by the following formulation (Hull 2008):

$$u = e^{\sigma\sqrt{\Delta t}}$$
$$d = e^{-\sigma\sqrt{\Delta t}} \quad (1)$$
$$p = \frac{e^{\alpha\Delta t} - d}{u - d}$$

where α is the expected annual growth rate of retail price of electricity and σ is the annual volatility of retail price of electricity. Historical electricity prices are used to estimate α and σ. A Monte Carlo simulation algorithm can be devised to generate several random paths for future electricity prices along the binomial lattice model.

Characterize Changes in the Implementation Cost of PV Systems over Time

The implementation cost of PV systems is expected to decrease over time. The decline of implementation cost may be due to several reasons including learning-by-doing, economies of scale, R&D expenditures, process/product innovation and input price declines (Hartley et. al 2010; Weiss et al. 2010; Yu et al. 2010). Experience curves can be used to characterize the cost reduction and efficiency improvement trends of PV systems over time. The changes in the implementation cost of a PV system can be modeled by a power function as follows:

$$C_t = C_0 X_t^{-\beta} \quad (2)$$

where C_t is the implementation cost at time *t*, C_0 is the initial implementation cost, X_t is the cumulative production of PV systems up to year *t*, and $2^{-\beta}$ is Progress Ratio (*PR*). Parameter β in this experience curve model can be estimated using historical data on implementation costs and cumulative productions of PV systems. An ordinary least square method is used to estimate β based on the formulation specified in Equation 2.

Identify the Best Time for the Implementation of PV Systems in Buildings

From the financial valuation perspective, a building owner, who considers investing in a PV system, can implement the system when the investment becomes profitable for the owner. In this sense, the owner holds a real option for implementing the PV system. The financial value of this real option must be determined considering the implementation time of the PV system. A risk-neutral valuation method for finding the best time for the owner to implement the PV system is devised. Risk-neutral valuation methods are developed in the mathematical finance to price options or derivatives by revising the probability measures of the underlying assets (Hull 2008). An adjustment process is needed to evaluate the investment options in PV systems using the risk-neutral valuation method. This adjustment facilitates the evaluation of investments in PV systems by allowing the use of the risk-free rate of return for discounting the stream of expected energy saving benefits. The adjustment process starts with revising the expected growth rate of electricity prices and deriving the risk-neutral expected growth rate of electricity price, which is calculated as $\alpha - \lambda\sigma$. In these adjustments, σ is the volatility of electricity prices and λ is the market price of electricity price risk. The risk premium of electricity prices λ as the underlying asset in the investment in PV systems is defined as follows: $\lambda = \frac{\rho - r_f}{\sigma}$

where ρ is the owner's expected return on investment in PV systems, r_f is the risk-free rate of return, and σ is the volatility of electricity prices. This adjusted, risk-neutral expected growth rate is used to calculate the risk-neutral probabilities of upward and downward movements in the electricity price binomial lattice model. At any node in the risk-neutral binomial lattice, the financial value of the immediate implementation of the PV system is compared against the financial value of deferring the implementation to the next period. The best time for the implementation of the PV system is when for the first time, the retail price of electricity becomes equal or greater than the respective minimum value of energy price.

Characterize the Financial Value of Properly-Timed Implementation of PV System

A probabilistic analysis method is devised that can be used to characterize the financial risk profile of the investment in the PV system considering the best implementation time as identified in the previous. The Monte Carlo simulation technique can be used to generate a large number of random sample paths for future energy prices across the risk-neutral binomial lattice model, which was created for the retail price of electricity in the previous Section. For each simulated path, it is determined whether the energy price becomes equal or greater than the minimum value of energy price and, if yes, when. This will be the best time for the implementation of the PV system. The investment in the PV system is evaluated based on this optimal implementation time. The implementation cost of the PV system occurs in the implementation time period and the stream of energy saving benefits follows the implementation. For each simulated path, the corresponding implementation cost and following energy saving benefits is determined. The difference between the sum of discounted energy saving benefits and the implementation cost is the investment value of the PV system. The risk-free rate of return is used as the discount rate in this risk-neutral valuation approach. The above valuation process for all randomly generated sample paths for electricity price is repeated and the investment value for each path is calculated. The result provides a range of possible investment values, as well as the likelihood of each investment value.

EXAMPLE

Suppose that the owner of a building located in Atlanta, Georgia, U.S.A. is considering the installation of a Crystalline Silicon Photovoltaic system. After installation, the PV system considered for this building is going to provide 7.7 KW (kilowatt) power and generate 12,000 kWh electricity per year that will be consumed in the building. An important aspect that should be considered when evaluating investments in PV systems is the decline of system performance over time due to the degradation of system components. Research (Vázquez and Rey-Stolle 2008; Dunlop and Halton 2006) has shown that the amount of energy produced by Crystalline Silicon PV systems decrease over time at an annual linear power reduction rate of .3% to 1%. For this example, it is assumed that the annual power reduction rate of this PV system is 1%. Based on the available market data acquired from industry sources (e.g., PVinsights website) the current purchase price of the entire PV system is assumed to be $4.7/W. The changes in the implementation cost of the PV system are modeled using the experience curve model. Using the industry projections, it was determined that the price of PV systems is anticipated to decrease every year due to experience curve effect (PR=0.46329). The initial price of electricity (year 2011) was

considered to be $0.10 per kilowatt-hour. The volatility of electricity prices was considered to be σ=10% per year. It was also assumed that the investor's risk-adjusted cost of capital or the discount rate ρ= 10 percent per year. Finally, the investment horizon was assumed to be 20 years. Under these circumstances, the real options analysis methodology was applied.

Figure 1 shows the probability distribution of the owner's NPV in case that he decides to implement the PV system immediately. This distribution shows the possible NPVs of investment in the PV system and the probability of their occurrences.

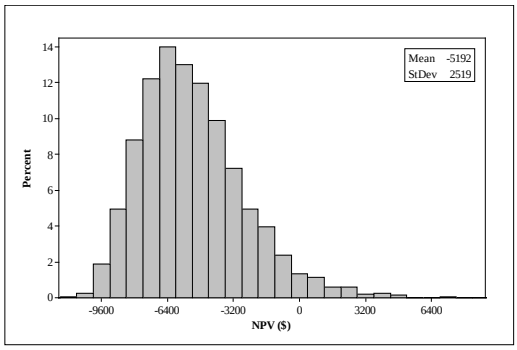

Figure 1. Probability Distribution of the Owner's NPV for Immediate PV System Implementation

Next, the proposed real options model is utilized in order to characterize the owner's risk profile in case that the PV system can be implemented at time during the investment horizon. This is followed by the identification of the minimum retail price of electricity, for which the value of implementation of the PV system exceeds the value of deferring its implementation to the following period and, therefore, triggers the implementation of the system. Thus, the best time for the implementation of the PV system is when for the first time, the retail price of electricity becomes equal or greater than the respective minimum value of energy price. Figure 2 shows these identified minimum retail prices of energy over the investment horizon.

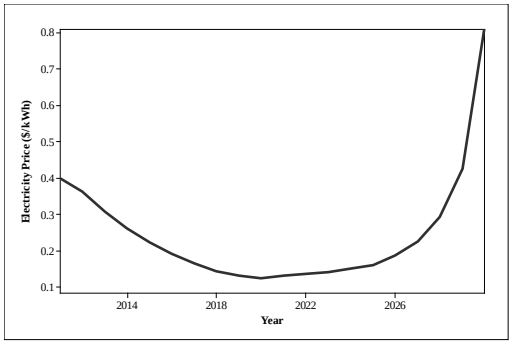

Figure 2. Minimum Retail price of Electricity that Triggers the Implementation of the PV System

Figure 3 shows the owner's financial risk profile (i.e. the CDF of the investment value) in case the implementation of PV system is properly timed. It also compares the owner's financial risk profile under this implementation option with the owner's risk profile in case the PV system is implemented immediately.

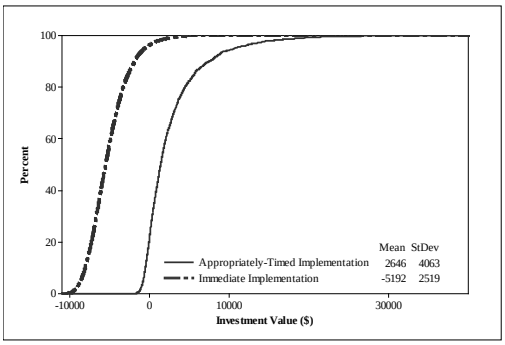

Figure 3. Owner's financial risk profile when the implementation is properly timed

CONCLUSION

The key element missing from existing valuation methods for sustainable investments in buildings is Optimal Investment Timing. The proposed real options model takes a different look at the problem of investments in PV systems for buildings. In this new perspective, a building owner with an opportunity to invest in PV systems holds an "Option" analogous to a financial call option – he has the right but not the obligation to adopt the PV system at appropriate time of his choosing. Our investment valuation model can be applied to find the optimal time for adopting PV system, as well as the financial value (if any) of delaying the implementation of PV system. Our proposed real options model is able to overcome the limitations of conventional investment valuation methods and most notably the NPV approach. It accounts for the uncertainty about respective energy saving benefits from implementation of PV systems and conducts trade-off analysis between their energy saving benefits and implementation costs. Based on this trade-off analysis, the proposed model identifies the optimal time to implement PV systems in buildings and characterizes the investor's financial risk profile under the uncertainty about energy saving benefits. Moreover, this real options model is capable of calculating the financial values of properly-timed investments in PV systems. Future research should be conducted to incorporate other sources of uncertainty, such as the uncertainty about decline in the performance of PV systems, in the valuation of investment in PV systems. This way better investment valuation models can be developed to help investors effectively implement PV systems.

PUBLIC AUTHORITIES CHALLENGE TO IMPLEMENT ENERGY RENOVATION OF CONDOMINIUM BUILDINGS IN FRANCE

Gilles Debizet[1]

[1] *UMR PACTE (CNRS, IEP, UJF, UPMF), Université de Grenoble1, IGA, 14 bis avenue Marie Reynoard, 38100 Grenoble, France*

ABSTRACT

In France in 2008, the "Grenelle de l'Environnement" Forum agreed and planned on energy renovation on private buildings to reduce greenhouse gases; the cost was estimated as hundreds of billion euros. Its implementation is actually more difficult than expected: in the absence of the obligation to renovate, public initiatives are required. Government strengthened incentive tax breaks, but they benefits mainly to the wealthiest individual home owners-occupiers. Public accompaniment of owners had always been necessary to improve residential co-owned buildings. Numerous local authorities helped them with the support of a national program first developed thirty years ago for social issues. Reducing carbon emissions recently became a new goal of the housing policies. This paper exposes a new device that French government has developed especially for energy renovation and that a few local authorities have experimented. It demonstrates that fight against climate change needs not only public grants but also local convergences with other aims and strong devices to convinced housing building co-owners.

Keywords: boundary object, housing improvement, mitigation, OPATB, thermal refurbishment.

INTRODUCTION

The residential and tertiary buildings represent 43% of final energy consumption and 23% of greenhouse gazes (GHG) emissions in France. Although this sector emits less as transport, it appears to be the best way to reduce French GHG emissions and, so, to mitigate climate change. Since 1975, the construction sector has adapted to successive reinforcements of energy regulation. Thank to a high thermal insulation, new buildings consume nearly ten times less energy than the average of existing buildings. This makes plausible a factor 4 (a 75% decreased in GHG) by 2050 if a substantial part of the current buildings stock will be renovated.

Housing represents the majority of the built surfaces. Private owners own 4/5th of all housings. The disjunction (Berdoulay & Soubeyran 2002) between the scale of the problem (global warming) and the decision scale (each housing) cannot be greater. The possible solidarity towards the planet from the owners will not be sufficient to reach the factor 4 in France; energy renovation requires governmental actions.

[1] Gilles.debizet@ujf-grenoble.fr

The French government strengthened incentive market measures in 2005: the tax break is the main one. In 2008, the State spent therefore 2.8 billion € for 1.6 million households who spent themselves 8.2 billion € of work. This tax break benefited almost entirely (95%) to occupiers owners (57% of housing belong to occupiers owners and 25% to renter owners). Among the French households, the fifth wealthiest benefited six time more of tax breaks than the fifth poorest. Owners of single-family dwelling are overrepresented (56% of French housings, 81% of tax break beneficiaries) (Clerc & Mauroux, 2010).

The limits of tax break for housing improvement are known for several decades. During 70s, the Housing Ministry had implemented a grant device in partnership with local authorities: this device targeted non-occupiers owners and modest occupiers owners. It has often been essential for condominium improvement for a main reason: work decision requires a large majority of co-owners. Unlike tax breaks, partnership devices involve local governments during several years. At least, three levels of "government" are involved: national, local and, of course, condominium.

How these different scales of government integrate the issue of climate change mitigation? How mitigation policies should be implemented for the condominium buildings?

We assume that the content of mitigation policies is determined by involved organizations: not by one of them but by their interactions. Therefore, we consider partnership projects and multi-scale devices as boundary objects (Star & Griesemer 1989, Aibar & Bijker 1997, Trompette & Vinck 2009, Debizet & Symes 2009).

This paper focuses on the experimental partnership device developed by the state and applied by several local authorities in order to mitigation: OPATB device. The first part considers the OPATB device as a boundary object involving different ministries with their specific organization: knowledge, procedures and aims. The second part shows the high degree of investment of local governments and the interactions with territorial issues: it also illustrates the necessity to implement mitigation on a local scale.

OPATB AS A NATIONAL DEVICE FOR MITIGATION, COMBINING SOCIAL AND ECONOMIC ISSUES

Housing and Economic Ministries have overseen national policies relative to housing improvement. Climate change leaded the Ministry of Environment to promote building energy renovation. In absence of obligation to renovate, they developed together the OPATB device.

An obligation to renovate legally or politically difficult to set up

Since its inception in 1975, building regulation has established minimum energy efficiency; it applies only to new buildings, i.e. those submitted to an authorization procedure. Concerning existing buildings, an energy performance assessment must be associated since 2009 with the sale (or rent) of housing; however, it only informs the buyer (or tenant). In addition, minimum performances of products are imposed on professionals: i.e. when they replace windows.

In 2007, the mitigation of climate change was one of the main issues of the French presidential race. Incumbent President Sarkozy avoided specific commitments, but vowed a broad consultation on the environment and climate change. During the "Grenelle Environnement" of the Forum, all participants agreed to mandatory energy renovation of buildings. However, a few months later,

 ISBN: 978-1-84219-840-7 .

the "operational building committee" was reluctantly argue about the solvency of owners and the difficulty in defining the verifiable obligations. Laws that apply the "Grenelle Environnement" does not actually impose a general obligation. In the absence of requirement to undertake energy renovation, incentive provisions have been promoted for several years and shall be developed for may years.

Preexisting economic incentives for owners

With 1.5 million jobs, the construction sector is one of the country's first economic sectors. As such, tax cuts for individual investors and zero-interest loans have sustained construction. Progressively, French government strengthened these incentives in case of energy efficiency work.

Tax cut and loan subsidies have always been insufficient to stimulate the landlords and modest homeowners. The former do not benefit directly of energy savings. The latter have little capacity to finance work. These two categories can receive grants from the national agency for housing improvement (Anah). Created by the State in 1971, Anah *"encourages and facilitates the execution of improvement work and housing adaptation."*

In 2008, Anah distributed two thirds of the 526 million euro of grants within local scheduled operations of housing improvement (OPAH: Opérations programmées d'Amélioration de l'Habitat). Specifically, local authorities increase the fund and define the perimeter, the goals and some grants level in consultation with Anah. Finally, the owners receive more grants than Anah usually gives outside of an OPAH perimeter (Anah 2009).

The first scheduled operations were signed with local governments in 1977, as part of urban renewal of neglected and unhealthy historic districts (Gravejat 1991). Gradually, Anah has expanded the device to economic and social aims. During 90s, energy savings appeared progressively as a lever of housing improvement.

Before partnership convention, pre-operational studies clarify the scope, work types and calibrate both subsidy levels and partners financial budget. The subsidy rate should be high enough to trigger reinvestment from private actors and low enough to respect the budget of each partner. The result is uncertain because owners (or condominium corporation) actually choose the work and, therefore, decide whether or not to use the subsidies.

OPATB national device genesis

Ministry of Housing (supervisory authority of Anah) and the Ministry of Environment (supervisory of Ademe) introduced OPATB device in February 2002 as a call for local authority projects. *"The OPATB are intended to act locally on residential and commercial buildings to reduce their energy consumption and CO2 emissions"* (Ademe & al. 2002) The OPATB device actually fitted into the mold of Scheduled Operations of Housing Improvement (OPAH) that have proven efficient since their creation in 1977 by Anah. However, the principles of call for project and the criteria to select communities correspond to Ademe procedures.

Agency for the Environment and Energy Management (Ademe) implements environmental policies carried by Ministry of environment. It also offers its expertise to local authorities. Ademe calibrates its devices to bring out innovative experiments and facilitate its diffusion. Then, national or local governments often contribute, by grants or tax cuts, to the diffusion of a sustainable innovation initially funded by Ademe.

Ademe considers OPATB (operations rather than the device itself) as innovative experiments: "*The multiplicity of targets must create genuine competition among professionals and increase synergies [...] between building partners".*

Ministries validated the OPATB device. They ensured compliance guidance to key moments and the communication fallout. Then, Anah and Ademe have implemented the device in partnership with local governments:

- Anah fulfills its mission: aid landlords and modest tenants. It masters the operational methods: targeting buildings, defining scope and ways of grants...
- Ademe funded energy studies, technical animation, final evaluation and some high performance work. It manages also the experiences exchange network.

Ademe and Anah envisaged twenty-six local OPATB: "The *future multiplication of OPATB depends on the success of these first OPATB.*" Only 16 OPATB were underway in 2007. However, a growing number of OPAH incorporates "energy" as one of their goals: 273 of 715 ongoing OPAH in 2009.

***

During the OPATB device gestation period (2000-2002), Ministry of Housing (Besson 2000) appropriated the goal of climate change mitigation (targeting global solidarity) in addition to initial goal of saving energy (targeting the purse of owners and occupiers). OPATB device hybridizes OPAH (Anah) and innovation funding (Ademe), it finally encourages Anah to develop energy goal in the OPAHs. Ministry of Environment and Ademe increased their legitimacy and their visibility on the housing sector. OPATB device appears as a transient boundary object between the sectorial Ministries and between their agencies.

Let us observe how the OPATB device implements the mitigation on a local scale.

GRENOBLE AND ECHIROLLES OPATB

Six of the thirteen OPATB operations implemented in 2006 were located in the Rhône-Alpes, one of the most dynamic regions in terms of sustainable building (Roudil & al. 2008). We choose the cases of Grenoble and Echirolles because these OPATB mainly concern condominiums. Anah and Ademe selected Grenoble in 2002 and Echirolles in 2004.

After describing the OPATB process, we explain how local authorities approach OPATB. Then, we summarize the results of Grenoble OPATB .

A lengthy and complex implementation: i.e. Grenoble OPATB

Three years were required to define the Grenoble OPATB (two years for Echirolles). The implementation convention, signed by Ademe, Anah, the city of Grenoble, the State and Grenoble Alpes Métropole (the metropolitan authority) in October 2005, described the quantitative targets, the financial commitments, the subsidy rules and the terms of animation, monitoring, evaluation and control.

Once signed the partnership convention, the operational stage began with a long and tedious work of information to storekeepers, condominium boards and managers in order to encourage them to initiate an energy audit. After its energy audit, the

 ISBN: 978-1-84219-840-7 .

condominium board was accompanied for one or two years until a majority of co-owners votes (or does not vote) for thermal work during the annual condominium meeting.

When many boards of condominium planned to propose energy renovation at their annual meeting, the city left proactive communication. It avoided to involve new condominiums and, therefore, to exceed the OPATB budget.

The figure below illustrates the process. The city ("Ville de Grenoble") steered the OPATB process and the condominium board ("copropriété") steered the building renovation project. During work, city subsidized 20% of work cost to the condominium. The housing owners received subsidies based on their individual situation.

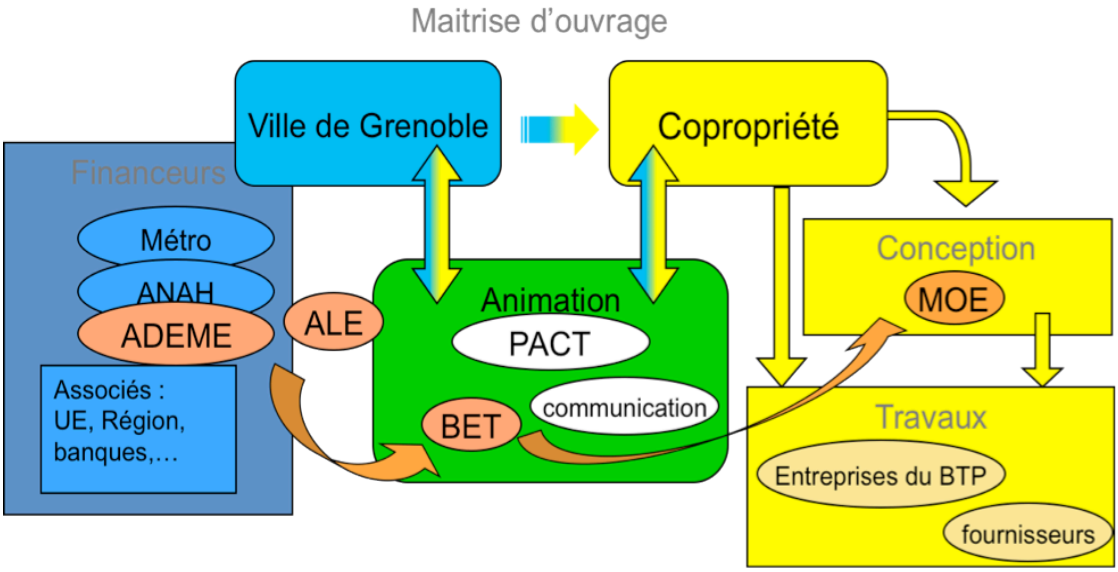

Figure 1 OPATB Grands Boulevards process. (Source: Debizet based on figure of Carré, PACT de l'Isère 2009)

Funded by the signatories of the OPATB agreement (blue or dark gray), the animation device (middle) aimed condominiums (green or light gray) to drive the energy renovation project: each condominium recruited a contractor. Each category had a technical expertise (orange or gray): this facilitated the knowledge transfer to architects ("conception") and contractors ("travaux") and the control of thermal performances by Ademe.

OPATB animation combined the contribution of technical, organizational, financial and communication experts. A non-profit association (PACT), specialized in assisting housing improvement, coordinated the animation team.

City of Grenoble: an urban project became an illustration of the energy-climate local policy

At the stage of pre-operational studies, perimeter covered a band of four hundreds meters around the new tramway lane through the city. Three kinds of building were targeted: tertiary public buildings, small shops and condominium housing. The scope of these last two had been restricted. The 'Small shops' only concerns facades along the new tram lane (orange line below). The perimeter "Habitat" (green line below) applies to all blocs along the tram lane (green line below).

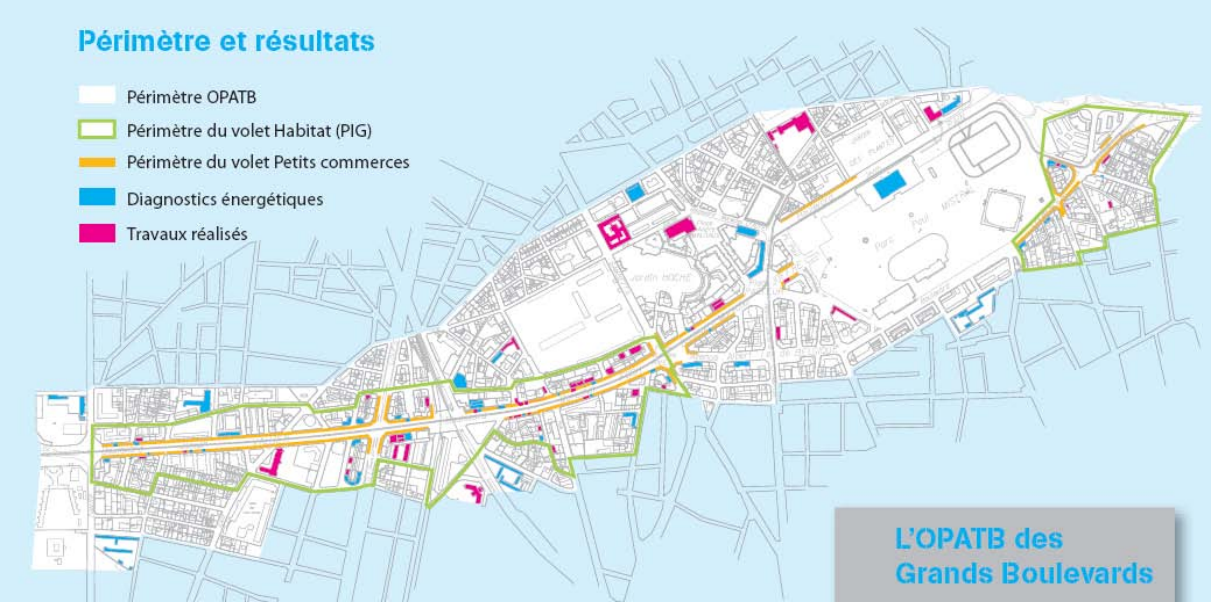

Figure 2 Perimeter and and results of Grands Boulevards OPATB (Source City of Grenoble : OPATB assessment)

Realized where fortifications protected Grenoble city center until 1938 (Parent 1982), the Grands boulevards are currently lined by tall buildings built between 1945 and 1967. Their energy performance was poor.

Several major urban projects concerned this area: highway bridge demolition, new tram lane, traffic calming measures, building facelifts and also building a green district nearby (De Bonne). The city council expected to reduce urban break between the wealthy historic center and the suburbs built during the post-war boom.

"*The intervention on the Grands Boulevards is part of a global project of territory conquest and transformation.*" explained the mayor in the 2006 brochure of the OPATB addressed to the inhabitants. It also supported the tram lane success, which some storekeepers opposed. The brochure advertised three aims: revitalizing the shops, improving buildings thermal performance, and enhancing architecture. OPATB's slogan "new air on the Grands Boulevards" exalted the aesthetic as much as climate.

Three years later, in 2009, the tramway lane was so popular with inhabitants and most of the storekeepers, that the ideal of urban continuity became useless. Now, apart from technical communication to owners, the city exposes OPATB as a flagship project of its "Grenoble Factor 4" program. "Grenoble Factor 4" is de facto the Municipal Climate Action Plan and a new ideal for the city's future (Henry 2008). The renewal of the City Council in 2008 confirmed this trend by moving the OPATB political leadership: the deputy mayor in charge of Sustainable Development replaced the deputy mayor in charge of Urban Development.

City of Echirolles: OPATB as an action of the sustainable development program complementary to major urban projects

Second town of the Grenoble urban area, Echirolles has been urbanized since 30s. In the 60s, social housing and condominiums buildings had started to grow alongside the working-class individual house area around main industrial sites. For the last twenty years, the city has built a true urban center around a tramway lane, which is the communal territory epicenter. Ten years ago, the city council launched an Agenda 21. It has mobilized residents and city staff around shared objectives by focusing on social

and environmental synergies. It took care to cover all areas of the city and, both, the diversity of sectorial thematic and the different categories of people. Since then, it has led to systematic follow-up actions with the residents.

Figure 3 Perimeter and posters of West Echirolles OPATB. (Source: City of Echirolles)

The OPATB "Echirolles West" conveniently filled the hollows of Agenda 21 and of a vigorous urban policy. First, the western districts did not benefit from the public facilities of the Echirolles city center. Second, the various actions on buildings conducted by the city did not relate to existing private buildings. The western districts focused on the higher proportion of private housing (mainly condo) and weaker political relays of the city leftist majority. Compared to Grenoble, OPATB communication emphasized household interest and, implicitly, global solidarity but it ignored the urban dimensions.

Grenoble Alpes Métropole, the metropolitan authority: embrace a new skill

Partner of Grenoble and Echirolles OPATB, the metropolitan authority (commonly called "The Metro") abounded them on its own budget. This institution is in charge of metropolitan transport, economic development, social housing and some environmental issues (atmospheric pollution, road noises, waste...) but not urban planning. The Metro created in 1999 the Local Energy Agency, which provides expertise and advice to local partners, businesses and residents. The Metro was one of the first French Métropole to develop a Local Climate Action Plan (presented in May 2005). It introduced early the climate change mitigation goal in its housing and transport policies, and mobilized the cities of the area to develop climate policies (Debizet 2009). It steers the "Mur Mur" device that succeed to OPATB from 2010.

Restricted to an animation and incitement in urban planning role, the Metro will initiate and facilitate innovation in the building industry that remains one of the main economic sectors and provides the majority of the metropolitan taxes.

Minor contributors to both OPATB operations

The **Rhône-Alpes Region** funded energy audits and some solar water heaters or photovoltaic panels. In addition to GHG reducing, the action of the Region has been

part of an economic development of solar and green building sectors (Roudil et al. 2008). Non-signatory to the OPATB, the Region did not participate in their targeting.

Under the European Concerto program, **European Community** funded a tenth of the OPATB animation. This funding was acquired several months before signing the partnership convention; City of Grenoble might make choices more vigorous.

Results of Grenoble OPATB

When Grenoble OPATB period (2007-2010) ended, a quarter of eligible condominiums (22 condos grouping 637 apartments) had decided to realize thermal improvement work. Unlike previous OPATB partnership convention, their work consisted almost entirely in adding external insulation. OPATB granted 1.6 million € of the 5.5 million € work and spent 0.6 million for animation and expertise (Debizet 2010).

Grants represented 30% of work cost for an average owner. However, this rate depended on owner status and income. It varied from 35 to 80% for non-occupiers owners (landlords) and from 20 to 80% for occupiers owners. These rates did not only result of social issues. They were required to find a majority in favor of energy work during the annual condominium meeting:

- Because national law restricts the rent increase, landlords do not benefit of energy renovation when they keep the housing. Therefore, they need grants to maintain profitability of investment. Among them, the less wealthy and the older have to be helped because they cannot get a bank loan.

- The poorer and the older occupiers owners have also to be more helped. First, they cannot benefit of tax breaks and bank loan. Second, the profitability of their energy renovation investment is lower than that of the wealthiest occupiers owners because their initial energy bill is low (they already try to save energy).

Owners can also benefit from national tax breaks on the balance after OPATB grants. Failing of specific statistics, we assess that tax breaks represent roughly 10% of the global work cost. According professionals involved in the OPATB, tax breaks are not decisive for modest owners.

The Grenoble OPATB helped reduce annual carbon emission of 575 tons. Therefore, energy renovation cost 10,000 euros to reduce annually one ton of carbon: OPATB partners (including state) funded directly 4,000 euros and state funded 1,000 euros through tax breaks.

***

Local authorities consider OPATB as an opportunity for a wider project (or policy): sustainability program (Echirolles), urban project or climate plan (Grenoble). The specific priorities of local governments influence perimeter and targeted population. Anyway, the initial convention and the partnership steering committee ensure that the implementation respects the aims of mitigation and energy saving. We missed place to describe the cognitive and organizational aspects. The concept of boundary object could also be useful to describe the interactions of local governments and national agencies especially in order to analyze the outstanding issues of energy renovation policies.

CONCLUSION

The energy renovation appears a consensual mean to reduce GHG emission. However, it requires a high level of investment. The wealthier occupiers owners of individual

dwelling can expect a financial gain thank to energy saving; they benefit easily from tax breaks and are able to quickly decide insulation work. The collective housing owners do not have the same abilities. A local accompaniment is necessary; it combines variable grants and a socio-technical mediation.

Unlike one ministry, local authorities consider the scheduled operations of energy improvement as a transversal element to their different policies. They will have to face the antagonism between mitigation and social goals (Debizet 2011). Maximizing GHG emission reduction of a given budget leads to orientate public funds toward the wealthier condominiums.

On another scale, French government should adjust the rate of tax break according household income and dwelling type. It should also increase the part of scheduled operations within its overall budget available for energy renovation. Anyway, it cannot avoid the debate between mitigation goal and social priorities. Further analyzes of the local implementations of mitigation could feed this debate.

PUBLIC ENGAGEMENT AND PARTICIPATION IN SUSTAINABLE TRANSPORT ISSUES

Professor Richard Laing[1], Dr Elizabeth Tait[2] and Professor David Gray[3]

ABSTRACT

Currently, emissions from transport represent a quarter of Scotland's total. While the Scottish Government has identified a number of transport policies, which would contribute to Scotland's ability to meet its targets, action to significantly reduce greenhouse gas emissions from transport has been limited, poorly integrated with other areas of policy, and focused on narrow programmes. Drawing on best practice from cities across the North Sea Region, this paper considers how public engagement can be utilised within the development of holistic low carbon urban development. Consideration of regions where strategies have been successful reveals a context where transport is considered as part of wider urban design and urban development, thus ensuring that the potential benefits are directly related to concerns of planning, housing and behavioural change. The paper includes information and conclusions from a case study in Aberdeen, Scotland.

Keywords: participation, climate, regional, transport, urban.

INTRODUCTION

In the coming years, urban areas across Europe will increasingly be required to respond to the challenges of climate change. To date, this has been reflected in numerous European directives and initiatives, including those within the Strategic energy technology plan (SET), the smart cities initiative and CIVITAS. Within these initiatives has been a recognition that decisions made in the planning and management of our cities will have direct and often complex implications for the environment. A central part of the underlying philosophy is an understanding that such complexity extends across the built environment, infrastructure, transport provision and human behaviour. The research reported in this paper considered how the development of sustainable urban transport strategy can benefit from the direct implementation of strategies to engage end users. Particular challenges relate to the balance between spatial planning, consumption and behaviour, and the development of new and extended urban centres. Indeed, it is clear that behavioural change will be central to

[1] r.laing@rgu.ac.uk
[2] elizabeth.tait@abdn.ac.uk
[3] david.gray@rgu.ac.uk

meeting climate change targets, thus suggesting that participation of users at the design stage carries potential to greatly improve end results and modal shift.

In response to concerns about climate change, air quality and sustainable development in general, local governments around the world are facing challenges to develop and implement carbon reduction initiatives. The challenges they face are daunting for many reasons that are well documented in the literature. Barriers to policy implementation include: limited resources for developing new infrastructure and services, institutional and policy barriers, social and cultural barriers, legal barriers, unintended consequences and side effects (Banister 2005). There are, however, examples of best practice where cities have developed effective carbon reduction initiatives and numerous projects have been developed to try to transfer knowledge and best practice between local governments.

This paper draws on experiences from CARE North, an Interreg-funded initiative (IVB North Sea Region Programme) aiming to develop *'a comprehensive, strategic and practical approach to urban and regional transport accessibility in the North Sea Region'*. CARE North extends across 9 partners and 4 countries, and includes input from ICLEI, an association of local governments committed to sustainable development. The project was initiated in response to concerns about climate change and recognition of the need to reduce transport-related CO_2 emissions which continue to rise (despite per-vehicle emissions falling) and pose a significant threat to health. The northern European region is interesting in that, whilst there are partially shared climatic and cultural contexts (particularly in the Nordic and Celtic countries), the rate at which sustainable transport has been adopted across cities and regions varies greatly. For example, Bremen, Germany (see Figure 1) has implemented an extensive network of bicycle share hubs, which help to normalise the use of low carbon transport across the city. Coupled with an extensive tram network, use of the city centre for many is aided and defined by the ease with which pedestrians and cyclists are able to share the space with motor vehicles. An early pioneering city with regards to a shift towards walking and cycling was Copenhagen, Denmark, which today is arguably defined by its fully integrated walking, cycling and rail networks, including an expanding underground system (Figure 2). The success of such schemes lies in the demonstrable shift in modal share between walking/cycling, use of public transport and car use. Of great importance, also, is the manner in which the schemes have been designed to integrate with daily lives, rather than to demand radical shifts in lifestyle. Therefore, in addition to institutional and political challenges, there are challenges of public engagement that must be taken into account. Transport policies can be very controversial, especially if they attempt to change travel behaviour by restricting access or increasing cost. It is therefore considered essential that members of the public are engaged in the process of the development of such initiatives. ‘Overcoming barriers to effective implementation requires interactive and participatory processes, so that intentions and outcomes of policy interventions to achieve sustainable transport coincide.’ (Banister 2005)

However, as reported in the literature, there are great challenges of transferring carbon reduction initiatives between cities. Initiatives that are successful in one area will not necessarily be successful when transferred to other cities for many reasons. (Marsden et al. 2010) recommend that local governments need to develop a culture of learning from others which takes into account all aspects of the implementation of the initiatives but that that learning should 'be approached with scepticism about the full scale and transferability of benefits'.

CONTEXTUAL REVIEW

Public engagement and participation

A dimension related to the successful adoption of carbon reduction initiatives in local authorities is public participation and engagement. Local authorities have a statutory duty to consult citizens and public engagement through Community Planning Partnerships forms a core part of the Single Outcome Agreements between the Scottish Government and Local Authorities. Participatory initiatives are believed to help overcome public disengagement with politics (Dalton 2004). Public participation is believed to: increase the accountability and transparency of government institutions, broaden the base of political participation and create more active and engaged citizens (Smith 2009). Participative policies are also believed to play a role in educating the public and increasing civic awareness (Darier & Mehta 1998).

As well as having a positive impact on the legitimacy of policies and decision-making it is also argued that public participation initiatives such as 'planning for real' may have a positive impact on the policies themselves making them more suitable to the needs of the people than policies devised at the local authority level (Smith 2005). The role of participation is seen as being more than just creating effective policies, however. There is also a broader issue of engagement that is being sought to overcome the problem of the democratic deficit and apathy towards politics within the general public that is perceived to be occurring at the local level in order to make the institutions of government more responsive and legitimate (Chandler, 2000).

As demonstrated earlier in the paper, however, the aims of public participation go beyond policy development and also have educational and broader goals of engagement which cannot be measured in policy outcomes. In order to effect behavioural change it is argued that people must understand the impact that their choice in transport is having. (Bickerstaff & Walker, 2001) investigated the way that the public perceive air quality issues and found that people tend to have a highly localised view of air quality which draws on physical and spatial criteria as well as cultural and economic factors.

Policy context

One of the big challenges for trying to analyse how transferrable a carbon reduction initiative will be from one local government to another is the policy context. There are multiple layers of interconnected government in the UK which all have a bearing on transport policy and are themselves influenced by European and International level treaties and laws. An excellent analysis of Multi-Level Governance for carbon reduction policies in the UK was conducted by Marsden & Rye, (2010) who identified the limited sphere of influence that local authorities have:

"The main policies for local carbon reduction which authorities have control over are parking allocations for new development, smarter choices and improvements to walking, cycling and public transport (bus) infrastructure." (Marsden & Rye 2010)

Financial restrictions place further limitations on local authorities' work which has an impact on their ability to implement carbon reduction policies, especially if these involve investment in infrastructure etc. There are strict rules on local authority spending and limitations are put on the raising of council tax. The Scottish Government, for example, has frozen council tax for the duration of the 2011-2016 parliamentary period in keeping with the SNP manifesto pledge (Bell 2011).

 ISBN: 978-1-84219-840-7 .

Urban context

Everyone makes daily decisions about where to go, how to get there, and what to do when they arrive. The perceptions of quality and safety of the spaces involved will influence many of these decisions and activities (e.g. the safety and attractiveness of routes travelled to and from work or school etc.). Therefore, the quality of public space and urban streets is important. Oxford Brookes (ODPM 2002) note that typical concerns relating to public spaces may include unsafe streets and public spaces that foster anti-social behaviour, crime and the fear of crime; dirty streets and public spaces; and, unattractive and inaccessible parks, play areas and open spaces with poor provision for children and young people, older people and disabled people. Rather, the buildings are important specifically because of the manner in which, even at a small domestic scale, they serve to provide evidence of the history of the societies and cultures from which they emerged. Therefore, it can also be argued that the value of our cities extends well beyond concepts of financial value (e.g. in a cultural context, Shipley 2000), and that choices made regarding the relative positioning of the pedestrian within cities will greatly define the public realm (e.g. Gehl 1987, Gehl and Gemzøe 2006).

CASE STUDY: ABERDEEN

Aberdeen is the third largest city in Scotland with a population of approximately 216000 people. The economy of the city has been boosted considerably by the North Sea oil and gas industry which has to a large extent insulated Aberdeen from the global economic recession and has contributed to Aberdeen having a very low unemployment rate and a higher than average wage rate for Scotland (Aberdeen City Council 2012). Car use in Aberdeen City is high with 42% of residents reporting that they use a car every day compared with the Scottish average of 33%.

The key policy document for understanding Aberdeen City Council's transport document is the Local Transport Strategy which sets out the vision for ACC's strategic plan for the city's transport infrastructure and services until 2012. The plan recognises that there are significant problems with congestion and air quality in Aberdeen (Aberdeen City Council 2008) but indicates a high level vision to develop a sustainable and accessible transport system, which a vibrant economy and minimises the impact on the environment. The strategy makes specific mention of carbon reduction initiatives including: reducing the need for council staff to travel, encouraging lift sharing, developing car clubs and encouraging the introduction of low emissions vehicles. The strategy is closely linked to the Air Quality Action Plan which aims to reduce the problem of poor air quality in Aberdeen City Centre (Aberdeen City Council 2011).

SURVEY AND RESULTS

In order to study public responses to a range of local proposed initiatives, an online survey was run to gauge levels of support and reaction. The total response rate to the CARE-North questionnaire was 627 which could be considered a good response rate to a public engagement questionnaire.

It was found that the vast majority of respondents regularly travelled in to the city centre with 73.7% indicating that they worked in the City Centre, 32% indicating that they live in the city centre and 77.3% indicating that they travel in to the city centre for shopping and or leisure reasons. Only 3.8% of respondents indicated that they never travel in to the city centre.

 ISBN: 978-1-84219-840-7 .

Mode of transport used by respondents

In keeping with the high levels of car ownership within Aberdeen itself it was found that 86.1% of respondents reported having one or more cars in their household. It was found that travel by car was the most frequently reported mode of transport used by respondents for journeys in to the city centre across a range of activities including: travel to work/school/university, leisure activities during the day, leisure activities in the evening and shopping. The second most frequently reported mode of transport was walking followed by the bus. These results were also reflected when respondents were asked to rate the relative ease of travelling in to Aberdeen City Centre. Respondents were asked whether they considered that Aberdeen City Council had a good active travel network including walking and cycling (promotion of active travel is one of the ambitions of the local transport strategy). The majority of respondents (52.5%) disagreed or strongly disagreed with this statement with only 2% strongly agreeing with this statement.

Respondents were asked to rate a range of factors to determine their relative importance in terms of influencing their decision to use public transport. The factors that were most likely to influence respondents' choice to use public transport were:

- Reliability of the service
- Frequency of the service
- Cost

Respondents were then asked to rank a series of factors in terms of how they dictated their choice of transport. In keeping with previous responses it was found that convenience was the main factor that influenced choice of transport, followed by reliability, time taken and cost. Environmental concerns were rated as the lowest concern amongst respondents.

To determine whether the local transport strategy matched with public beliefs about priorities for transport, respondents were asked to rate the importance of the priorities. It was found that all five priorities were rated as important or very important by a majority of respondents with 'Safe and Secure Transport' ranked highest followed by 'Minimise the environmental impact of transport'

Awareness of air quality issues

Respondents were provided with information about the air quality issues in certain areas of Aberdeen and were asked whether they were aware of these issues. 36.7% of respondents indicated that they were aware of air quality issues with a further 27% indicating that they were partly or possible aware. 36.2% of respondents indicated that they were not aware.

Respondents were then asked about how concerned they were with regards to their health or the health of their family about the level of pollutants. In total 48.1% of respondents indicated that they were concerned or very concerned about these issues.

Respondents were then asked about the extent to which they considered different issues were contributing to air problems. The factor that was considered to be of greatest concern was pricing of public transport, followed by congestion. Connectivity of different modes of transport was also considered to be a significant factor as was the routes that public transport take.

Initiatives

It was found that 64.7% of respondents indicated that they supported the idea of a low emissions zone in Aberdeen City Centre. Of those who supported the LEZ, 93.9% indicated that Lorries should be restricted/discouraged, 59.4% indicated that cars should be restricted, 20.3% indicated that taxis should be restricted and 19.3% indicated that buses should be restricted.

Respondents were asked whether they believed that the introduction of car clubs would reduce the number of cars in Aberdeen City Centre. Approximately 35% of respondents indicated that they believed they would, 32% indicated that they would not and 33.3% indicated that they did not know. 19.4% of respondents indicated that they would consider joining a car club.

Results from the survey are interesting at a local level, as they demonstrate a genuine interest in the impact of transport and choices on the environment, with broad public support for a range of initiatives. The earlier part of the paper, though, indicates that cities where initiatives have been implemented on a wide scale, that this has been integrated in a holistic approach to city development. Local policies to address issues of transport in the city and region are in place, and can arguably draw on such indicative public support to move from planning to implementation.

DISCUSSION AND CONCLUSIONS

This paper has described contextual and applied research undertaken across the North Sea Region, with particular regard to the integration of public engagement and wider concerns over sustainable urban transport. The importance of understanding the relationships between urban development, and issues of transport, user choice and human contact has been studied previously (for example, van den Berg 2011, Marchal and Nagal 2005). Similarly, the subject of spatial development (e.g. development of new towns) and how this can integrate with and support sustainable choice with regards to transport (Dijst et al. 2002) will become increasingly important to strategies within Scotland in the coming years, as pressures increase on urban density. It will be important for cities such as Aberdeen to recognise that new housing must be integrated with viable sustainable transportation, as is the case in CARE North partner city Gothenburg, for example. The research ultimately calls for an holistic approach to urban development, which recognises the integrated importance of robust policy, user participation within design and strategic development and a recognition of the importance of behavioural change, in addition to the provision of new infrastructure.

ACKNOWLEDGEMENTS

The research in this paper was part-funded through CARE North, a project supported by the Interreg IVB North Sea Region Programme (www.care-north.eu).

ABSTRACT

Research presented in the paper updates the analysis from a previous paper, which was presented at COBRA 2010, in Paris. The situation with women and work in Apartheid South Africa was very discriminatory. Post-apartheid laws and policy frameworks for emancipation of women are supposed to create an enabling environment for women, especially with regard to labour issues. However the situation with women and work in South Africa is still below set goals. Using the construction industry as context of study, an updated picture of women and work in the local context is presented. A purposive sample of literature related to women liberation especially in the work place, and women in construction in South Africa is utilised. Literature review is complimented with analysis of local labour statistics, which makes use of secondary data from South African national labour force surveys. Findings show that women in construction in the local context are still concentrated in non-professional and non-technical work types.

Keywords: Construction, development, employment, gender, women.

INTRODUCTION

Research interest for the paper concerns the effectiveness of the gender-positive environment created as one of the outcomes of South Africa's democracy of seventeen years. Specific focus is given to the employment situation of women in the local construction industry. Following from previous research work, an updated study exploring the highlighted issues further is presented.

South Africa has a history of strong racial and gender conflict, and oppression. Since 1994 the nation entered into a democratic era in which the collective impact of previous dispensations is still prevalent (Government Communication and Information System (GCIS), 2011). Gender main mainstreaming policies in relation to employment and promotion of women only came into existence after inception of

[1] obinna.ozumba@wits.ac.za
[2] chinemeozumba@yahoo.ca

democratic rule (The South African Department of Labour, 2010). Therefore it is arguable that apartheid era South Africa, had enabling environment for high occurrence of gender based discrimination in the work environment. It is also arguable, that gender mainstreaming interventions instituted in post-apartheid South Africa, would address inequalities of the past. Thus effectiveness of the new gender-positive environment could be measured through women empowerment. Critical areas include race and education, in relation to employment and promotion of women.

RELEVANT CONCEPTS IN THE STUDY

Theory discussed here centres around women liberation in Africa and South Africa in particular. Issues relating to Women employment are centred about the intersections of feminism, women and work, gender and development. Specific focus on women employment issues in the local construction industry also concern Human Resource Management (HRM) policies, legislations and implementation.

Feminism

History of Feminism is notable in Europe and America, where initiatives have been taken against marginalization of women since the nineteenth century. There have been three waves of feminism. Consequently the following issues have been addressed: women's rights to education, employment, property rights, women's suffrage, economic rights, as well as sexual and reproductive rights (Karl, 1995); social and legal norms that affect women (Rowbotham, 1996); ending institutionalised oppression of women; empowerment of women for participation in decision making at all levels of society; and transformation of society through women's participation and perspectives (Karl, 1995).

Gender and Development

The Gender and Development (GAD) concept emerged from the 1985 United Nations (UN) Women's Conference in Nairobi. GAD focused on issues of subordination in social relations between men and women (Pearson, 2000). The major outcome of GAD is the promotion of women's advancement nationally and internationally. The following events took place with landmark outcomes: world conference on Equality, Development and Peace in Mexico, 1975; the decade for Women and Development, 1976-1985; appraisal of the 1975 world action plan for women advancement in Copenhagen, 1980; International treaty on Convention on the Elimination of All forms of Discrimination Against Women (CEDAW) in September 1981 (UN, 1995); and the emergence of 'Forward Looking Strategies for the Advancement of Women' (FLS) in Nairobi, 1985 (Jahan, 1995). Furthermore the Beijing conference of 1995 resulted in a declaration, which addressed critical areas of discrimination against women including, education (Kvinna Till Kvinna Foundation, n.d.). The above mentioned developments have had positive impact on the advancement of women, with the emergence of new challenges. Research shows that the feminine footprint in the labour market has increased globally. However the increasing population of employed women experience poor work terms and conditions (United Nations Research Institute for Social Development (UNRISD), 2005). Possible inferences at this point include: that women are less paid; women are fewer in professional, technical and managerial types of work; and that women do not enjoy succession to higher levels of work or pay.

 ISBN: 978-1-84219-840-7 .

Women and Work

With regard to work, women's effort could be grouped into reproductive work, economically productive work, and community managing work. These groupings respectively refer to women's biological roles for children and family; work done in exchange for payment in cash or in kind; and the mostly voluntary or unpaid community management work. In contrast, most work undertaken by men for the general good is usually rewarded in some way (Moser, 1993). The suggestion here is that there are culturally embedded perspectives with regard to gender and labour. Furthermore there could be fundamental differences in perceptions and management of human resource across human cultures.

Human Resource Management

Human Resource Management (HRM) could be seen as influencing the employee population of an organisation, different from the organisation's ownership (Wojtkiewicz, 1985). More recently HRM is described as the procedure for achieving balance between growth and development for any organisation; and the same for its employees, within the organisation's capacity (Grobler et. al., 2006). HRM is essentially aimed at improving effectiveness of employees in an organisation (Heneman et. al., 1986). The process of HRM moves from policy to practice. As such policies are developed, interpreted and then implemented (Grobler et. al., 2006). The advent of globalisation has impacted the practice of HRM appreciably. Recent developments include global expansions of companies; mutual awareness of cultural differences; Asian economic growth; outsourcing of production to less developed countries; impact of information and communication technologies; labour issues such as leave allowances, remunerations and compensations (Friedman, 2007).

The South African Case

Since cultural peculiarities and history are strong influences on women and work; it is arguable that African countries such as South Africa have good grounds for women liberation issues. Across the African continent there are records of African women leaders of resistance movements, starting from the 7th century. Examples include the Berber Queen, Kachine of the Maghreb; 9th century Magajiyas of Daura; 16th century Queen Amina of Zazzau; and 19th century Nehanda of Zimbabwe. Moreover, early 20th Century has records of Igbo (Ibo) women leading resistance in the Aba women's riots (Oxford University Press 'OUP' blog, 2007; Net Industries, 2010; Trask, 2004). In South African history, prominent women activists include Charlotte Maxeke, Lillian Ngoyi, Albertina Sisulu, and Winnie Madikizela-Mandela (Mlambo-Ngcuka, 2006). Formal feminist movement in South Africa started with the 1990 Malibongwe conference in Holland, which birthed the 'Statement on the Emancipation of Women in South Africa'. This was followed by adoption of 'Women's Charter for Effective Equality' by Women's National Coalition in 1994 (African National Congress, n.d.). Local feminist efforts have since brought constitutional changes in the areas of gender equality and socio-economic rights (Hassim, 2005).

Apartheid South Africa, institutionalised gender based discrimination at the workplace. Denial of employment by legislation existed and promotion to management level was non-existent were employment occurred. The severity of such circumstances was felt more by racial definition (Bezuidenhout et. al., 2008). African

(black) women especially were corralled in forced settlements and forbidden from accessing education, and formal work or business (Meer, 1985; South African History online, n.d.a). The infamous Bantu education policy was a major tool for incapacitating the African (black) workforce (South African History online, n.d.b; Christie and Collins, 1982). However post-apartheid South Africa has seen the emergence of several legislations, strategies and interventions to empower women in the work place. There is the Act 66 of 1995 (labour relations act); Act 108 of 1996 (South African constitution Act); Act 75 of 1997 (Basic conditions of employment act and amendments 42/1996, 27/1998, 2/2002); and Act 97 of 1998 (skills development levies act). Complimentary legislations focus on health and safety, and workers' compensation for injuries and diseases (The South African Department of Labour, 2010). Despite such positive developments South Africa had poor global HRM rankings in the year 2000 (Grobler et. al., 2006). In response certain legislations have been amended, while new ones have been put into effect (Public Service Commission, 2006). Furthermore the government has instituted numerous programmes to address women employment, especially in the construction industry. However construction is still dominated by men, as shown by recent research (Didiza, 2008). In addition there are complimentary efforts by voluntary organisations towards levelling the playing field for women in construction. Despite such interventions, the figures remain low. Reasons proffered include discrimination in employments and promotions, and lack of support structures for female staff (Fielden et. al., 2001). Women made up 44.87% of the employed population in South Africa as at September 2009. However women in construction comprised only 13% (Statistics South Africa, 2009). Currently 31.20% of the women work force in South Africa is concentrated in the services industry. However construction, mining, utilities and transportation sectors, have low proportions of the women work force (Statistics South Africa, 2011). On the background of literature reviewed, and following from previous research, there is need for further investigations into the feminine footprint of the South African construction industry. For the purpose of the paper, update of the trend of employment is used as a backdrop for examining relationships between types of work, and race and education.

METHODOLOGY

To further update the existing work, more issues were interrogated, namely the trend of employment under types of work; and analysis of the current women employment situation, under types of work. Analysis was performed at a deeper level, considering formal and informal sectors of the South African construction industry. The South African Labour Force Surveys (LFS) data sets from Statistics South Africa, were utilised. Access was obtained through their online database, (www.statssa.gov.za/). Descriptive analysis is utilised at this stage of study. Evaluation of data consists of time series analysis, descriptive cross-sectional analysis, and regression. (Leedy and Ormond, 2010). By examining the trend, development of women employment in construction over time is ascertained and highlights are identified for cross-sectional analysis. The trend also shows indicators of the rate of response of the construction industry to issues and interventions highlighted in the literature review. From initial descriptive analysis, education and race are further investigated for relationship with employment status of women across formal and informal sectors of construction. The updated trend analysis was performed for the time frame of 2000 - 2011. Further detailed trend analysis showing women in various types of work within the

construction industry was performed for the time span of 2006 - 2011. The reduced scope in this case was due to limitations of data.

SUMMARY OF DATA ANALYSIS

There is general increment in the proportion of women employed, when compared with the men proportion. Hence there is long term trend of convergence, where the proportion of women increases steadily but minimally. The trend of convergence is more obvious in the formal sector of the industry. However the informal sector still demonstrates more volatility, as was the case in the previous research paper. The trend of women employment in the informal sector moves from convergence to divergence. In this case the proportion of women employed is declining in comparison to proportion of men. For types of work, analysis focused on senior official and management; professionals; technical and associate professionals; clerks; service works, shop and market sales people; skilled, craft and related trades; plant and machine operators and riggers; and elementary occupations. Of these work types, elementary occupations remain generally within the same range of 48% -60% women. Only women proportion of clerks and skilled / trade works show appreciable volatility over time. The most movements occurred between 2008 and 2010. The highest rise in proportion was recorded for clerks in 2009. Generally proportions of the higher level work types seem to be declining over time. In light of the above results, a cross-section of 2011 LFS data was evaluated. A majority (approximately 53%) of construction employees in elementary occupations are women. However only 14% of the women are employed in skilled crafts and trades. Other work types have less than 10% women proportion employed. Particularly, only 2% of the professionals are women. Senior and management positions have 7% women proportion, while technical and associate professionals have 5% women proportion. With regard to the relationship of women in types of work with education and race, education is the significant variable with a p-value of 0.009 and an appreciable coefficient of 1.28. When regressed separately, race seems to be significant with a p-value of 0.022, but a low coefficient of 0.47. Investigating educational level further shows that Africans (black) and Europeans (white) are at the extremes. The black women population group in construction have about 16000 people without formal education. White women make up 25.87% of tertiary educated women working in construction. More black women are found in primary and secondary education levels. Furthermore the distribution of educational levels seems to be between higher and lower level work types.

FINDINGS AND CONCLUSION

The paper represents excerpts from a wider research agenda. Limitations were due to the secondary nature of data. However results thus far enable deductions on which to progress in the research. With regard to the main thrust of inquiry, the significance of findings is in the following areas:

The trend analysis suggests that the gender-positive environment in post-apartheid South Africa has increased women employment in construction generally. While women employment has increased over time, the rate of increase suggests a very slow improvement. Secondly fluctuations occur more in the informal sector of the industry, while more women seem to be gaining employment in the formal sector. Thirdly while more women earn income from construction presently, the trend does not seem to yield much value for the women workforce, since most of the women are employed

in elementary occupations. Fourthly both race and education have strong relationships with types of work for women in construction. However education is the stronger predictor. Race being a predictor albeit reduced, confirms literature about South Africa's history. Other factors not analysed in the paper may be equally strong predictors. Furthermore, fewer women are employed in the managerial and professional work categories.

Findings at this stage raise the question of commitment on the part of the industry, in implementing government policies. Also there seems to be further reduction of racial barriers in employment, but a sub-optimal development in the educational status of the women. Similarly it is arguable that insignificant succession to higher levels of work is occurring for women in the formal sector, due to race and educational barriers. Traditionally race was the major dividing issue in South Africa. However it is directly linked to educational status and as such, access to higher level skills and more employment opportunities. Therefore the racial divide is still evident in the types of work for women in construction. Certain races dominate certain work types. Certain races seem to be better educated and skilled for higher level construction work types. It is also arguable that certain types of work in South African construction have become employment 'safe havens' or labour 'quarantine', for previously disadvantaged women in the country. The above deductions have been utilised in propositions for further research.

A CONTINGENT VALUATION MODEL FOR ESTABLISHING THE VIABILITY OF PRIVATE SECTOR INVESTMENT IN URBAN WATER PROJECTS

Austin .C. Otegbulu[1] and Funlola Famuyiwa

[1]*Dept. of Estate Management University of Lagos.*

ABSTRACT

The millennium development goal (MDG) for sustainable access to safe drinking water and sanitation presents an enormous financing challenge, particularly to many low-income countries. This paper therefore aims at establishing effective user demand for water services through willingness to pay (WTP) in order to encourage private sector participation in water service provision using Lagos metropolis as case study. Data is collected by means of structured question are to establish the level of user willingness to pay and averting expenditure for water services. Analysis was carried out with both descriptions and inferential statistics. Findings show that users' WTP is reasonable, out varies from location to location. The study also established that the most significant factors affecting demand are high cost of alternative source, high cost of consequential damages and economic importance. This will provide a good guide to private sector investors in tariff setting and investment sustainability.

Keywords**:** private sector sustainability, viability, water infrastructure, willingness to pay.

INTRODUCTION

Sub Saharan Africa as a whole is unlikely to meet the millennium development goal (MDG) for water supply. Coverage in urban areas has been declining as utilities have struggled to keep pace with population growth. In the rural areas, more than 40 percent of the population continues to rely on surface water (Foster and Brienceno-Garmendia 2010). The situation is not different in urban areas where most households still rely on boreholes, wells, and vended water. Water is very critical to urban lives as its welfare implication cannot be overstated. Infections, diarrhea and other serious water borne illnesses are leading causes of infant mortality and malnutrition. Their impact goes beyond health to the economic realm in the form of lost workdays and school absenteeism. According to Barnegree and Morella (2011) it is estimated that meeting the Millennium Development Goal (MDG) for access to safe water would produce an

[1] Austinotegbulu@yahoo.com

ISBN: 978-1-84219-840-7 .

economic benefit of US $3.1 billion (in 2000 dollars) in Africa, a gain realized by combination of time saving and health benefits.

In the face of these challenges, cities in less developed countries are growing at unprecedented rates. The various tiers of government are struggling to cope with the face of urbanization and there is ever increasing demand for water infrastructure services. It has become obvious that government alone cannot cope with the problem of infrastructure particularly water. There is therefore an urgent need to invite the private sector to participate in the provision of urban water services. Studies have shown that most urban dwellers purchase water at prices higher than that provided by public utility agencies. Government in developing countries including Nigeria have often subsidized water supply typically in an attempt to achieve social and health benefits for the low income households which constitutes majority of urban population (Montes De Oca, Bateman et.al, Tinch and Moffat 2004).In spite of this, the United Nations Development Program (1998) development report has called for subsidies to be phased out since all too often, they do not benefit those intended; the urban poor do not have any service at all, and do not receive the subsidy. The present end towards privatization is likely to end all such subsidies. In effect, if we want good water supply service, we have to pay for it. The private sector must establish affective demand before embarking on water project by eliciting user preferences and their willingness to pay for water provision. Willingness to pay for services will be much greater and the resource will then be used in ways that lead to increased satisfaction if infrastructure is built where there is sufficient demand for the services.

Over the years, government have been responsible for infrastructure provision by addressing the cost of building and maintaining water plants and network by collecting user fees, raising taxes, issuing bonds etc.

This is however characterized by shortages in capital funding and ever rising maintenance cost, lack of transparency and corruption. Tariffs are set to recover these expenditures but the revenue streams are insufficient coupled with resultant budget deficit due to underpricing and under collection.

The fundamental transactions whether concession or Public-Private Partnership (PPP) is that they provide a proven mechanism for government to alleviate the need for direct capital expenditure on new facilities while also potentially improving service provision. Generally the water sector reforms were composed of three components: decentralization, regulation and private sector participation. It is an integral part of the reform process. Many countries created national agencies for water, similar to the water services regulatory authority model of the United Kingdom.

Privatization of water infrastructure in sub-Saharan Africa is still emerging. Rather in response to growing appreciation of the problem of the traditional public enterprise model, many governments in Africa and elsewhere have attempted to improve the performance of state owned enterprises through performance contracts with public managers and or corporation.

ISBN: 978-1-84219-840-7 .

This study therefore aims at establishing effective demand for urban water infrastructure provision through user willingness to pay in order to encourage private sector participation in service provision using Lagos (Nigeria) Metropolis as case study.

Literature

Service delivery is the cornerstone of city governance and includes access to water, trash collection, wastewater etc. Financing of these services poses great challenges to different tiers of government in Nigeria. The reliability quality and cost efficiency in the provision of urban services are very central to the issue of governance. There is need for sustainability in infrastructure provision which requires; Cost recovery, Transparency, Stakeholder participation and Communication, Need assessment and willingness to pay and Accountability.

The governments have been unable to apply the above in urban governance and service provision. The way out of this situation is private sector participation in service provision.

Water infrastructure

In spite of the importance of water to man, it has remained scarce. Shortcomings in water supply in large urban areas of developing countries are a critical problem affecting millions of people, (WHO, 2002; Dublin, 1992 in Montes De Oca et al, 2004). Governments in developing countries have often subsidized water supplies typically in an attempt to achieve social and health benefits for the low income households, which constitute majority of urban population (Montes De Oca et al 2004). However, a perverse result can arise if the benefits of the subsidy go to high income households who achieve reliable services while poorer households have irregular and un-potable water supplies and may often purchase the water required from other unsubsidized informal or private sources.

The 2006 Human Development Report (HDR) stipulated a minimum of 20 liters of clean water a day for all as a human right, to check a growing water and sanitation crisis that causes the death of about two million children every year. According to the report, unclean water is greater threat to human security than violent conflict, across much of developing world.

It was revealed that each year, 1.8 million children die from diarrhea that could be prevented with access to clean water and toilets. In addition, 443 million school days are lost to water related illness, and almost 50% of all people in developing countries suffer at any given time from a health problem caused by a lack of water and poor sanitation. Unclean water and poor sanitation are directly implicated in the huge difference in life chance that separates children born in poor countries from children born in rich countries.

Most households, industries and real estate developers' in Lagos have to make provision for privately installed water infrastructure to meet their daily needs (Enendu, 2007; Lees and Anas, 1989). The poor may not be able to provide their own boreholes and therefore

ISBN: 978-1-84219-840-7 .

rely on supply from any affordable source. When it comes to clean water, the platform in many countries is that poor gets less, pay more, and bear the brunt of the human development cost associated with scarcity (UNDP,2006). In Lagos and most other parts of Nigeria, women and young girls carry a double burden of disadvantage since they are the ones who sacrifice their time and their education to collect water.

AVERTING EXPENDITURE

Mitigating expenditure and averting behavior

These approaches assess the value of non-marketed commodities such as cleaner air and water through the amount individuals are willing to pay for market goods and services to mitigate an environmental externality or to prevent a utility loss from environmental degradation or to change their behavior to acquire a greater environmental quality. It is the expenditure to avert or mitigate effect arising from reduction in quality of environmental assets (Garrod and Willis 2001, Callan and Thomas 1996, Otegbulu 2010). For example if water supply in an area is not regular, the consumer may resort to vended water supply as an alternative. Environmental values can sometimes be inferred from mitigatory expenditure or averting behavior.

Willingness to pay (WTP) for water infrastructure

A commonly applied approach for assessing WTP for improved water service is the contingent valuation method which involves a survey-based technique to directly elicit households' preferences (Montes De Oca and Bateman 2006, Otegbulu 2010, Mitchell and Carson 1989). The technique requires the construction of a contingent market through which correspondents may state their WTP for specified provision change in a particular good. When estimating WTP for water improvement within developing countries the scope test is complicated by the fact that income levels are correlated with current levels of supply ,such that those who would benefit most from a provision change to some specified level are those least able to pay for such changes.

Essential elements of the survey are description of environmental goods that are to be valued, description of the payment vehicle, and description of the hypothetical market. Describing the natural good include identifying all valuable attributes of the good. The payment vehicle pertains to how the money will be paid. One can pay for a good in cash any time it is used or by means of increased income tax. The description of the hypothetical market should include an identification of those who will provide and those who will pay for the improvement of the environmental good. It should be made clear that the payment is a collective action. Everybody else will also pay; otherwise, respondents may refuse to pay although they appreciate the good (Hoevengel, 1994; Mishra 1998, Desvousges et al, 1998; Freeman, 1993; Mitchell and Carson. 1989).

The valuation question can take several different forms. One is whether the question asks for respondents willingness to pay (WTP) for an environmental good, or their willingness to accept (WTAC) payment to forgo the good. Willingness to pay is the maximum sum of money a respondent would be willing to pay for an increase in an environmental amenity or to prevent degradation in one. Willingness to accept is the minimum sum of money respondents would require to forgo an improvement in an environmental amenity or to

ISBN: 978-1-84219-840-7 .

accept degradation in one. WTP takes as its reference point, the absence of the improvement while WTAC takes as its reference point the improvement. WTP is constrained by income while WTA is not (Freeman, 1993).

STUDY METHODOLOGY

Methodology

A CV survey questionnaire was designed to elicit information from households on their averting behavior, condition of service quality, willingness to pay for improved water supply preferred payment vehicle, and factors affecting demand.
Document on existing tariff structure was obtained from the Lagos Water Corporation.

The CV method usually values good which the respondents have experience in. The sample size is 1040 households spread over eight metropolitan local governments out of sixteen which constitutes the sample frame.

The local government for the study includes Kosofe, Eti-Osa, Alimosho, Ikeja, Mushin, Surulere, Apapa and Shomolu. Out of the 1040 questionnaires distributed 774 (77.4%) was returned and analyzed with the used of sample percentage, relative impact index and factor analysis.

WTP and averting expenditure will be compared with what households are currently paying for public utility water supply. Currently, block of flats pay₦500.00 per month, duplexes and detached houses pay₦800.00 per month while tenement rooms pay ₦1000.00 per room yearly. Public taps are paid by the local government authority.

RESULT

Respondent's characteristics

The respondents are mainly head or spouse of the household in their age is mostly above 20, while their average income is between ₦1,200,853 and ₦333,833.00 and most of the respondents have lived in the study area for more than 7 years which shows they have sufficient experience. Households in the study area prefer to pay for water through monthly bills or one off payment. Other sources of water supply include vended water, borehole, well water and rain water.

Table 1. Frequency of Pipe borne water supply

		Once a week	Twice per week	Thrice a week	Once a month	Twice a month	Total
Alimosho	Freq Count	9	24	26	4	5	68
	Percent	13.2	35.3	38.2	5.9	7.4	100%
Apapa	Freq Count	15	15	28	14		72
	Percent	20.8	20.8	38.9	19.4		100%

Eti-Osa	Freq Count	10	15	40	7	9	81
	Percent	12.3	18.5	49.4	8.6	11.1	100%
Ikeja	Freq Count	7	9	51	1		68
	Percent	10.3	13.2	75.0	1.5		100%
Kosofe	Freq Count	5	18	30	2	6	6
Percent	8.2	29.5			49.2	3.3	9.8	100%
Mainland	Freq Count	10	20	40	10		80
	Percent	12.5	25.5	50.0	12.5		100.0%
Mushin	Freq Count	12	23	30	7		72
	Percent	16.73	1.9	41.7	9.7		100%
Surulere	Freq Count	6	8	26	9		49
	Percent	12.2	28.6	81.6	18.4		100%

The responses from table 1. Shows that water supply is not very regular in most local government areas as majority of them have water supply only thrice a week. Others enjoy water supply once a week, twice a week, once a month or twice a month. In Alimosho local government 38.2% households have water supplied thrice a week while 35.3% have it twice a week. In Eti-Osa 49.4% of households have water supplied thrice a week while 75% of households also have water supplied thrice a week and 81.6% of households in Surulere local government, while 40% of households in Mainland local government enjoy water supply thrice a week.The frequency of supply cannot be said to be adequate. The water supply situation could influence consumer's priorities.

Table 2 .Mean monthly expenditure incurred alternative water supply

	Mean	Rank
Shomolu	₦ 2514	1
Kosofe	₦ 2031	2
Apapa	₦ 1800	3
Alimosho	₦ 1770	4
Ikeja	₦ 1604	5
Mushin	₦ 1446	6
Surulere	₦ 1438	7
Etiosa	₦1338	8

Table 3. Mean willingness to pay (WTP) for improved water supply

	Mean WTP (₦)	Rank
Apapa	2436	1
Shomolu	2394	2
Ikeja	2060	3
Eti Osa	2213	4
Surulere	18385	5
Kosofe	17936	6
Mushin	1688	7
Alimisho	1670	8

Source Field Survey 2009.

Table 2 shows the amount spent by households on alternative water supply on monthly basis. The highest expenditure is in Shomolu local government with a mean expenditure of (₦2,514.3) while Eti-Osa has the least mean expenditure of ₦1,338.8. This could form a basis for setting water tariff in the study area, when combined with WTP. The amount spent to abate the inconvenience of inadequate infrastructure provision can influence consumer preferences and what they will be willing to pay if there is improvement in water infrastructure provision. Eti -Osa has the lowest averting expenditure probably because they rely more on bore-holes and spend less on water vendors. The averting expenditure and willingness to pay could be used for tariff setting.

Data from Table 3 shows the amount of money households are willing to pay for improved water supply in the area. Apapa local government area has the highest mean WTP of ₦2436.6 while Alimosho had the least mean WTP of ₦1670.8. However it is noted that the results of WTP do not significantly relate to income in the study area. This could be attributed to the fact that

housholds feel reluctant to divulge their income for fear that the information could be used against them.

Table 4. Total variance experienced

Extraction method principal analysis

Source field survey 2008.

Where; Component 1=Household need, Component 2= Poor condition of existing one, Component 3= Due to its economic importance, Component 4= High cost of alternatives,

Component 5= Importance to business, Component 6= High cost of consequential damage, Component 7= Alternative not reliable and Component 8= Alternative not affordable.

In the table 4 above only the first three components have values of above 1(2.689, 1.206, and 1.206). These constitute the most significant factors. Factors 1,2,3 captured all the variance in the components.

Table 5. Parameter estimation of the multiple regression analysis of influence of demand.

Parameters	**B-Coefficients**	**Standard error**	**Better t-value**	**Sigf.**
B0	-36.607	24.491	-	- 4.87	0.001
b1	0.885	0.212	.773	4.99	0.001
b2	0.796	0.219	.701	4.01	0.001
b3	0.772	0.324	.693	3.92	0.002

R^2=0.721 F-value 6.875

Table 5 shows the regression analysis output and is used to develop a model. Regression analysis performed on variables in respect of user demand preferences to determine the extent of the influence of the tree most significant factors with eign value above 1 was used to develop the model is as represented below;

$Y= -36.607 + 0.885X_1 + 0.796X_2 + 0.772X_3 + 24.491$

Where Y = User demand preference; X_1 = High cost of alternative source; X_2 =High cost of consequential damage; X_3= Due to its economic importance.

The largest factor that influence willingness to pay/demand preferences is high cost of alternative source with R^2 of 0.88 followed by cost of consequential damage with R^2 of 0.79 and lastly, economic importance with R^2 of 0.77. The performance of the overall equation is good as indicated by R^2 (0.721) statistics which explains 72% of the total variation about user demand preferences and willingness to pay for water infrastructure and F - Value of (6.875).

Discussion and conclusion

From the studies, provision of water from the public mains is epileptic forcing residents to resort to self-help like use of well water, boreholes and vended water supply at a cost higher than that charged by public utilities. This could be inferred from the averting expenditure and willingness to pay for improved water supply. Both the averting expenditure and willingness to pay per month are higher than the monthly tariff. Most households expend money on both public water supply and water from informal sector. This is a right signal that at 100% increase in tariff for improved and regular water supply is affordable to residents of the study area. The result of the factors analysis indicates the most significant factors that influence demand for water in the study area.

THE ABILITY OF QUANTITY SURVEYORS IN LAGOS STATE, NIGERIA TO APPLY INFORMATION TECHNOLOGY

Oluwaseyi Ajayi[1], Bamidele Mafimidiwo[2] and Olubunmi Johnson[3]

[1,3] *Faculty of Environmental Science, University of Lagos, Department of Building, Akoka-Yaba, Lagos state, Nigeria*

[2]*School of Environmental Studies, University of Lagos, Department of Quantity Surveying, Yaba, Lagos state, Nigeria*

ABSTRACT

The role of information technology in every sector of an economy of a nation cannot be emphasized. It had played a major role in meet the need of every client at a faster and efficient manner. The purpose of this study is to see the extent of use of information technology by quantity surveyors in project delivery in Nigeria. A total of 100 questionnaires were distributed and 65 were returned and used for the analysis, given a response rate of 65% .The population consists of registered quantity surveyors from 2007 till date. It was obtained from the professional body institute (Nigerian Institute of Quantity Surveying-NIQS).The respondents were randomly selected from the sampling frame. Descriptive research was used for this study. The data was analysed using SPSS 17th edition via percentage, mean item score and ranking. The study shows that most quantity surveyors acquired the knowledge of IT by self taught and in most quantity surveying firms, IT is used for costing, hence it make it easy to retrieved all past document and in taking decision. In essence IT serves as cost library for quantity surveying firms. IT aid practicing quantity surveying firms in preparing approximate estimating and aid as a cost library

Keywords: Delivery, Information Technology (IT), Performance, Quantity Surveying, Services.

INTRODUCTION

According to Ang et al(1997) cited in Gaith et al(2009), Information technology(IT) is the technologies dedicated to information storage, processing and communication. This is made up of software, hardware and telecommunication which convert the raw data into information for speedy retrieval. IT plays a vital role in sustaining the growth of any business organisation especially construction industry which contribution to the nation economy cannot be quantified.

IT has helped in fast, efficient development and management of building deliveries in the built environment especially quantity surveying profession. It had made it

[1] seyiajayi@yahoo.com
[2] atinukebunmi@yahoo.com
[3] delemafimidiwo@yahoo.com

possible to organize complex construction process in quantity surveying and in construction industry as a whole in a logical manner that enhances project performance. According to Shar (2012),in their study on the application of 'specification manager' in Pakistan, it was realized that numerous software packages are used in UK construction industry in various field such as Architectural design, Civil Engineering, Quantity Surveying, programme of work, specification, valuation, marketing, financial and site management. IT therefore has positive impact in construction services in the various field of the industry and in capital investment.

In Australian, Sohal et al (1998) studied Australian companies and found that IT is positively correlated to organisation performance. According to the study of Valida et al (1994) in Malaysia, IT use and integration are higher in companies providing goods and services than those in manufacturing and distribution. While Mul et al (2002) cited in Gaith et al (2009) study, also in Malaysia realized the used of Internet as an important tool to the Malaysia companies. The use of internet had not been fully harnessed by the Malaysian companies. It was concluded that they should improve their infrastructure and employed computer staff. Pamulu and Bhuta (2004) opined in their study on Indonesian construction industry that IT had helped in achieving cost saving and adequate communication among stakeholders in the industry.

Most developing countries have been slow to adopt the use of IT in their construction industry due to the advantage of IT on the betterment of project performance .It therefore becomes necessary for developing countries especially Nigeria to take advantage of the IT by exploiting the various technology resources available to improve the processes of their building industry since the future growth will depend largely on improvement of human resources. This study is based on the ability of quantity surveyors in applying IT for project delivery.

LITERATURE REVIEW

IT can no longer be view as an enhancement to traditional business procedures but as an innovation agent that enables new and different alternatives in operation of business organisation. The use of IT in construction is extending beyond the boundary of piecemeal application for improving the efficiency of discrete operation of individual organizations. It could also be used in government agencies and professional institution.

Quantity surveyors are one of the stakeholder involved at the inception and construction stage of construction industry Their paramount function to the client cannot be over emphasize and also to other professional bodies in the industry. They are referred to as the cost accountant in the industry and so they are both management and technology oriented. Quantity surveyors have broad knowledge in design, engineering, economics, law and management (Alabi, 2009).Hence IT could be used by them in order to broaden their scope and deepen the extent of his services to clients, other stakeholders and the construction industry at large (EL-Rufai, 1992).

The common types of software used in construction include are word processing, spreadsheet, CAD and internet software (Oladapo, 2006).CAD is mostly used for design, drawing and presentation (Rivard,2000).Quantity surveyors use IT for preparing bills of quantities(BOQ), estimating, measurement and presentation.

There are others IT packages that are used by quantity surveyors. They include WinQS32, QS Plus2001,QsCAD,CATO and Masterbill (Wills et al,1994;Adetola,1998;Murray et al.,2001)It software enhance service delivery of quantity surveying firms by ensuring accuracy in estimating and final account.

Although quantity surveyors in Nigeria have embraced the used of IT but there are some lapses. Such lapses is due to lack of clear understanding of cost and economy and also lack of proper training of professional staff (Alabi,2009).Also unwillingness of the senior management to delegate responsibility to junior staff through training on the usage of the IT software.

A number of research survey related to IT in developing countries are limited (Pamulu and Bhuta, 2004).It is due to scarcity of IT professionals, inadequate physical and information infrastructure, social and cultural diversity and political barriers that modulate and distort competitive markets.

Weighing the advantages of IT, it becomes necessary that quantity surveying firms and the construction professional should avail themselves of the various tool provided by IT in order to improve the performance of their service delivery from inception to final completion.

RESEARCH METHODS

The research was conducted by an examination of relevant literature followed by administration of questionnaires to quantity surveying contracting organisation and consulting firms. The list of the quantity surveyors are obtained from the professional body of the institute (Nigerian Institute of Quantity Surveying) ,who are registered members from 2007-till date. The quantity surveyors were randomly selected from the obtained list. The questionnaire sought to know respondents' personal data and to obtain some other data such as mode of acquisition of computer literacy, level of use of computer packages, its constraints on the uses and the impact of computer on quantity surveying service delivery. The questionnaire used a five point likert scale to measure a range of opinion from "strongly disagree" to "strongly agree", "not used" to "most use". 100 copies of the prepared questionnaires were distributed, 65 completed copies were returned and used for the analysis. The average response rate to the questionnaires was 65%.This response rate is considered adequate as according to Ellhag and Boussabaine (1999), Idrus and Newman (2002) cited in Oladapo (2007). A descriptive research design is used for this study. The data were analysis using Social Statistic for Social Sciences (SPSS) package 17th edition. The statistic tools used are descriptive statistic via percentage, ranking and mean item score (MIS) was used to analyse the data using this formula

$$MIS = \frac{5n_5 + 4n_4 + 3n_3 + 2n_2 + n_1}{5(n_5 + n_4 + n_3 + n_2 + n_1)}$$

Where:

N_5=no of respondents with strongly agree; N_4= no of respondents with agree

N_3= no of respondents with neutral; N_2= no of respondents with disagree

N_1= no of respondents with strongly disagree

That is: 5-strongly agree, 4-agree, 3-neutral impact, 2-disagree, 1-strongly disagree

DATA ANALYSIS AND RESULTS

 ISBN: 978-1-84219-840-7 .

Background information

Table 1 shows that 54% of the respondents have been in quantity surveying firm for less than 5years while 31% of the respondents are in the firm for less than 10years and only 15% have been there for above 10years.They have educational qualification ranging from national diploma(15%),higher national diploma(29%),Bachelor of science(45%) to Master/doctorate(11%).It implies that the respondents are knowledgeable to fill the questionnaire and they have adequate background of quantity surveying firm.

In term of years of experience, most of the respondents have over 10years(39%) experience,12% of the respondents have over 20years in quantity surveying firms.48% of the respondents are corporate member of the institution and 16% are fellow member of the institution. It implies that the respondents have adequate professional background of the profession.45% of the respondents are computer literate for over 10years and just 8% are computer literate above 10years.38% acknowledge that they have been using computer for quantity surveying services in their firm for over 10years and 29% for less than 10years.

Table 1: Background information

Background information	Frequency	Percentage (%)

Above 10years	25	38
Total	65	100

Mode of acquisition of computer literacy

Table 2 presents the mode of acquisition of computer literacy by the respondents. Self taught using computer manuals is the most used method for acquiring computer knowledge by the respondents. Other modes of acquiring computer knowledge are in-service training given by employer, learnt at school and the least used is private instructor.

Table 2: Mode of acquisition of computer literacy

Acquisition of computer literacy	Mean	Rank
Self taught using computer manuals	4.89	1
In-service training given by employer	4.00	2
Learnt at school	3.65	3
Training by professional bodies(conferences, seminar)	3.45	4
Private instructor	2.67	5

1=not used, 2=least used, 3=little used, 4=used, 5=most used

Level of use of computer packages

40% of the respondents use computer packages for costing. It is due to the fact that the core business of quantity surveying firms is costing.22% used computer package for internet communication and 15% for word processing and scheduling. The least used computer package is for accounting and design (3%) as shown in table 3.

Table 3: Level of use of computer packages

Computer packages	Frequency	Percentage (%)
Word processing	10	15
Internet communication	15	22
Costing	26	40
Scheduling	10	15
Accounting	2	3
Design	2	3
Total	65	100

Application of computer on quantity surveying practicing firms

Respondents strongly agree that ease of retrieval of past project information has a high impact on the usage of computer on quantity surveying practicing firms. Other impacts of computer on quantity surveying service delivery are meeting deadlines, improve performance of work and interaction with clients and also facilitate decision making as presented in table 4. The respondents disagree that it could reduce reimbursable charges and increase the cost of maintaining computer.

Table 4: Impact of computers on quantity surveying service delivery

Variables	MIS	Rank
Enhance ease of retrieval of past project information	0.99	1
Enhances meeting deadlines	0.98	2
Improve performance of work and interaction with clients	0.96	3
Facilitate decision making	0.90	4
Increase staff productivity	0.90	4
Enhances ease of productions of project/contract document	0.80	6
Ease communication through internet	0.78	7
Ease coordination and integration of project information among stakeholders	0.75	8
Gives users competitive advantage	0.75	9
Reduces paperwork	0.66	10
Reduces reimbursable charges	0.46	11
Increase cost of maintaining computer	0.45	12

1=strongly disagree, 2=disagree, 3=neutral, 4=agree, 5=strongly agree

Constraints on the use of IT

From table 5 below, inadequate power supply is rank first by the respondents as a very strong constraint to the use of IT by quantity surveying firms. It is due to erratic power failure in Nigeria, whereby firms have to depend on their own source of supply of light. The cost of purchasing quantity surveying software for preparing

bills of quantities and lack of knowledge of the usage of the software are also constraints on the use of IT as identified by the respondents.

Table 5: Constraints to the use of IT by quantity surveyors

Constraints	**MIS**	**Rank**
Inadequate power supply	0.98	1
Cost of purchasing quantity surveying software for preparing bills of quantities(master bill)	0.95	2
Lack of knowledge/usage of quantity surveyors software	0.79	3
High cost of employing quantity surveyor instructor	0.70	4
Updating of quantity surveyors software	0.66	5
Virus attack	0.50	6
Personnel abuse of system	0.46	7

1=very weak, 2=weak, 3=moderately strong 4=strong, 5=very strong

CONCLUSION

This study shows that the application of IT on quantity surveying practicing firms cannot be quantified. IT ensures ease of retrieval of past information; hence serve as cost library for quantity firms. It also enhances the firms meeting deadlines and a better interaction with clients. IT had been used by this firm's mostly costing, internet communication and word processing. Although there have been some shortcoming in using the quantity surveying software, It is due to cost involved in acquiring the software, on adequate knowledge on the use of quantity surveying software and very few instructor to teach the professional on the usage of the software. The quantity surveyors function which are suppose to be computerized entail estimating, programme of work, taking off and billing are not sufficiently made available in the firms. Most of the quantity surveyors acquired computer knowledge through self training as shown from this study. It shows the lapses of computer educators in the field of quantity surveying in the various tertiary institutions. And where the educators are available, there are no sufficient computer packages and computer system to be used by students. It is also affected by erratic power failure in our campus which limit the constraints of the use of IT where intending quantity surveyors are suppose to acquired the skill on the use of IT.

ABSTRACT

The recent worldwide economy downturn has meant changes in Nigeria's dynamic business environment with less construction work available and competition among contractors. Contractors and Builders main focus during a recession should be affirmative and proactive. This study therefore assesses the survival strategies for construction contractors in order to remain viable in a depressed economy. To achieve these objectives, a field survey was conducted on a sample of 75 contracting firms by stratified random sampling. The survey was conducted with the aid of structured questionnaires and analysed with the aid of scientist package for social sciences. The result indicated that rising cost of construction materials and inadequate training of supervisory/technical is the major causes of failure in a depressed economy, and also difficulty in getting bank loan/difficulty in securing projects are the main effect of depressed economy on construction contractors. In conclusion the most effective strategies for survival for construction contractors are to build a sustainable construction using different materials and improving the required improvement in quality of work.

Keywords: Contractors Depressed Economy, Nigeria, Strategies, Survival.

INTRODUCTION

With the current global recession, the economy of most developing countries has been thrown into very serious problems. Adner and Sherif (2009) affirm that the construction industry has unique characteristics that sharply distinguish it from other sectors of the economy. It is fragmented, very sensitive to the economic cycles and political environment, and has significant high rate of business failure. Contractors who have built up their firms through years of hard work are facing the most severe depression in decades (Ganaway, 2009). The global depression has created a structural break in the global economy. Businesses thus need to reassess their strategies for operating a highly integrated global economy. According to Oyesola (2010), this is an understatement to say that the workers are operating in a depressed economy because the monthly pay cannot meet the needs of the workers. The overall effect of the depressed economy had worsened the conditions of the construction

[1] Seyiajayi71@yahoo.com

[3] delemafimidiwo@yahoo

contractors in the country. So many construction companies both indigenous and expatriate had been forced to close down or relocated while those in operative are cutting corners and subjecting workers to inhuman exploitative and oppressive conditions of working in the guise for quest to break even. It had lead to unemployment, inability to fulfil social obligation and retrenchment in order to down size thereby embarking on contract staff or outsourcing. It is all anti-labour practices that lower the esteem of workers. The pressure of Structural Adjustment Programmed (SAP) and globalization weakened the economy by increasing the number of people with low incomes, unemployment and poverty. Construction contractors therefore adopt various strategies in order to achieve the objectives of their firms and for continuity (Olaniyi, 2009). The study of Lim et al, (2010) on contractor strategies in Singapore in a prolonged recession shows that contractors bid for more projects within their resources and capabilities. Project management, material wastage, financial management on firm's cash flow, froze salaries of workers and retained profit for unforeseen circumstances are the various techniques used by construction contractors to survive in a depressed economy. However, times of crisis are also times of opportunity, such as businesses developing foresight to use the economic downturn to position for the next upswing.

2.0 Strategies for survival of Construction Contractors

Strategic planning is an essential function of top management in a construction company. This strategy is devised with a problem-solving approach of system analysis in the following stages: examination of the company's mission, a survey of the company's business environment, an analysis of the company resources, development of a strategy and the choice of optimal strategy (Warszawski, 1996). Strategies in the development of the construction capacity involve development, adoption and modification of construction policies to be employed on construction sites, the implementation of incentive schemes, the implementation of quality control procedures, and advancement of labour training programs.

Marketing of construction services requires a number of strategies according to the attributes of the type and nature of the service provided at any one point in time (El-Higzi, 2001). The construction industry as a service industry survives on goodwill and image laundering. An overview of the literature, which allies strategic marketing to successful performance, reveals two areas of concern: the definition of the company mission and the nature of strategic plans and objectives (McKee et al, 1989; Jaworski, et al, 2000).According to Ansoff (1989), the primary objective of survival for the construction firm is to secure a sustainable advantage in the market against its competition. The firm must be able to work out its survival techniques through strategy in the context of the overall competitive scene. To determine what drives the market and where to compete, it must be able to respond to environmental forces that influence the choice of the appropriate strategies.

The total volume of construction demands fluctuate as the nation develops and the survival techniques for the firm is to diversify to markets where the opportunities exist for responding to the dynamic environment. This is of critical importance, especially given the fluctuating nature of the construction markets (Teo and Runeson, 2001). Taking account of changes in the markets, construction firms need to learn appropriate survival techniques to gear themselves up for opening in new markets.

3.0 Research methods

A survey research design approach is adopted with the population comprising of project manager, Engineers, Builders, Quantity surveyor and Architects, all drawn from construction firms located in Lagos State. Judgmental sampling technique was used for this study and data were collected at one point in time through close ended self-administered questionnaire. A total of 75 questionnaires were administered to construction firms and 50 were returned. The average response rate to the questionnaires was 67%, this response rate is considered adequate according to Oladapo (2007). SPSS 17th edition was used to analyse the data collected via percentage, ranking and mean.

4.0 Results and analysis of data

Demographic information

Table 1 presents the demographic information of the respondents for this study, 26% of the respondents are Builders and Quantity Surveyors, 20% are Structural Engineers and 14% are Architect.24 (28%) of the respondents obtained Bachelor of Science degree (B.Sc.) as educational qualification and 26% are Master holders (M.Sc.) in their respective fields.20% is HND (Higher national diploma) holders and 2% are OND (Ordinary national diploma) holders. These shows that the respondents have adequate educational and professional knowledge of their profession and so are knowledgeable to fill the questionnaires. In respect of professional level, 27% are both member of Nigerian Institute of Builders (NIOB) and Nigerian Institute of Quantity Surveying (NIQS), 22% are member of Nigerian Society of Engineers (NSE) and 14% are members of Nigerian Institute of Architecture (NIA).

Survival strategies of construction contractors

The professionals were of the opinion that for a contracting firm to survive under a depressed economy, quality of the material is a fairly significant factor with a mean (3.12). It is followed by educating the craftsmen with a mean (2.98). Cut in profit to keep workforce and equipment working ranked third with mean (2.81) followed by Development of resourcing for finance and re-use of resources. Shedding expenses as necessary ranked 6th with mean (2.70).The least effective strategies for construction contractor's survival are reduced vacation time until things improve which ranked 18th with mean (1.85) and discounting ranked 19th with mean (1.83) as shown in table 2.

Effect of depressed economy on construction contractors

The ranked factors from one to six represent the most significant of all nineteen factors while the factors from seven to fourteen are significant for consideration. Difficulty in getting bank loan ranked first with Mean (4.24) followed by difficulty in securing project with mean (4.22) as presented in table 3. Delay in time of delivery of service ranked third with mean (4.08) and lack of capital ranked 4th with mean (4.06). Inadequacy in meeting client demand with mean (3.50) and diaporisation (Relocating outside the country) with mean score (3.10) are the least effect of depressed economy on construction contractors which ranked 18th and 19th respectively.

Table 3: Effects of a depressed economy on construction contractors

Survival strategies variables	N	SD	D	UD	A	SA	Mean	Rank
Difficulty in getting bank loan	50	0	1	6	23	20	4.24	1

5.0 Conclusion

This study shows that for construction contractors to survive in a depressed economy sustainability of construction using different materials is an important strategy to be used by the contractors in order to continue in business. It applies to both indigenous and expatriate contractors. The key to strategy under stress is discipline. Therefore the survival strategy should focus on segment that is resilient during the downturn. Other strategies as identified in this study are educating lower skilled workers, Cut in profit to keep workforce and equipment working, development of new financial solution, re-use of resources and shedding expenses as necessary. If the above stated actions are taken into consideration then the construction contractors business will be better and run smoothly. The depressed economy will have little or no effect on their survival. Effect of a depressed economy on construction contractors are difficulty in obtaining loans, delay, insufficient cash flow and lack of capital, but with the strategies being implemented the effect will not have a negative outcome on the performance of the contractors in such an economy.

TRANSACTIONAL COSTS ARCHITECTURE OF LIGHTING RETROFITS FOR SOUTH AFRICA'S RESIDENTIAL BUILDINGS

Kennedy Aduda[1] and Alfred Talukhaba[2]

[12]School of Construction Economics and Management, University of the Witwatersrand, Johannesburg, P. O. Private Bag X3, Wits. 2050, South Africa

ABSTRACT

South Africa faces apparent electricity energy poverty and has heavily invested in the promotion of energy efficiency measures in buildings. However, performance parameters in energy efficiency programmes for buildings in South Africa remain lacklustre and are indicative of an inability to achieve intended market transformation or resource acquisition. Worldwide studies agree that the electricity energy efficiency markets often experience prohibitory adoption costs commonly associated with market failures or crippling barriers. Oliver Williamson's 'transactional costs theory' supports state intervention as a way of correcting the perceived market failures or barriers. As a way of understanding the cost dynamics in electricity energy efficiency adoption, this study focused on unravelling transactional costs architecture for lighting retrofits in South Africa's residential buildings. Using a combination of interviews with industry players and documentary analysis the prevailing transactional costs architecture for lighting retrofits in South Africa's residential buildings was modelled. Suggestions were then made on appropriate intervention foci needed to reduce the adoption costs for lighting retrofits in South Africa's residential buildings.

Keywords: Energy efficiency, lighting retrofits, South Africa, transactional costs.

INTRODUCTION

Two main issues prominently plague South Africa's electricity supply industry. These are the impending electricity supply deficit (Eskom, 2008), and highly carbon intensive electricity (Department of Minerals and Energy, 2005). These twin issues are some of the drivers for energy efficiency in South Africa. This may explain massive investment in electricity energy efficiency by the National Energy Regulation of South Africa (NERSA) which committed R 5.44 billion for the years 2011-2013 on energy efficiency for programmes run by Eskom (Eskom, 2011). Also noted is the R544 million invested by Eskom in energy efficiency programmes against an annualized saving of 1 339GWh for the 2011 financial year (*ibid*). This translated to an average unit cost of 0.0004 R/kWh of *negawatts* without considering the time

[1] Kennedy.Aduda@wits.ac.za

value of investment. It is also noted that residential lighting initiatives accounted for over 56% of electricity savings; (*ibid*). So far, over 47 million free CFLs being distributed since inception in the 1990s thus making it world's largest.

At between 40-30% of primary energy consumption, buildings account for substantial portion of energy use (UNEP, 2007). In South Africa, residential buildings alone account for 17% of energy use (Department of Minerals and Energy *et. al.*, 2002). An earlier figure on total electricity demand in all metropolitan buildings was approximated at 27% (Anderson *et. al*, 1995). It is therefore no wonder that the reviewed energy efficiency strategy targets a 10% demand reduction in electricity use for residential buildings by 2015(Department of Minerals and Energy, 2008). This target is perfectly achievable if certain organisational and market issues are addressed. However two issues currently cast the performance of South Africa's energy efficiency programmes as marginal. First is the seemingly low annual primary resource acquisition of 354 MW from demand side management programme against an average unit cost of 0.0004 R/kWh of *negawatts* in the last financial year (Eskom, 2011). Second is the inconsistency in overall electricity primary resource acquisitions depicted by annual comparison of Eskom's demand side management programmes for the last 5 years (see Figure 1).

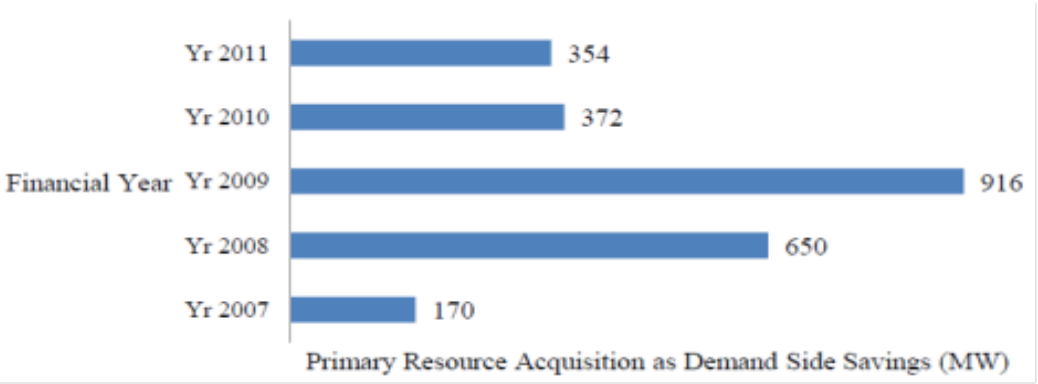

Figure 1: Primary electricity savings from demand side management energy efficiency programmes by Eskom; Eskom, 2011

The marginal performance could be related to certain market related issues best explained by transaction cost theory. To restate the transactional cost theory, it is posited that energy efficiency market transaction costs are prohibitive and warrants interventions to ensure minimisation (Golove and Eto, 1996). This paper attempts to outline the transactional cost architecture for lighting retrofits in South Africa's buildings. Borrowing from Mundaca *et al.* (2005), the following question is discussed:

> *What is the nature and scale of transactional costs of energy efficient lighting retrofits in South Africa?*

The importance of the paper is derived from the fact that greater understanding of transactional cost structure may ensure innovative intervention measures in the energy efficiency markets.

METHODOLOGY

Methodologies for the estimation of actual transactional costs for energy efficiency retrofitting or innovation adoptions remain enigmatic (Wang, 2003; McCann *et al*.,

2005). Mundaca and Neij (2006) outline three main methodologies for estimation of transactional costs, viz: 1) the use of seasoned informants' accounts such as those involved in programme design, decision making processes and lead adopters, 2) use of institutional data from agencies undertaking programmes and 3) use of labour and other time dependent costs emanating from field study. This paper uses a combination of in-depth interviews with key stakeholders and literature survey to explore the nature of transactional costs in South Africa's Eskom run lighting retrofits programme. The study utilised documents review and interview to gather information on lighting retrofits activities in programmes run by Eskom. Specifically respondents included members of the SAAE, Energy Service Companies (ESCOs) and residential end users. For the ESCOs programme key informants interview was conducted with two executive members of SAAE which oversees registration and pre-qualification issues and four other medium and senior employees of Eskom within demand side management programmes portfolio. For lighting retrofits, structured interviews were conducted with 43 home owners; two interviews with ESCOs and one interview was conducted with a CFLs distribution outlets' Executive. To complement interview sessions, documents on energy policy and demand side management were reviewed. The information gathered was then used to model transactional costs architecture for lighting retrofits in South Africa's residential buildings.

TRANSACTIONAL COSTS AND ENERGY EFFICIENCY PRACTICES

Two competing arguments exist with regards to energy efficiency market conceptualisation. On one hand is the postulation that perceives the energy efficiency market as fraught with barriers and in need of government intervention (Golove and Eto, 1996). On the other hand is the opinion that the energy efficiency market has a capacity to achieve the desired efficiencies and self-correction and as such government interference is unwelcomed in cases of temporal market failure (*ibid*). However, all schools of thoughts are unanimous that markets imperfections exists and hence the notion of market barrier or market failure. Bhattacharya (2011), Golove and Eto (1996) and Jaffe and Stavins (1994) all agree that the occurrence of market barriers or failures could be best explained using the concept of efficiency gap. Energy efficiency gap is the difference between the cost effective level of investment in energy efficiency based on engineering-economic analysis and the level of actual investment made (Bhattacharya, 2011; Golove and Eto, 1996 and Jaffe and Stavins, 1994). Sathaye and Murtishaw (2004) and Bhattacharyya (2011) further explains that the supply curve of conserved energy indicates the amount of energy that could be saved based on technical potential analysis on adoption of certain energy efficiency measures but this not often practical due to market barriers or failures.

Market intervention by the government is therefore sought so as to reduce efficiency gap. Market barriers include misplaced incentives, lack of access to financing, flaws in market structure, inappropriate pricing and regulation, gold plating and information related issues such as lack of information or misinformation (Golove and Eto, 1996; Sathaye and Bouille, 2001). As an example of manifestation of market barriers, it is noted that from the period of its introduction to date, CFLs have struggled to achieve marginal success in securing market share in the US (Sathaye and Murtishaw, 2004; Itron, 2004; Menanteau and Lefebvre, 2000). This is probably because of high initial cost, quality of illumination and an initial non availability in standard sizes (Sathaye

and Murtishaw, 2004; Itron, 2004; Menanteau and Lefebvre, 2000). The high initial cost is particularly related to the transaction costs as a result of setting up the roll-out network, administration, and performance of due financial and environmental diligence (Sathaye and Murtishaw, 2004). This forms the basis of discussion in this paper.

TRANSACTIONAL COST ARCHITECTURE FOR LIGHTING RETROFITS

An up to date understanding of transactional costs structure is of essence as it provides the basis of assessment and evaluation of market forecasts for energy efficiency improvements in addition to informing the formulation of measures targeted at elimination of transactional costs related market barriers (Mundaca and Neij, 2006). This is particularly emphasised by Painuly *et al.* (2003) who aver that the transactional costs constitute a significant part of market barriers to adoption of energy efficient practices and technologies. Thus where transactional costs are high, the energy savings may fail to achieve desired financial savings leading to longer payback periods which hamper adoption of energy efficient practices (Sanstad *et al*., 1994). Conceptually, transactional costs are those costs that arise during exchange of ownership rights of economic assets as a result of lack of information by the buyer (Hein and Blok, 1995). It is particularly noted that in energy efficiency demand side management programmes transactional costs manifests itself heavily during planning, implementation and monitoring and evaluation phases (Mundaca and Neij, 2006). However, for projects under the auspices of IPCC, other phases such as in issuance of tradable white certificates, trading in of the white certificate and redemption may ensue (*ibid*).

There is a consensus on the components of these costs. Hein and Blok (1995) identify these costs as those related to information, decision making, implementation and monitoring of retrofits. Valentová and Knápek (2011) specifically single these as those incurred by programme administration and subsidy recipient. The public administration based transactional costs are those related to design of the programme, technical expertise (engineering and legal based), programme administration, validation and processing of the programme, monitoring and verification and quantification of the results *(ibid*). The subsidy recipients incurs transactional costs relating to information search, initial negotiations, development of application, bank fees, negotiation of the contract, procurement, project validation and monitoring (*ibid*).

Hayashi *et al.* (2010) suggest a framework for that could be used to estimate CFL retrofits. Table 1 outline estimated model costs for 3 CFL retrofitting scenarios(1) the modest unit cost of CFL retrofitting for India, (2) High unit cost of CFL retrofitting for India and (3) Nominal unit cost of CFL retrofitting. Table 2 yields proportionate costs for the same scenarios.

Table 1: Estimated model costs for CFL retrofitting programmes, Hayashi *et al.* 2010

Table 2: % model costs for CFL retrofitting programmes, Hayashi *et al.* 2010

Cost Components		Modest Unit CFL Retrofitting Cost in India	High Unit CFL Retrofitting Cost in India (EUR)	Nominal Unit CFL Retrofitting Cost (EUR)
Fixed Cost	Programme Management-Upfront	0.38	0.38	0.38
	Programme Management-Annual	0.06	0.06	0.06
	Monitoring-Upfront	0.13	0.13	0.13
	Monitoring-Annual	0.01	0.01	0.01
	CDM fees-Upfront	0.09	0.09	0.09
	CDM fees-Annual	0.06	0.06	0.06
Variable costs	CFL Procurement	3.30	5.8	4.50
	CFL distribution &	3.80	5.0	0.51
	Other Costs	0.30	0.8	0.01
Total		8.13	12.33	5.75

It is instrumental to note that India's case appear most appropriate because of similarities in structure to the South Africa's lighting retrofit programme. In particular both programmes are based on rollout of the lighting fittings with minimal client's investment. As a result, the transactional costs categories are largely included in the

Cost Components	Modest Unit CFL Retrofitting Cost in India (%)	High Unit CFL Retrofitting Cost in India (%)	Nominal Unit CFL Retrofitting Cost (%)
Programme management costs	9%	5.9%	2%
CFL Procurement	40.6%	47.0%	78.3%
CFL distribution & retrofits	46.7%	40.6%	0.1%
Other Costs	3.7%	6.5%	0.1%

distribution and retrofitting category. It is indicated that for desired results in lighting retrofits, this category of costs must be less than 1% of the total costs (Hayashi *et al.,* 2010).

INTERVIEW RESULTS

Interview with end users

Structured interviews indicated that poor market penetration of lighting retrofits with % acknowledged use of the conventional incandescent bulbs, though majority (65 %) used CFL fittings. Only 19% used LED type fittings. However, the study did not inquire as to whether there was mix/cross cutting usage of all types of lighting fittings. Close to 60% and 50% were supplied with lighting retrofit fittings from the hardware outlets and local supermarket chains respectively. This indicated that substantial lighting retrofits were sponsored by electricity end users. A vast majority of end user indicated that electricity was very costly and agreed that lighting retrofitting were costly. This is indicative that the end users were aware of retrofitting benefits but initial costs were prohibitory. This was confirmed by over 90% of the respondents who also agreed that cost based incentives were needed to alleviate this phenomenon.

Interview with Energy Service Companies (ESCOs) AND ESKOM STAFF

The ESCOs were specifically perturbed by the fact that the financing and project approval processes were very lengthy and took between 2-3 years. This was further exacerbated by the fact that the financial procedures were unclear and were often

characterised by unfavourable payment terms. The ESCOs representatives also decried lack of information, conflicting interests amongst stakeholders and complicated contractual arrangements as hampering their operations. Also mentioned was worrying cases of inefficient management structures and lack of capacities amongst the ESCOs and Eskom. Eskom staff strongly lamented the long period of monitoring and evaluation and apparent diminished capacities amongst ESCOs.

Interview with Supplier

The suppliers indicated that they distributed the items top local supermarket outlets and that financial incentives were required to entrench energy efficiency. Apart from supplying the lighting fittings, the agency was also involved in educating the public on the benefits of their technologies. They were also lobbying for the ban of the traditional incandescent lighting fittings. According to the respondent awareness is created mainly by means of advertisements and training. The supplier ensures that all advertisements and training schemes are mainly based on energy efficiency and energy efficient retrofits. The supplier hopes to be the first company to initiate the much anticipated ban of the incandescent globe. It was also confirmed by the supplier that cost was an inhibiting factor to adoption of energy efficient lighting fittings. Also confirmed was that end users were concerned about lighting quality from the energy efficient lighting retrofit fittings.

Retail Costs

A survey of the market outlet chains (supermarkets and building hardware shops) indicated that the purchase cost per unit CFL lighting fittings was R30 (approximately EUR 5). LED lighting fittings retailed at R 180 (approximately EUR 30). Given the fact that interview with ESCOs indicated operational and administrative headaches and process related difficulties, the cost incurred on programme management was considerable and in general the transactional costs could be maximal. Further on, taken that South Africa does not manufacture CFLs, the costs associated with franchising, market set-up, testing, legal representation and agency issues may be on the higher side. This is very far from the ideal case recommended by Hayashi *et al. (*2010).

CONCLUSIONS

It is confirmed that transactional costs is a major hindrance to lighting retrofitting. It is particularly confirmed that the lengthy financial approval processes greatly slowed down participation into retrofitting programme by ESCOs. The interviews particularly confirm the observation by Mundaca and Neij (2006) that transactional costs are most prominent during planning, implementation and monitoring and evaluation phases.

RECOMMENDATIONS

As a way of alleviating prevailing transactional costs, emphasis should be made to hasten bureaucratic processes in the processing of documentation, monitoring, evaluation and verification process. This would ensure faster turnarounds for project financing apart from reducing the associated risks related to delays and uncertainty. In the end the transactional costs could be considerably reduced. Further studies are recommended to establish the actual transactional costs with greater certainty and accuracy.

AN EMPIRICAL ANALYSIS OF COST, INVESTMENT AND RETURNS ON SPENDING ON PREVENTATIVE HEALTH AND SAFETY BY CONSTRUCTION FIRMS

Andrew Oyen Arewa[1] and Peter Farrell[2]

[1, 2] *Faculty of Advanced Engineering and Sciences, University of Bolton, Bolton. BL3 5AB. UK*

ABSTRACT

There is debate amongst construction professionals about whether resources used to promote preventive health and safety in the workplace should be considered a cost or an investment. Money spent on preventative health and safety is distinguished from rectification expenditure, which is incurred after incidents or accidents arise. Various attempts to shed light on the debate by measuring returns on preventive health and safety spending remain elusive. Whilst there is some evidence that spending does yield returns, many professionals seem to doubt the validity of the measure of such returns. Thus, the research question; is spending on preventative health and safety a cost or an investment? Construction firms that consider spending on preventive health and safety as an investment may reap the benefits of cleaner sites, better motivated workers, better productivity and thus better profitability. The paper is based on a literature review and an appraisal of case studies of firms that have invested in preventive health and safety measures. It is a supplementary research and part of an ongoing PhD study that seeks to appraise the effects of investment in health and safety in the UK construction industry.

Key words: cost, health and safety, investment, returns.

INTRODUCTION

Ordinarily, spending on an item or services rendered is worthwhile as long as the benefits it brings exceed what was initially committed or spent. But the economics behind construction firms spending on preventive health and safety has been characterised by absurdity, confusion and elusiveness (Young, 2010). Whilst there is evidence that such spending does yield returns, there also seems to exist economic scepticism amongst many professionals in the construction industry on whether such spending be considered a cost or an investment.

Lee (2011) affirmed that, 'it is important for entrepreneurs to distinguish what elements of their endeavour be considered costs versus investments, even outside of sheer cash ... how one views a particular element changes drastically how one values and perceives its potential'. The value preposition attached to safety spending may influence the amount committed (Dorman, 2000). Bailey *et al* (1995) argued that,

[1] aa1gta@bolton.ac.uk

'committing organisation resources to improve health and safety is not an investment, because health and safety is a public good and desire which cannot be obtained through the normal market economy (return on investment) mechanism'. This assertion may be interpreted to mean that resources used to improve (preventive) health and safety cannot be measured based on normal market indices *per se*.

But economists and modernists are of the view that resources committed to health and safety is an investment, as long as such spending yields returns. For this reason, Hughes and Ferret (2007) claimed that 'safety is without doubt the most crucial investment that can be made, and the question is not what it costs, but what commitment to health and safety saves for organisations'. Moreover, the saying that 'health is wealth' ordinarily portrays resources committed into preventive health and safety as an investment. This can be corroborated by the Health and Safety Executive's (HSE 2011) assertion that 'investment in healthy people yields healthy businesses'.

Culyer *et al* (2008) argued that it is difficult to measure directly returns on resources committed into preventive health and safety; 'however there are basically three ends of returns to investment in occupational health and safety, namely: (i) such investment improves health and well-being, (ii) inherent value of greater security, and (iii) improved productivity'. This seems to justify the claim by Waterman (2012) that 'managing health and safety well is not a cost, it is an investment'.

LITERATURE REVIEW

There are no authoritative definitions of the terms, 'spending on preventive health and safety' and 'investment in health and safety'. However, the HSE (2008) asserts that, improving health and safety practice through commitment to safety is an investment because it enhances well being, productivity and profitability. The HSE (2008, 2009a) further highlights the following as investments in health and safety:

- ☐Commitment to safety budgets
- ☐Quality of risk assessments
- ☐Robustness/appraisal of safety policies and procedures
- ☐Commitment to safety plans, quality health and safety accounting statistics
- ☐Commitment to safety training
- ☐Engaging quality staff
- ☐Sub-contract vetting processes
- ☐Evidence of health and safety integration within the supply chain
- ☐Safe methods of working
- ☐Safeguarding of equipment
- ☐Commitment to use of PPE

Koper *et al* (2009) stressed that for spending on 'health and safety to be deemed as an investment, it should contribute significantly to performance aspects such as overcoming absenteeism, overall cost reduction, productivity and profitability.' Bailey *et al* (1995) argued that, 'ultimately investment should yield returns and can be measured using cost benefit analysis; because investment is often linked to numerous advantages which include process efficiencies, reduced cost and staff retention.'

The difference between cost, investment and return from spending on preventive health and safety

According to Lee (2011) 'there is significant difference between cost and investment'. Cost is a reference to the total money, time and resources associated with a purchase,

activity or service rendered,' and 'an investment is a reference to the use of money for future profitability'. Lucy (2009) argued that, it is somewhat difficult to distinguish between characteristics of a cost and an investment. However, using the q theory economic model put forward by Abel and Enerly (2002) which states that, 'optimal investment is dependent on both expected returns and costs of capital', attempt is made to differentiate between characteristics of cost and investment as illustrated below:

Difference between cost and investment using q theory economic model

Characteristics of cost	Characteristics of investment
☐ Cost is fully identified with product or services	☐ Investment is synonymous to commitment or deals that yield return
☐ Cost does not mean the same thing under all circumstances	☐ Under normal circumstance investment should yield return
☐ Cost of item may not be true, exact or the accurate amount paid for a product or service	☐ Investment is often driven by intention to make profit
☐ The composition of what constitutes cost differs under different circumstances	☐ Investment compositions are usually well spelt out, unlike cost that differs under different situations
☐ Different methods are often used to ascertain what constitutes a cost	☐ In most cases, it is market forces that control the outcome of normal investment
☐ Cost varies with time, volume, method or purpose	☐ Investment is synonymous to future purpose (gain)
☐ Cost is expenditure which may be actual or estimated, direct or indirect and should be related to a job, product, process or service	☐ Investment can be direct and indirect. It may be linked to training and development of product and services
☐ Customarily, to some extent cost has the traits of been subject to control	☐ In an ideal situation, investment should help reduce cost
☐ Cost is the opposite of revenue	☐ Divestment is the opposite of investment
☐ Cost must not necessarily yield return	☐ Most investment is valuable
☐ Investors usually minimise costs in order to maximise outputs.	☐ Investor's need to invest is usually influenced by 'pay-back time' and yield (returns)

Investments usually have more risk involved, but also could lead to more profitability (or reward) in the long run. Good investments should yield returns and are often driven by intentions to make profit. Bradley (2011) asserted that the performance measure used to evaluate the efficiency of an investment is often referred to as 'return on investment' (ROI). To calculate ROI, the benefit of an investment is divided by the cost of the investment; the result is expressed as a percentage or a ratio using the following formula:

$$\frac{\text{Gross income - Cost of investment}}{\text{Cost of investment}} \text{ X } 100$$

Additional economic measures such as pay-back time, which is the length of time required to recover the cost of an investment can also be used to determined effectiveness of an investment. Arguably, it is relatively difficult to use these economic models to calculate return based on investment or spending on preventive health and safety, because of the non-ring fenced nature of such expenses. For

instance, in practice money allocated for preventive health and safety in construction projects can be spent on diverse activities such as provision of scaffold, staff safety training, site security, cleaning of sites and hygiene facilities. Therefore, it is difficult to 'pin down' spending on preventive health and safety to a particular project cost centre nor can it be used effectively to measure ROI or pay-back time on commitment to health and safety. Perhaps, this may have informed thinking of the Royal Institution of Chartered Surveyors (RICS) not to include in its standard methods of measurement (SMM), pricing of health and safety activities as a stand-alone or separate item. Nevertheless, it should be mentioned that construction contractors do have bespoke means of adding money to preliminary items in Bills of Quantities, to allow for preventive health and safety in construction projects.

Hence, Culyer *et al* (2008) is of the view that, the challenges of not having appropriate economic models that can be used to measure accurately returns on spending on preventive health and safety using quantitative measurements may have contribute significantly to the difficulties associated with ascertaining whether spending on preventive health and safety is a cost or an investment. In this regard, the Occupational Health and Safety Administration (OSHA 2009) claimed that the economics behind spending on preventive health and safety is contentious, due to imprecise measurement and different viewpoints on whether such spending is a cost or an investment.

Dorman (2000) affirmed that 'expenditure used to improve working conditions is an investment in a strict economic sense; it is cost borne in earlier periods in order to reap benefits in later times'. On the other hand, it may be deemed inappropriate to consider spending on preventive health and safety using normal market investment parameters; because in terms of financing an investment, the loans from which normal market investments are made are usually collateralised by the assets the investment purchases or produces, such as equipment, material, patents and stocks of finished and part-finished goods. But the main asset under consideration in term of commitment to health and safety is human capital and workers cannot be offered as collateral. Firms do not actually own their workers, of course; they only rent them. As a result, all investments in human capital, including commitment to health and safety, are likely to be subject to adverse discrimination in financial markets (Koper *et al*, 2009). Thus, Dorman (2000: 9) in an articulate analysis acknowledged that 'investment in occupational health and safety has certain deficiencies that cause problems in the process of economic evaluation. These deficiencies (unequal distribution of costs, benefits, problem with perception and quantification) lead to lower levels of prevention than economically feasible, even at the enterprise level.'

In this regard, Culyer *et al* (2008) subsequently affirmed that the measure of commitment to health and safety against return or organisational profitability remains a challenge to the study of health and safety economics. This inherent difficulty seem to inspired most literature to base economic measurement of commitment to health and safety solely on cost benefit analysis, with little or no attempt to measure investment in health and safety directly with organisational profitability. The most recent study regarding cost benefit analysis on commitment to preventive health and safety was conducted by the International Social Security Association (ISSA 2011) which stated that 'the goal of prevention accounting is to calculate the microeconomic effects of occupational health and safety in terms of qualitative and quantitative metrics ... achieved by developing a cost benefit analysis ... using an ordinal scale that is suitable for qualitative observations', as illustrated in table 1.

Table 1: Prevention costs and benefits for companies; adapted from ISSA (2011)

Prevention costs (for companies). Value in EUR per employee per year		**Prevention benefit (for companies). Value in EUR per employee per year**	
Personal protective equipment	168	Cost savings through prevention of disruptions	566
Guidance on safety technology and company medical support	278	Cost savings through prevention of wastage and reduction of time spent on catching up after disruptions	414
Specific prevention training measures	141	Added value generated by increased employee motivation and satisfaction	632
Preventive medical check-ups	58	Added value generated by sustained focus on quality and better quality of products	441
Organisational costs	293	Added value generated by product innovations	254
Investment costs	274	Added value generated by better corporate image	632
Set-up costs	123		
Total costs	1,334	Total benefit	2,940
Cost-benefit on return of ROS ratio: 1:2.2.			

METHODOLOGY

The study research methodology is based on a literature review and an appraisal of eighteen case studies which illustrate various levels of commitment to spending on preventive health and safety; they are taken from information obtained from a HSE data base (HSE 2009a and 2009b). Details of seven out of the eighteen case studies are presented. Four are SMEs and three considered as large firms, as illustrated in table 2. Detailed analysis from data obtained shows that, commitment to health and safety yields returns that includes cost reduction, increased production, increased efficiency, improvement in equipment reliability, enhancement in worker trust and reduction in Accident Frequency Rates (AFRs).

FINDINGS

Findings from these case studies provide further evidence that resources committed to preventive health and safety are intertwined with other production activities and hence there are diverse returns on investment in safety (ROIS). Furthermore, findings from this study show that, the need to invest in preventive health and safety is meaningful to both large construction firms and also SMEs. It also suggests that, SMEs that invest in safety measures tend to have better savings from insurance premiums compared to large companies. This therefore means that, lack of commitment to safety can lead to negative safety image with the tendency to increase SMEs insurance premium.

Table 2: Investment in health and safety and return on investment analysis

	Name of companies	**Nature of business/No. Of employee**	**Nature of investment in safety**	**Approximate cost of investment in safety (£)**	**Gain from investment in safety/annual (£)**	**Return on investment in safety(ROIS)**
1	Data Scaffolding Services Ltd - UK	Construction - NoE 8	Employment of an external safety advisor and investment in high quality scaffolding	30,400	Saved approx. 21,000 from reduction in insurance premiums and others benefits	60% saving on insurance premium and increase in production efficiency
2	Ibstock Brick Ltd - Sussex, UK	Production of bricks - NoE 50	Investment in safety training and equipment	270,000	Saved approx. 20,000 quarterly and other benefits	25% reduction in days lost and increase of 1.5% in brick production
3	Dolphine painters. Dorset, UK	Construction internal finishes - NoE 20	Investment in new equipment, altering existing equipment and staff training	£5,000	15% reduction in overall operation costs and other benefits	15% reduction in operating costs. No employer liability claims
4	Huntsmans Quarries Ltd, Gloucestershire, UK	Construction - NoE 40	Training of staff and invested in staff welfare	£270,000	Saved approx. 20,000; increase in production and other benefits	5% increase in productivity and reduction of employer liability costs by 30%
5	Birse Rail Ltd, UK	Railway Construction - NoE 800	Invested in safety training and equipments	£135,000	Saved 16,200 per annum from increased efficiency and other benefits	69% reduction in AFRs from 0.64 (2001) to 0.20 (2002) per 100 hours worked
6	Edmund Nuttall Ltd, Wales and Scotland	Civil engineering Construction - NoE 2,500	Training and equipments	£92,000	Saved approx. 15,640 monthly from workers' absenteeism	Staff turnover reduced from 62% in 1999 to 33% in 2002
7	Wilson James, Essex, UK	Construction - NoE 500	Invested in worker well-being	150,000	Saved approx.14,000 per annum from insurance, and other remedial safety costs	Reduction in lost time, workers felt valued, gained worker trust

DISCUSSION

Motivating factors for spending money on health and safety are fear of the law, fear of being sued, fear of negative publicity and potentially higher insurance costs. The issue is not therefore whether expenditure on health and safety is implicitly made to secure a financial return, but whether this expenditure, albeit initiated to ensure compliance with the law, invokes spin-off into other spheres of business practice (such as cleaner sites) that consequently leads to enhanced profitability. Findings from this study indicate that commitment (investment) in preventive health and safety is good business (HSE 2008). However, the financial benefit in terms of organisational profitability emanating from investment in preventive safety practice appears to be intangible and difficult to measure. Also it could be argued that, the non-ring fenced nature of health and safety expenses used to provide preventive health and safety seems to exacerbate difficulties in establishing the relationship between costs, investment and returns on preventive health and safety paradigms. However, there is need to advance research on the role of organisations' commitments to health and safety and develop a sound business case for commitment (investment) in health and safety with regard to organisation's success (profitability).

CONCLUSION

The general view about spending on preventive health and safety seem to portray such expenses as an investment; that is, returns on investment are not considered as a factor when decisions are made about whether spending on health and safety should proceed. From the point of view of quantity surveyors or estimators, spending on preventive safety is arguably deemed as a cost, since contractors include money in tenders to take care of spending on preventive health and safety without being able to measure tangible financial returns. On the other hand, it is argued that the amount budgeted and spent on preventive safety may be used as an indicator of the commitment of organisations to health and safety, and such spending can be used as a parameter to determine the degree of safety in organisations.

Finally, it seems that in accounting terms, it is not appropriate to classify preventative health and safety expenditure as an investment. However, retaining the term 'investment' may be a useful semantic tool to be used to lever managers to spend as much money on health and safety as is reasonable. In all, what seems to be clear is that organisations that are committed to spending on preventive health and safety do reap numerous and varied returns, with the possibility of boosting overall productivity and profitability. Future work will seek to correlate investment by companies in health and safety best practice with profitability reported in externally reported annual accounts.

FIRE SAFETY IN BUILDING USAGE CONVERSION IN JOHANNESBURG, SOUTH AFRICA

Aghaegbuna Ozumba

[1]*School of Construction Economics and Management, EBE Faculty, University of the Witwatersrand, Johannesburg 2050, South Africa*

ABSTRACT

Conversion of existing buildings from one type of usage to another inevitably has a wide range of implications such as whole building performance, energy efficiency and fire safety. Results of a pilot study to address fire safety issues in building usage conversion are presented in the paper. The study is focused on fire safety issues related to the current trend of converting older commercial buildings to residential use, in Johannesburg South Africa. A select number of issues were investigated in relation to fire safety and protection of such buildings. Issues considered include provisions for fire protection; effectiveness of approval process; compliance inspection, supervision and monitoring; new occupancy; depth of fire safety awareness and training by relevant parties. The research objective essentially addresses fire safety implications of occupancy change and conversion of building spaces and sub-systems; in relation to current practice in South Africa. Findings thus far suggest existence of lapses in design provisions for fire safety; lapses in the approval process and capacity issues with existing monitoring systems. Other areas highlighted include fire safety equipping of buildings; training and awareness of facility management and occupants.

Keywords: building conversion, compliance, fire safety, monitoring, regulations.

INTRODUCTION

The research interest here is in fire issues about conversion of building usage in South Africa. The study represents a combination of concepts from building science, building performance, fire safety and protection in buildings, building regulations, housing, and adaptive re-use of buildings. Conversion of buildings from one type of use to another, should comply with regulations for upgrade of buildings. Such codes emphasise fire safety issues. Other aspects of the building are also expected to comply with relevant codes. In addition alterations are expected to result in improvements of fire safety provisions in such buildings. Compliance approval for such provisions emanates from regulatory bodies (Powell, 1990). Building conversion refers to the recycling or alteration of a building structure to suit a different purpose other than the original designed usage. Building usage conversion is a trend in the world, where it is mainly employed for revitalisation of cities. Examples include conversion of office

[1] obinna.ozumba@wits.ac.za

 ISBN: 978-1-84219-840-7 .

buildings to residential use (Cook and Hall, 1997). Conversion of buildings plays an important role in helping to meet growing demands for residential accommodation. It is also considered an adaptive re-use, which is a sustainable option for promoting urban growth. In addition conversion increases the number of households living in city centres. Such increase is considered a strong factor in realising social, economic and environmental development goals (National Centre for Environmental Health, 2000). However in converting buildings, non-compliance to fire safety is addressed through improvements. Thus such facilities should have compliance approval (Powell, 1990). Importance of compliance is symbolised by research showing that building conversion is a major cause of fire outbreak (Barlow and Gann, 1996). Fire safety and protection in buildings concerns the prevention and reduction of fire hazards such as death, injury, or damage to property. Fire protection increases the chances of survival for users, in the event of fire (Blossom, 2002). Consequently codes, regulations and ordinances have been developed over time to guide provisions for fire protection in buildings. Such provisions vary according to climatic zones, types and location of buildings, and interior spaces. It also involves the use of both passive and active designs, and artificial components (Ogus, 2004). Therefore fire safety status of converted buildings should be a major consideration, in re-design and implementation. However, fire outbreak in converted buildings remains a key barrier to expected business growth. Research suggests a need to address fire implications of usage conversion in building regulations of most countries. Addressing fire safety issues in this case should ultimately achieve full compliance of such buildings (Millward, 1994).

USAGE CONVERSION AND FIRE IN BUILDINGS

Building usage conversion, especially the conversion of office buildings to living spaces (residential buildings) has been in occurrence since the 1970s. It has been viewed as a cost-effective way of renovating and re-using old building stock (Homebuilding and Renovating, 1999). Essentially building conversion has been an answer to the high vacancy rates of office buildings in cities within places such as the Netherlands, Germany and UK. Thus it is viewed as prudent to apply adaptive re-use by converting commercial buildings to residential purposes or mixed use. Usage conversion brings sustainability to the context. It affords savings in construction time, re-use of materials, and reduction of impact on natural resources (Hilde and Van der Voordt, 2007). In addition it is used to address shortage of residential building supply (Millward, 1994). Furthermore conversion is preferred on economic grounds, to erecting new structures (Yoshimura, 2000). In France and UK vacant offices and other facilities have been converted to other uses, especially residential (Feinstein, 1995). Older office and public buildings which are converted, hardly comply with modern fire protection standards. Areas of non-compliance include unsuitable stairway design, narrow or dead-end corridors, narrow doors, wrong swinging doors, and unrated materials. Such issues need to be addressed in relation to local codes, for approval and occupation of converted buildings. Adaptations made necessary by such needs present challenges to stakeholders such as owners, builders, architects and other consultants (Fall, 1997). Research shows examples of severe fire outbreaks which are linked to building conversion in cities such as London, Toronto, Sydney, and Virginia in the USA (Barlow and Gann, 1996; Millward, 1994).

 ISBN: 978-1-84219-840-7 .

Fire safety, protection and compliance in buildings

Principles of fire protection in buildings refer to active, passive and structural measures; which are incorporated in planning and design, and subsequently built into the structure. The aim of fire protection is to arrest and limit consequences of fire outbreak, and protect the building structure, contents and occupants. Fire protection in buildings addresses fire spread control, fire escape and fire-fighting access (Stollard and Abrahams, 1999). In so doing, fire behaviour of building materials utilised and contents of the building are considered. Areas of scrutiny include ignitability, combustibility, flammability, potential heat production level, smoke and combustion gases production potential, surface spread of flame, volatility of the material aflame, and smoothness and density of the material. In addition fire resistance of building elements are also considered. Stability, integrity and insulation capacity of each element are used for rating each element or component (Shields, and Silcock, 1978). Other important factors include fire detection and extinction (Yatim and Harris, 2005). Furthermore there is need for awareness, fire safety consciousness and training of occupants (Stollard and Abrahams, 1999). It is arguable then that such complex considerations are necessary, especially when a facility is converted from one usage type to another.

Usage conversion and fire safety of buildings in Johannesburg

Building conversion in Johannesburg is a trend that seems to have started in the late 1980s and early 1990s (Health, Housing and Urbanisation Directorate, 1992). It is reported as a part consequence of housing problems. Such housing issues are traceable to the housing needs of the urban poor in most developing countries (Gilbert, 2000). Rapid increase in conversion of commercial and industrial buildings to residential use has followed inception of democracy in South Africa. Conditions of such buildings are known to be sub-standard and hazardous to life, with overcrowding (Crankshaw and Gilbert, 2000). In addition the city has a large collection of mostly commercial and old building stock. Prolonging their life and usefulness usually requires modifications; some of which are aimed at bringing fire protection provisions up to prevailing standards (Richardson, 2007). In the City of Johannesburg; vacancy, rise in vandalism, structural decay, blight and devaluation of buildings constitute economic and social reasons for usage conversion (Accordino and Johnson, 2002). Thus building conversion has continued, with existing projects and planned ones running into multi-billion Rands collectively (Fraser, 2007). Opportunities and incentives to convert buildings exist in the form of relaxed zoning and property tax reductions. While such developments benefit stakeholders in the short term; the resultant overpopulation increases risk of fire among others (James, 2010). Building conversion is said to increase potential for slow transition within exit stairs. It has also been linked with difficulties in launching both exterior and interior fire fighting due to poor access (Fernandez, 2001). Other possibilities include obstruction of emergency routes in the course of occupancy and non-compliance in placement of fire safety signs (Richard and Sarah, 1981). Further challenges include the occupants, especially with regard to behavioural patterns of different people in fire emergencies (Colonna, 2001). Furthermore inspection and approvals by fire protection authorities are necessary for plans relating to all aspects of the building. The process includes monitoring of the project and post-renovation inspection, prior to issuance of fitness certificates (Butcher and Parnell, 1979). However there are barriers to effectiveness in enforcement of regulations, such as shortage of skills, administrative conflicts, and corruption (Listokin and Hattis, 2005).

Considering the discourse thus far, the trend of building conversion in the city of Johannesburg South Africa, poses the risk of fire incidents in the city. On this background, the research questions standards and provisions for fire protection in such city buildings; enforcement of regulations and occupancy implications. Thus a pilot study was designed to investigate fire safety issues in converting commercial buildings to residential use in the context of Johannesburg, South Africa.

METHODOLOGY

Considering findings from literature, and within the scope of study; there was need for the following: to review the fire safety requirements and provisions in the South African Bureau of Standard (SABS 10400), for converted buildings; to compare fire safety standards for commercial buildings with residential buildings; to examine the role of building inspectors and barriers to their effectiveness; and to examine fire safety awareness, training and compliance, of facility managers and occupants. In addition the following constructs were explored: Provision of fire protection in converted buildings; regulation and enforcement of fire safety compliance in the conversion of buildings; and awareness and training, with regard to fire safety implications of converted buildings. Responses to survey questionnaire and interviews are used to explore constructs. A combined approach was adopted for data collection and analysis, essentially employing interpretive and descriptive approaches (Creswell, 2003). Furthermore, since the study is focused primarily on buildings which were linked to various stakeholders; a considerable sample of buildings was utilised. Information could then be gathered from various sources to achieve a measure of validation and triangulation. Techniques utilised were documentary analysis, field observation, use of questionnaire and interview (Creswell, 2003).

DATA ANALYSIS AND FINDINGS

Ten (10) multi-storey buildings converted from commercial to residential use within Johannesburg city were initially selected. Based on willingness of occupants to participate, eight (8) buildings were eventually utilised for the study. Out of 120 questionnaires distributed equally, 93 were completed and returned; giving a response rate of 77.5% = (93/120 x 100). In addition interviews were conducted with facility managers of the eight buildings studied. Furthermore ten (10) members of the Johannesburg fire department were interviewed according to their divisions. The list includes the director, station commander, inspectors, the fire fighting team, and head of building team. Field observations were also performed on the eight buildings for validation of data. Descriptive statistics was used for the preliminary analysis presented in the paper. Proportions of respondents in the form of percentages and averages of percentages are used to describe analysis results. Summary of analysis and findings are presented in narrative form.

Results of exploring constructs

Under provision of fire protection in converted buildings, which was explored with facility managers and occupants; a 63.5% average of respondents indicated poor conditions in their buildings. For regulation and enforcement of fire safety compliance; while the fire department claims to be performing their duty, 63% of responding occupants indicated that inspections do not occur. With regard to awareness and training for fire safety; 100% of respondents (facility managers and occupants), indicated no occurrence. Furthermore 100% of facility managers and 77%

average of occupants did not demonstrate understanding of required fire safety compliance for converted buildings. However 75% of facility managers and 61% of occupants have observed fire outbreak on their buildings. In addition 75% of both classes of respondents indicate that occurring fire outbreaks were severe, causing injury to users.

Results according to sources of data

With regard to the local regulations (SABS 10400 of 1990); express provisions for fire safety and protection in converted buildings does not exist. The only guide is in the form of classifications used to direct implementation for peculiar building and occupancy types. Buildings are classified according to various occupancy types, with different fire hazard categorisations. While occupancy types range from class (A) through class (J), fire hazard categories range from low to moderate and high. In the absence of specific codes for the peculiarity of building conversion, the city of Johannesburg has by-laws for fire safety provisions in such buildings. However, only fire fighting equipment, escape routes and structural integrity are provided for in the by-laws. The approval process consists of submission of plans and drawings of conversion work, which are crosschecked for the stated provisions. Converted buildings which satisfy above mentioned requirements are issued certificates of compliance. However compliance needs to be enforced by the city fire department. The legal frame work for controls provides for regular inspections to check for any non-compliance that poses fire threats. Clearance certificates are issued when the conditions are met while legal action is instituted for non-compliance.

The fire department is aware that adaptive re-use of buildings is a continuing trend, due to high demand of residential accommodation in the city of Johannesburg. From their experience usage conversion increases the risks of fire outbreak in buildings within the city. In addition, various forms of fire safety non-compliance are observed during their inspections. Observations include poor management of designated fire exits. However the department faces major manpower and skills shortage, which affects its law enforcement capacity. As such effective commissioning, inspection and monitoring are hampered.

Facility managers interviewed on the other hand did not understand the fire safety implications or fire protection provisions of the buildings they managed. Furthermore they did not demonstrate understanding of fire safety regulations for the buildings and necessary compliance by occupants. They only recognised the provision of exit routes and fire fighting equipment following further elucidation during data collection. At this point, they also shared a common submission about the need for further compliance in their buildings. Moreover they did not conduct fire safety awareness and training for occupants.

On the part of occupants, there is virtually no awareness of the fire safety implications of the buildings they are occupying. While majority know that they occupy converted buildings, they do not know enough to relate to parameters of fire safety compliance which such buildings should adhere to. Other areas include lack of fire safety awareness and training. There were also no fire drills recorded. Majority complained of poor performance by facility managers and the fire department. Claims suggest that inspectors have not visited buildings under study since inception of the current occupancy.

Discussion

Generally there is evidence from respondents that fire outbreaks have occurred in converted buildings researched. Some of the outbreaks were reported as being major. Secondly there is lack of capacity with stakeholders researched. To substantiate the claim, findings show that the fire department is in need of skilled manpower. Facility managers also require adequate training in this regard. Occupants similarly need proper education with regard to fire safety and the peculiarity of the buildings they occupy. Thirdly while all parties agree to the use of pamphlets and leaflets for creating fire safety awareness, it was not implemented in any of the cases studied. Fourthly behavioural patterns of occupants were suggested as the main cause of fires. However occupants are dissatisfied with the degree of fire safety performance by building owners and the fire department. Furthermore there are disagreements between the parties with regards to the effectiveness of inspection and monitoring. Field observations confirmed the less than desirable fire protection status of the buildings researched. Problems seem to emanate from the conversion, usage and management of these buildings. Aspects such as stairways, corridors, signage, exit routes and escape outlets were called into question.

CONCLUSIONS

In conclusion, the paper is part of wider research agenda in building science, focused on fire safety. Data presented here is part of a degree project, on which limitations of time and scope were imposed. Data on identified causes of fires in buildings studied could not be obtained. Also access to all relevant parts of each building was not possible. However, main discoveries of the study so far point to a number of gaps in the execution, administration and regulation of building conversion, and its usage in Johannesburg city. In response to the guiding questions, findings suggest possible lapses in the following areas: design considerations for fire safety, the approval process, and lack of capacity in the monitoring system in place. Furthermore training and awareness, on the part of facility management and occupants are questionable. Deductions at this time lead to a number of propositions, which are stated below.

1. Building usage conversion increases the risk of fire in buildings within Johannesburg city. Also most buildings converted from commercial to residential use do not comply with fire safety regulations and the city by-laws
2. Most occupants in converted buildings within the city of Johannesburg are not familiar with building fire protection compliance needs. They are not fire safety aware and have not been trained with regard to fire emergency procedures. As such overcrowding, unit sharing by multiple families and poor housekeeping, are some key causes of fire in converted buildings within Johannesburg.
3. Stakeholders involved in converting buildings, cope with the challenges by avoiding certain areas which are not easily discovered during the approval process. Furthermore considerable amount of usage conversion occurs in Johannesburg without approval.
4. Johannesburg city fire department lacks the manpower in terms of volume and skills to adequately enforce the national regulatory demands and city by-laws, for fire safety and protection in converted buildings.

5. National regulations and additional city by-laws on building usage conversion do not address all peculiarities of building conversion; which could be linked to fire.
6. Most facility / building managers of converted buildings within the city of Johannesburg are not adequately trained, with regard to fire safety requirements, compliance and procedures.

Though not exhaustive, the above stated propositions present basis for subsequent research in the focus area.

Abstract:
Indigenous Australians in remote areas of the Northern Territory (NT) are subject to poor living conditions. This is a common problem and the development of sustainable social housing has become a significant challenge. Various procurement models used for project delivery have failed to address problematic issues that have led to poor health and reduced life expectancy amongst the indigenous population. Project delivery models for social housing are in need of reform to overcome the mounting problems and disadvantage in these indigenous communities. A current State and Federal Government initiative is the Strategic Indigenous Housing and Infrastructure Program (SIHIP). This program is using an Alliance procurement approach to deliver the planning, design and construction stages for social housing. Project Alliancing provides value for money, develops trusting relationships, appropriate management of team goals, multi-disciplinary expertise and innovative solutions for successful project delivery. Alliancing is characterised by project arrangements that ensure that risk is shared across all stakeholders under a pain/gain-share system to overcome adversarial and inefficient traditional contractual approaches. Using a case study approach, this paper analyses the SIHIP Project Alliance framework and focuses on principles for successful project delivery. The SIHIP has delivered sustainable housing projects for indigenous Australians and was particularly successful with regards to adaptability, effective program management and providing sustainable practices.

Keywords:
Australia, Indigenous Culture, Procurement, Project Alliancing, Social Housing.

1 Introduction

Effective management and use of resources throughout the entire construction process is the key to producing a successful product in the built environment (Harris et al, 2006). Project success is influenced by the procurement approach that provides a framework for all the aspects of construction to be holistically brought together (Walker, 2008). Therefore, procurement strategies can effectively drive the success, efficiency and sustainability of a construction project, and it is this that influences the aim of this paper within the context of identifying issues with the procurement of adequate and appropriate housing for remote indigenous communities. The provision of indigenous

social housing has been identified as a significant problem throughout Australian history. The likes of Memmot (1989), Pholeros (1993) and Read (2000), discuss the social, political and cultural problems with the construction and provision of houses in the remote Northern Territory (NT) of Australia.

Cheung at al (2005), Jefferies et al (2006), Walker and Hampson (2008) identify recent procurement innovations which have led to the development of contracting frameworks that aim to address the increasing nature of change and complexity of the construction industry. Formed around characteristics that develop relationships, share risk, drive collaboration and develop innovative solutions, Project Alliancing is a contracting system that embraces change, adapts to obstacles and enables participants to work together to achieve increased project performance and improve outcomes. It is the implementation of a Project Alliancing framework for the delivery of remote Australian indigenous housing (IH) in the Strategic Indigenous Housing and Infrastucture Program (SIHIP) that forms the basis of this paper.

Subsequently, the aim of this paper is to:

"Evaluate the SIHIP Project Alliancing procurement model in delivering cultural, economic and socially successful outcomes for Indigenous Housing."

The problems associated with indigenous housing are significant. Evidence is wide spread with overcrowded houses, poor performance of utilities, lack of maintenance and deteriorated, unsafe buildings (Pholeros 1993), (ABS 2006), (FaHCSIA, 2007), Indigenous Australians in the remote areas of NT have the lowest socio-economic profile of all Australians. The NT's Department of Local Government and Housing, in identifying problems with current IH, have proposed a solution which involves the use of different procurement models to provide adequate housing and services to remote indigenous communities. The development of the SIHIP led to the choice of Project Alliancing as the most effective contracting method for successful delivery of IH (FaHCSIA, 2009). Therefore, drawing on issues of remote IH and the successful attributes of Project Alliancing, this paper evaluates the success of the SIHIP in solving common problems with the provision of social housing in NT indigenous communities.

2 Indigenous Housing in Australia

The quality of housing and related infrastructure has always been a primary determinate of indigenous disadvantage, particularly in remote communities. The 1970s saw the first official identification of these issues and served as an element of concern for the living conditions, health and overall social wellbeing of the indigenous Australians. Rowley (1971) described housing as an issue decaying the standard of living of many remote aboriginal communities and the poverty, lack of education, violence and poor health was attributed to the primary issue of insufficient and inappropriate housing. Similar conclusions were drawn by Heppell (1979) along with the need for improved government policy aiming at the need to develop long-term strategic solutions to solve the problems with remote IH.

Both Memmott (1990) and Saunders (1990) provided an insight into housing policy for indigenous Australians and they covered the need for both state and federal policies to

understand the specific need for housing development. This related to holistic provision including design, construction and delivery of the projects that would be appropriate to the needs of remote Indigenous communities by paying specific attention to culture, living standards and sustainability. The situation in recent years has continued to be problematic with issues of overcrowding, low quality construction, poor planning, and lack of basic services and utilities (ABS 2002; Jefferies et al, 2011). Government reviews of IH programs also confirmed these problems, and not only with the housing itself, but also with the method of delivery. Specifically these reviews highlighted poor construction, lack of maintenance, inexperienced housing management, fragmented housing organisations and an inappropriate allocation of funding (FaHCSIA, 2007). Pholeros (1993), Read (2000) and COAG (2008) all identified the need for an improved system of procurement involving industry, government and community partnership in order to develop solutions to improve the day to day living environment. Reference has even been made to developing a specific section of the Building Code of Australia (BCA) for indigenous and remote housing and infrastructure (AIHW, 2005).

The current SIHIP is utilising almost A$700M of funding and is the largest IH program undertaken by the Federal Australian and NT State governments (FaHCSIA, 2009). The primary aims reflect those of similar policies and past programs, with additional objectives to improve remote indigenous built environments through the construction, rebuild and refurbishment of houses.

3 Project Alliancing

Construction projects are dynamic, ever changing and inherent with risks. Noble (2007) states that these levels of risk and the growing size and complexity of projects has attributed to the adversarial and fragmented nature of the construction industry. Project Alliancing aims at managing risks more effectively and encouraging collaborative and relational partnerships between stakeholders in order to better achieve project objectives and improve overall project performance. Walker (2008) also adds that Alliancing utilises the principles of risk sharing to better develop relationships and integrate the team to maximise project performance. According to the Victoria Government's 'Project Alliancing Practitioners Guide' (Dept. of Treasury and Finance, 2006), an Alliance is defined as "a commercial/legal framework between a department, agency or government-business enterprise as 'owner-participant' and one or more private sector parties as 'service provider(s)' or 'non-owner participant(s)' for delivering one or more capital works projects." Alliancing demonstrates characteristics of a partnership in that there is a collective sharing of almost all project risks and benefits, a no blame/no disputes agreement and an integrated project team personally selected who then use a principle based strategic management process. In partnership, each entity provides their services on a net cost basis and upon completion of the project the parties share in the profits and/or losses respectively.

Traditional forms of contract, such as Construct Only or Design and Construct, consist of project risks being allocated to the party believed best placed to manage the risk. The terms and conditions of traditional contracts aim at predicting all possible outcomes and assigning liability, so when changes or alterations occur, the result often ends in dispute. By comparison, Project Alliancing is built on a partnering ethos in order to embrace

collaboration, change and innovation in project delivery (Sakal 2005). Another prime characteristic of an Alliance is the early involvement of contractors and other stakeholders to encourage innovation, collaboration and allow the design, construction and occupation of the project to be integrated (Scheublin, 2001).

Alliance Contracting has been used on numerous Australian public sector capital works and infrastructure projects. To take advantage of this approach, some Australian State Governments have developed Alliance guidelines detailing the processes and framework for delivering major works. However, the use of Project Alliances to deliver building projects has been limited, the National Museum in Canberra a notable exception, and the SIHIP is one of the first major building projects to utilise this procurement system.

4 Research Methodology

Primarily, the data collected for this paper focused on published literature and secondary data. This allowed the researchers to understand the themes based entirely on the information at hand without opinion or subjectivity (Knight, 2008). The preliminary stages of research analysed current and historical literature to gain an understanding of the issue of remote indigenous housing and identified the need for a procurement approach specific to this problem. The principles of IH were established via a review of literature that identified both contributors and hurdles to successful outcomes. Subsequently developed into criteria, the principles were used to evaluate a case study of the Project Alliancing procurement system used for the SIHIP in the Northern Territory of Australia. The evaluation was based on the performance review documentation and published statistical data representing the outcomes of the SIHIP.

5 Results And Discussion: The Strategic Indigenous Housing and Infrastructure Program (SIHIP)

The Strategic Indigenous Housing and Infrastructure Program (SIHIP) is a current initiative of both the Australian Federal and NT State governments and is aimed at improving housing for indigenous Australians in remote areas of the NT. The program is the largest of its kind and SIHIP will construct new houses and refurbish existing houses in over 70 remote regions of the NT. Delivered using Alliance contracting, the SIHIP was developed to achieve the objectives of national IH policy and address the problematic issues of previous projects through timely and cost-efficient delivery.

5.1 Development of SIHIP

The SIHIP, as a part of the reform agenda outlined in the National Partnership Agreement on Remote Indigenous Housing (NPA RIH), was initiated in 2007 and formally announced in April 2008. The program replaced the previous arrangements of the Aboriginal Rental Housing and Community Housing and Infrastructure Programs following the trend of joint federal and state funding with state controlled delivery of this type of program. It was the agreement between the federal and NT governments which initiated the SIHIP in response to the recognition that previous housing programs had been unable to achieve desired outcomes (COAG, 2008). The project aimed to

address the large shortfall in housing stock, horrendous overcrowding, poor living conditions and overall community, social and economical disadvantage to the Indigenous population in remote NT (ABS, 2006).

Previous programs were failing to achieve the desired stakeholder outcomes and this prompted a change in program structure and project delivery. The general delivery method was previously standard one-off, lump-sum contract agreements, and these programs continuously failed to achieve value-for-money or the economies of scale needed for successful outcomes, particularly in unique projects such as this. Presented with a range of business and policy challenges unique to the remote Indigenous regions of the NT, such as cultural and social considerations, history, heritage, environmental and climate restrictions and limited resources, the government agreed that an alternative procurement approach may be able to achieve the required outcomes (FaHCSIA, 2009). A procurement system which provided an incentive for quality, sharing of risk, responsibility and benefits, and greater elements of indigenous employment, training and overall community development would be a significant driver for change to achieve more sustainable improvement.

The aim of the SIHIP was to deliver new housing, refurbish and upgrade existing housing, improve living conditions and provide new infrastructure and capital works. The program was initially provided with $538 million worth of funding from the Australian Government and an additional $100 million from the State Government. The NT Government delivered the program through the Project Alliancing procurement system and was also responsible for property management, rent collection and routine maintenance though its public housing framework. The Australian government would provide support throughout the program, oversee the delivery and provide governance and guidance of key decisions and the strategic direction of the program.

5.2 The Project Alliance Approach for SIHIP

Through best practice procurement, a Strategic Alliance system was adopted in order to achieve the program objectives. It was determined that Alliancing had the potential to achieve greater economies of scale, better value for money, and grab the attention of innovative and successful companies who had the ability to partner with smaller local firms capable of integrating and engaging the local community (FaHCSIA, 2009). Initiated in 2007, the SIHIP was based around the principles outlined in the Victorian Governments (2006) 'Project Alliancing Practitioners Guide' and more specifically characterised by the following:

- Collective sharing of project risks;
- No fault/No blame/No dispute between Alliance participants;
- Payment of non-owner participants (NOPs) for their services under a '3-limb' compensation model:
    - *Reimbursement of NOPs project costs on a 100 percent open book basis;*
    - *A fee to cover corporate overheads and normal profit; and*
    - *A gainshare/painshare regime where the rewards for good performance and the penalties for poor performance are shared equitably.*
- Unanimous principle based decision making on all key project issues;
- Integrated project team selection based on best person for each position; and

- Early involvement of contractors.

Specific details of the SIHIP Project Alliance are summarised in Table 1.

Table 1: The Structure of the SIHIP Project Alliance

PROCUREMENT SYSTEM	Alliance Contract System: Separated into 3 regional project alliance partners assigned work packages in separate geographical regions. Engaged to collaboratively manage the delivery, design, construction, refurbishment and management/maintenance of the project
GOVERNANCE	*NT State Government:* Contracting entity, responsible for the delivery of the program, management of contracts, organisation of land tenure, capital works and development planning. *Australian Federal Government:* Strategic guidance and management of the program and contracts; development and support during procurement process and program establishment.
ALLIANCE STUCTURE	Governed by the agreement between the federal and NT governments the alliances consist of a combination of the following: • Head Contractor; Developer; Local Construction Firm; Engineering firm; Civil Contractor; Specialist Trade Contractor; Building services company; and Suppliers
ALLIANCE DELIVERABLES	The alliance method led the Australian and NT Governments to select and engage professional services including: • Program management services; Cost management; Design coordination; Construction management; Financial Audit services; Value for money
TIME FRAME	Completed by the end of 2013
DELIVERABLES	New Houses = 750; Rebuilt Houses = 250; and Refurbished Houses = 2500
METHOD	Phase 1- *Selection of alliance partners* Phase 2- *Planning and Development* Phase 3 - *Delivery/Construction*
PARTNERS	*Earth Connect Alliance:* • Canstruct Pty Ltd; WorleyParsons Pty Ltd; Force 10 International Pty Ltd; Greene & Associates Pty Ltd; and Ostwald Bros. Pty Ltd *New Future Alliance*: • Leighton Pty Ltd; Broad Construction Services Pty Ltd; Opus Pty Ltd; and Ngarda Civil & Mining Pty Ltd *Territory Alliance Partners*: • Sitzler Pty Ltd; Laing O'Rourke Australia Construction Pty Ltd; McMahon Services Australia Pty Ltd With a Sub Alliance Participant: • Compass Group (Australia) Pty Ltd
INITIAL BUDGET	Australian Government: $ 547 Million NT Government: $ 100 Million Additional: $ 25 Million Total = $672 Million
ESTIMATED UNIT COST (from cost planning process)	New House Target Cost: $350,000 Estimated Regional Package Cost: $30-$50 million

5.3 Principles for Success

The procurement system must successfully address the issues present through the delivery of a housing project that achieve sustainable housing and associated outcomes (Tipple and Willis, 1991). Identifying the primary issues associated with remote IH is the first step in developing the project objectives and subsequent desired outcomes for the SIHIP. Through thematic and statistical analysis of literature, government surveys

and statistical reports, a number of themes were established as key principles for success in the procurement of IH. These principles affect the success of remote housing programs and are critical issues that can assist in improving the outcomes of remote IH in the NT. These 11 principles are listed below, however, due to the word limit constraints of this paper, only the first two (2) are reported in detail here. The other nine (9) principles are discussed elsewhere (see Jefferies et al 2011; Jefferies et al, 2012). The 11 principles for success in the SIHIP Project Alliance are:

1. Sustainable Practices; 2. Effective Program Management; 3. Adaptability; 4. Community Involvement and Consultation; 5. Regional Focus; 6. Value for Money; 7. Cultural and Social considerations; 8. Design Suitability; 9. Economic Development; 10. Construction Standards; and 11. Time.

The following discussion of 2 of the key principles for success draws upon the outcomes of 'The Review' (FaHCSIA, 2009) and the 'Post Review Assessment' (PRA), (Donald and Canty-Waldron, 2010).

5.3.1 Sustainable Practices

For the SIHIP to successfully achieve its objectives the outcomes must be sustainable. In turn the Program must foster growth and future development to ensure that the work completed benefits the current population while improving outcomes for future generations (Walker et al, 2003). The Project Alliance framework has enabled engagement of local suppliers and firms to assist in the delivery of the SIHIP. Through economic development this stimulates economies for sustainable employment and stabilises local economies. The engagement of local suppliers and producers can contribute to environmental sustainably if arrangements such as that of the similar Hopevale project are in place, where the housing designs were based on a locally grown and manufactured bamboo floor and wall panelling product (FaHCSIA, 2007). Even so, the use of local suppliers still assists the sustainability of these suppliers as costs and transport emissions are reduced by smaller distances for importing materials/resources.

The PRA concludes that the collaboration between government and alliance partners is directly attributed to the program achieving sustainable outcomes as well as broader social and economic benefits (Donald and Canty-Waldron, 2010). In addition the integration of maintenance and asset management practices into the delivery process can affect the long-term sustainability of the project outcomes. Through incorporating maintenance schedules and asset management principles in the early stages of the project, management of the dwellings during occupation can be improved. The involvement of local resources also contributes to this factor, as the training of local workers enables an understanding of buildings and their associated maintenance needs, to ensure that the buildings are not only maintained to the standards that they were built, but the occupant and users will hold them in higher value due to their involvement in the construction, design and maintenance processes.

The PRA states that the "failure of past procurement models in delivering sustainable outcomes in remote areas indicates that Alliancing and other non-traditional procurement methods are far more suited to implementing sustainable practices and achieving outcomes" (Donald and Canty-Waldron, 2010). Issues that arose with the

management structure of the program led to unbalanced elements of consultation, quality, time and cost. This lead to the initial packages of work to be declared unsustainable, and would not achieve the objectives across the entire project (FaHCSIA, 2009). Although some aspects of the management and implementation processes of the Alliance model require revision, this is due primarily to the fact that this is a somewhat untested procurement method for the delivery of IH. Overall the SIHIP alliance framework utilises sustainable practices to a moderate level.

5.3.2 Effective Program Management

A key function in the management and governance of the SIHIP was the development of relationships, collaboration and the integration of the program. The nature of the Alliance framework enabled a strong relationship to develop between all stakeholders from a very early stage with collaboration then encouraged and the integration of many of the Program's functions. Evidence of this lies in the Post Review Assessment where the efforts of the Program Managers to utilise the potential of the Alliance system. In particular, developing an 'open-book' approach by providing the Alliance partners with policy agreements on objectives, targeted costs and outcomes developed by the State and Federal Governments which removed the ambiguity of costs and scope of works for the project. This enables increased overall performance in the delivery of the housing outputs (Donald and Canty-Waldron, 2010).

During the review it was found that program management and administration costs were too great, running at 11.4% of the total budget for the program. This was understood to be resulting from inefficient management structure, a high level of external contractors in regular government management positions and an over complex Post-Development Report (PDR) process. With the SIHIP being a pioneering use of the Project alliance system in the NT, and indeed for large scale housing programs, these issues can be contributed to the inexperience of all participants including the NT and Australian governments. As the development of the management structure and processes were based on very little precedents, and the initial stages of the alliance development was resource intensive, in turn this became cost intensive.

Following the review, the governance structure was streamlined and revisions were made to the PDR process, and several outsourced (contractor) positions in government were subsequently filled with government employees. This had the effect of reducing the Program management and administration costs to under 8% (Donald and Canty-Waldron 2010). The review also identified that despite the immediate achievement in program costs and management organisation, more focused, and greater resourcing would be needed, particularly in communities to effectively support the overseeing and management of the project works. Overall the effect of the Alliancing system on program management is positive, although the inexperience of both government and NOPs, and for efficient management of a program of this scale some revision is needed as it can often only be discovered through trial and error. At this stage, the level of which the Alliance model addresses the efficiency of program management is somewhat minor but with promising improvements.

6 Conclusions

Housing conditions for indigenous Australians in remote parts of the Northern Territory are well below the standards of the rest of the country's population. Overcrowding, poor living conditions and even homelessness have not been solved by previous programs. Delivery methods for remote Indigenous housing are in need of reform to address the problems and disadvantage of these communities. Successful housing outcomes are driven by the holistic procurement of design, construction, management and maintenance services. Using a case study analysis of the SIHIP Project Alliance, 11 principle success factors were identified as being critical for this project. This paper identified these 11 principles, but due to word limit constraints of the paper, only 2 of them are reported in detail. The 2 reported principles being 'sustainable practices' and 'effective program management'.

The SIHIP is the largest scale program of its kind in Australia and is improving the outcomes of remote Indigenous housing. Project Alliancing is providing a shift from traditional contracting methods and subsequently offering a range of benefits to improve IH. The SIHIP Alliance framework was found to encourage collaboration, embrace innovation and allowed all participants to work as an integrated team towards reaching the project objectives. Repeatedly defined as being suited to complex and dynamic projects that have an undefined scope of works, Alliancing is as an appropriate procurement method to be applied to the ever-changing problem of remote IH delivery. Project Alliancing is a pioneering procurement method and the SIHIP is the first time this approach has been applied to a Capital Works program in Australia's NT. Through greater experience and further commitment with relational contracting methods, Alliancing will be at the forefront of project delivery of IH programs for remote Australians and ultimately should help to close the disadvantage gap.

The findings reported in this paper warrant further research into the procurement of remote IH. SIHIP has shown that Project Alliancing has the potential to improve the outcomes of similar challenging projects and has the ability to change the way in which other large-scale Public Sector projects are procured. The following areas are recommended for further research in order to improve IH procurement:

- Conduct further analysis of SIHIP outcomes on project completion in 2013;
- Assess the impact of policy and legislation on procurement methods for IH; and
- Develop relational contract conditions for standard Australian construction contracts such as AS2124 and GC21.

Abstract:
The prevailing tendency within English law is to regulate the home differently according to whether the occupier is a renter or owner. However, by taking tenure classification as a starting point current regulation focuses too heavily on form. A functional, substance-based approach should be adopted, that begins from the common feature that the property is a home. Differences in regulation are acceptable provided that they are objectively justified rather than being based simply on tenure classification. The terms 'owner' and 'renter' imply homogeneity within each of these tenures but they are misleading and obscure significant differences. Consistent policies have helped to make owner-occupation the normal tenure, at the expense of the rental sectors, yet the home as a distinct entity is largely unrecognised by the law governing owner-occupiers. The legal structure of Low Cost Home Ownership schemes helps to reveal the fundamental weaknesses of using tenure categorisations as a starting point for regulation.

Keywords:
Home, owner, regulation, renter, tenure.

1 Introduction

The prevailing tendency within English law is to regulate the home differently according to whether the occupier is a renter or owner. The primary purpose of this paper is to show the inadequacy of tenure classification as the basis of legal regulation. Our thesis is that by taking tenure classification as a starting point current regulation focuses too heavily on form. We argue that a functional, substance-based approach should be taken, that begins from the common feature that the property is a home, irrespective of the tenure under which it is occupied. We do not suggest that all homes should necessarily be regulated in the same way, but that differences must be objectively justified, rather than being based simply on tenure classification. This rebalancing is of central importance since tenure classification determines occupiers' legal rights and can lead to significantly different consequences depending on the way in which the person's occupation is classified. Our starting point is two-fold: first, Lorna Fox's ground-breaking work which demonstrated the existence of a particular concept of home (Fox 2007); and secondly Britain's obligations under the European

Convention on Human Rights which have brought an increasingly consistent jurisprudence from the European Court of Human Rights that adopts an autonomous meaning of home under Article 8 that is not restricted to traditionally defined legal rights.[2]

Criticism of tenure analysis is not new, but our contribution is to examine tenure through the lens of property law. By using this approach to deconstruct the categories of owner and renter, we highlight the lack of homogeneity within tenures both in terms of the legal rights of each as well as the characteristics of those who live there. We demonstrate that the differences between owning and renting are not inherent, as is sometimes suggested, but reflect policy choices. We identify a consistency in policy that has seen the acceptance of owner-occupation as the normal tenure and the association of ownership with specific benefits that need not, in fact, be confined to this category. The emphasis on owner-occupation is important because it has come at the expense of renting. Successive government policies have reduced the rights of renters, whether in the private or social sectors, and so reinforced the desirability of owner-occupation. These choices provide the foundation of an ideology of home ownership in which the status of homeowner becomes a social ideal (Ronald 2008: 2).

Our analysis is timely as the ideology of home ownership is starting to be questioned. Owner-occupation in its traditional form is increasingly unavailable to large sections of the British population – initially as a result of rising house prices (which remain unaffordable to many despite more recent falls) but now additionally through more conservative lending practices following the global financial crisis. Consequently, more imaginative housing solutions have been sought, particularly through Low Cost Home Ownership (LCHO) schemes that have been used to fill the affordability gap between government ambition and the personal desire for home ownership on the one hand and the ability of purchasers to buy a home using commercially available finance on the other. A commonly used legal model for the delivery of LCHO is shared ownership, known as part-buy, part-rent. As its name suggests, it leaves purchasers with a foot in each of the tenures, a situation reflected in the legal rights and responsibilities of purchasers (Bright and Hopkins 2011). As such, the traditional divides affecting the regulation of homes is being increasingly blurred. There is also a growing awareness of the risks of home ownership and of the undesirability of having one's financial security tied-up in a single asset (Fennell 2008, Smith, Searle & Cooke 2009, Heywood 2011). As a consequence of both these factors, the trajectory is no longer one way and there are early signs of a move to a post home-ownership era. As the focus shifts away from traditional home ownership, the function of the property as a home will become even more significant.

2 Tenure Trends

To provide background to our discussion of tenures, we first consider tenure trends within Britain. The purpose is not to attempt a full description, which is well documented, but to highlight the role that policy choices have played in the tenure trajectory and to place that trajectory in a comparative context. During the course of the 20th century, Britain changed from a nation of private renters to 'a nation of home-

[2] *Gillow v UK* (1986) 11 EHRR 335; *Buckley v UK* (1996) 23 EHRR 101.

owners' (Saunders 1990). The 20th century also saw the development of the public rented sector which at its peak housed a third of the population. Since then, because of homes lost through the Right to Buy (RTB) and lack of reinvestment, the public rental sector has become increasingly residualised (a characteristic it has arguably always had) (King 2010).

Owner-occupation in Britain was on an upwards trajectory from the early part of the 20th century and reached a peak of 70% at the turn of the 21st century. Since then, the global financial crisis has seen an unprecedented dip and the trajectory has been downwards since 2007. It now stands at around 68% (Department for Communities and Local Government, Live Statistical Tables). This level of home ownership is not unusual in developed countries and similar rates are found in the USA and Australia (US Census Bureau 2011, Australian Bureau of Statistics). A more diverse pattern emerges throughout Europe. In Germany, home ownership has remained below 45%. Voigtlander attributes this to a number of factors, including strengths in the private and social rented markets and the existence of a genuine choice (Voigtlander 2009). In contrast, in some Eastern European countries the sale of State-owned housing following the collapse of socialism has seen home ownership rise above 90% (European Mortgage Federation 2011).

Thus at the present time, and since the early-to-mid 1980s, owner-occupation is seen as the 'normal' tenure. The privately rented sector (PRS), a tenure for all at the start of the 20th century, is now seen principally as a sector for short term occupation for the young and upwardly mobile (Rugg and Rhodes 2008). The classic view of the PRS tenant is someone who is not yet ready to enter owner-occupation. The social sector, comprising public sector landlords and Registered Providers (bodies with a hybrid public-private status), acts principally as a safety net for the poor and vulnerable. Until a recent policy development, discussed below, it has offered a permanent housing solution for those who will probably never be in a position to be owner-occupiers. Those who can move out of the sector into home ownership have been encouraged to do so through discounts and grants.

The trajectory of tenure has not been exclusively driven by policy choices. There has never been any 'grand plan' in terms of the ideal composition of the housing market and it is undoubtedly the case that changes have occurred as a result of factors that were unplanned or unintended. Notwithstanding, it is equally apparent that policy choices have been made which have intentionally impacted on tenure. Housing tenure became politicised from the 1950s. This was after the first significant expansion of home ownership had taken place, but before a second expansion that was led by the Conservative administrations of the 1950s and early 1960s. By the end of the 1970s it was apparent that owner-occupation had reached saturation level in terms of the ability of people to move from the PRS to owner-occupation through their own resources. Any further expansion would therefore come at the expense of the public rented sector. This was embraced by the Conservative government's manifesto (under Prime Minister Margaret Thatcher) commitment to the RTB. Despite the Labour Opposition's hostility to this policy, it was maintained by Labour when in government between 1997 and 2010, and the current British Conservative-Liberal Democrat coalition government has recently reinvigorated it by increasing the maximum discount that can be accrued. Equally, the short term nature of the PRS

tenancy has been maintained under governments of both political complexions. As such, owner-occupation as the normal tenure has now become accepted by all the major political parties.

3 Property Relationships And Policy Choices

Against the background of tenure trends, we turn to consider the heterogeneity that exists within each tenure which reinforces our contention that tenure classification is an inappropriate starting point for regulation. We also show that the differences between the tenures are not inherent but reflect policy choices. What we find is a re-enforcement between the promotion of home ownership as the tenure of choice and the construction of the tenures so that specific benefits come to be seen as associated with home ownership.

3.1 What is an owner?

Home ownership is generally associated with a range of financial and non-financial benefits. The extent to which they can be enjoyed only by homeowners has proved contentious and Saunders' (Saunders 1990) claim that owners experience the home differently has been significantly doubted, including Fox's work (Fox 2007). Nevertheless, the *Public Attitudes to Housing in England* report (Wallace 2010) shows that the large majority of people in England would choose to buy rather than rent. The advantages of owning rather than renting are identified as being that: (a) it is a good investment; (b) it is more secure in the long-term; and (c) it gives the occupier freedom to do what they want with the property.

The heterogeneous nature of the tenure, and the ability to access these benefits, can be illustrated by three examples. First, the problematic position of long leaseholders as owners has been established by Cole and Robinson's work which aptly summarises their position through the description "owners yet tenants" (Cole and Robinson 2000). Secondly, the category draws no distinction between those who own their home outright and those purchasing through mortgage finance. But for the purchaser the benefits of ownership are dependent on the continuing ability to pay the mortgage. The purchaser also has an enduring relationship with the mortgagee, which by section 87 of the Law of Property Act 1925 is placed on the same footing as that between a long leaseholder and their landlord. Thirdly, Bright and Hopkins have highlighted the different nature of home ownership arising under English LCHO schemes, where both the financial and non-financial benefits obtained may fall short of those associated with 'traditional' home ownership (Bright and Hopkins 2011 and 2012).

3.2 What is a renter?

In Britain, the term renter encompasses those who rent from a private sector landlord, a public authority landlord and a Registered Provider landlord. The tripartite distinction between these three categories is reflected in official statistics. However, even within these sub-categories not all renters have the same legal rights in relation to their home. The category of renter includes both those with property rights (a lease) and those with personal or contractual rights to occupy. Renters do share a number of common features: (a) the legal interest through which they occupy their home is carved out of a superior, freehold interest; (b) they all have a direct

relationship with a landlord; (c) they each pay a regular rent that represents the entirety of the cost for the home, so distinguishing them from long leaseholders. Hence, renters have no "investment" interest in their home; they pay to 'use' the property while the investment interest remains with the landlord; and (d) they each derive their security of tenure and other rights partly from contract and partly from a statutory scheme.

Despite these common features there are significant points of disparity. Each is governed by a separate statutory scheme and there is a huge variation in security of tenure (and other rights) within those schemes. Some tenants are able to buy the property in which they are living through the RTB (or for tenants of Registered Providers, the Right to Acquire). The status of the landlord is different. This feature is particularly significant when human rights issues are at stake since only public authorities and sometimes Registered Providers[3] are subject to the Act.[4] There is also huge variation in the characteristics of those who rent – from students and young, mobile professionals, to families with children, the homeless and asylum seekers. Even within rental sub-sectors, there is great heterogeneity (Rugg and Rhodes 2008).

3.3 Heterogeneity vs homogeneity within the traditional tenure classifications

The heterogeneity within tenures arises because the categories of owner and renter are political constructs, not legal ones. As we explain further below, consistent government policy has sought to emphasise clear lines of demarcation between owning and renting. This dichotomy is reflected in the starting point for regulation of each. Owners come within the auspices of property law, while renters are regarded as being within the purview of housing law. This is not merely a semantic difference but reflects fundamental distinctions concerning the way in which the home is perceived. For housing law, the concept of home is uncontroversial; a primary requirement of the current statutory schemes that regulate the residential landlord-tenant relationship is for the occupier to occupy the dwelling-house as their "only or principal home".[5] By contrast, in property law housing tenures cannot be directly defined by the legal relationship between people and their homes. Here, the focus is the relationship between a person and the "land" on which the home is a fixture or constituent part. What is owned is an "estate" over the land; a bundle of rights enjoyed either forever (as a freehold) or for a lesser period of time as a lease. Importantly, there is no inherent difference in the rights of ownership that can be enjoyed over a freehold or leasehold estate; the difference relates only to the duration for which ownership will be enjoyed. As such, the heterogeneity within the tenures has been obscured by the divisions between owning and renting that have developed from these different starting points.

3.4 Policy and tenure

Housing literature reveals differences of opinion as to whether there are specific characteristics inherent within each of the tenures. Ruonavaara distinguishes between "essentialist" and "constructivist" approaches to tenure classifications (Ruonavaara 1993). The essentialist approach treats housing tenures as "fixed entities with certain

[3] *R (Weaver) v London and Quadrant Housing Trust* [2009] EWCA Civ 235, [2010] 1 WLR 363.
[4] Human Rights Act 1998, s 6.
[5] Housing Act 1985, s 81; Housing Act 1988, s 1(1)(b).

advantages and disadvantages from the point of view of the consumer" (Ruonavaara 1993: 6). This contrasts with the constructivist view that "housing tenures have no natural properties but rather their properties are historically and socially constructed" (Ruonavaara 1993: 6). Ruonavaara argues in favour of an approach that he terms "moderate constructivism". This approach distinguishes between "necessary properties" of housing tenures that are "associated with a certain type of tenure ... by definition" and "contingent properties" that can vary within the limits of the necessary properties (Ruonavaara 1993: 11). Our contention is that an attempt to identify such characteristics is misplaced. From a legal analysis there are some inherent differences between a freehold and a lease, but these are confined to the existence of a relationship of landlord and tenant, not its content. The rights associated with owners and renters are not inherent but are policy choices layered on top of the inherent legal characteristics.

There are a number of examples that could be used to illustrate this point, but for the sake of brevity we refer to just one, the right of disposal. Saunders argued that the right of disposal is essential to ownership and, in his terms, "can never be extended to tenants, simply because the house is not theirs to give" (Saunders 1990: 100). As a matter of law, however, there is no inherent reason why the holder of any property right should not be able to dispose of that right. Hence, for example, there is nothing inherent in the legal estate (the lease) given to a public sector tenant that explains the absence of a right of disposal. The absence of such a right is of course readily explicable, but as a policy choice of ensuring that publicly provided housing is distributed in accordance with an allocations policy. Saunders notes the limited rights of succession that have been conferred on public sector tenants, which he dismisses as falling "a long way short" of a general right of disposal (Saunders 1990: 100). But the existence of such rights represents a further policy layer, that the absence of rights of disposal should, in some circumstances, give way to other objectives. Conversely, not all owners enjoy the same rights of disposal. In particular, disposal has sometimes been limited or restricted in LCHO schemes. This has been done, again, through a policy choice that the individuals' right to dispose should give way to other objectives, such as keeping the unit within the LCHO sector and providing mixed, sustainable communities (Bright and Hopkins 2012).

Equally, there is no reason why the principal advantages of owning identified in the *Public Attitudes to Housing in England* report (Wallace 2010) – investment, long-term security and freedom to do what you want with the property – should be enjoyed by owners and denied to renters. For example, we can see by reference to the way in which the PRS was regulated until 1988 (under the Rent Acts) that it is possible to give tenants significant security of tenure and the ability to pass the property to future generations through the rules on succession; both features that are more commonly associated with owner-occupiers. The relative lack of security of tenure that tenants in the PRS today experience is the direct result of the Housing Act 1988 which sought to deregulate the PRS. Equally, the RTB demonstrates that it is possible for a tenant to invest in their property. The scheme gives public sector tenants the right to buy their existing home at a discount that is based on the number of years that the tenant has been paying rent to the public authority landlord. Thus, while it may not have been the tenant's intention from the outset of the tenancy to buy their rented home, nevertheless, the rent paid effectively acts as an investment in a later purchase.

Conversely, the investment, security and freedom associated with traditional owner-occupation are all limited in LCHO schemes (Bright and Hopkins 2012). The point of importance is that all these features represent policy choices.

We have demonstrated that owner-occupation has come to be seen as the normal tenure, yet in this sector 'home' is a political rather than a legal construct. As Fox has shown (Fox 2007), even where the law acknowledges the home value of the property, there is a strongly pro-creditor bias in disputes involving home owners and lenders. By contrast, the regulation of the rental sectors acknowledges the home as a distinct entity but recent policies have moved in the direction of removing renters' security of tenure, thereby increasingly making owner-occupation the only way of securing long-term housing. However, without a fundamental rethink of the starting point for legal regulation, the significance of the property as a home will remain obscured. The change to a functional-based approach is even more important in light of the development of LCHO schemes which, as we have explained, combine features of both owning and renting.

3.5 An emerging distinction: the 'social' and the 'market'

Having established the inadequacy of tenures, in the final part of the paper we consider a different distinction – that between social and private (or market) based housing. This distinction is commonly drawn in relation to the rented sector. It is less frequently discussed in relation to ownership, but it is undoubtedly present and is becoming more visible having received statutory recognition and definition.[6] As a result, we see the emergence of a distinction between social and market housing that crosses the tenure divide.

The question of what is "social" about social housing is a contentious one (Cowan and McDermont 2006), but there are significant features shared by social housing, whether rented or owned. First, social housing is a site for social policy. The involvement of the state enables housing to be used for objectives other than the provision of a roof over the head. In the rented sector, in particular, this has negative connotations and social housing is seen as a site for social control (Cowan and McDermont 2006). In the owner-occupation sector the connotations may be more positive and state involvement has been used, for example, to build mixed sustainable communities. Secondly, access is governed by eligibility criteria principally according to need, although the nature of the need may be defined differently as between renting and owning. Thirdly, costs are below market level. Hence, rent in social rented housing is below market level. Equally, the rent payable by a shared owner for the "part rented" is set at an "affordable" level.

Thus, for regulatory purposes, the distinction between market and social housing (whether owned or rented) may now be a more relevant one than that between owners and renters. In particular, the broader social policy objectives that social housing seeks to achieve provide an objective point of departure from market housing that may legitimately be reflected in the regulatory regime. As Elias LJ commented in *R (Weaver) v London and Quadrant Housing Trust* "[t]he provision of social housing as opposed to the provision of housing itself is in my opinion a function which can

[6] Housing and Regeneration Act 2008, s 68.

properly be described as governmental. Almost by definition it is the antithesis of a private commercial activity."[7]

Nevertheless, we do not suggest that this distinction, any more than tenure classification, should provide a starting point for regulation. The existence of a clear dichotomy between social and market housing would be disputed. Furthermore, whereas both market and social owners and social renters currently all enjoy significant security of tenure (subject to certain qualifications), as we have seen market tenants have only limited rights. This disparity is the result of policy choices that reflect successive governments' views that the appropriate role for the PRS is as an essentially transitory form of housing. In any event, any distinction is blurred; for example, LCHO schemes that cross the divide between owner and renter also combine features of social and market housing. Equally, recent developments in the social rented sector may be seen to blur the divide between market and social rented housing. A new form of social tenancy – the flexible tenancy – has been created.[8] Whereas social tenancies have traditionally been viewed as offering a home for life, the flexible tenancy is for a fixed period. This feature allows public sector landlords periodically to review the tenant's continuing need for housing and, as such, reinforces the social policy objective that this form of housing is reserved for those in greatest need (Department for Communities and Local Government 2010). Yet it can also be seen to reduce the distinction between market and social rented housing, a key feature of which is the stark difference in security of tenure. Viewed in this light, it may be argued that the policy encourages would-be social tenants to regard the PRS as an acceptable alternative.

In summary, while the market / social division is superficially attractive, it remains highly problematic. We see the lack of a dichotomy, or the blurring of the distinction, as reinforcing our broader thesis that the functional use of a property as a home should provide the starting point for regulation. Nevertheless, the market / social distinction may be a useful tool in informing principles of regulation.

4 CONCLUSIONS

We have shown that tenure is inadequate to provide the basis of legal regulation of the home. The predominance of owner-occupation in Britain is not unique, nor was it inevitable. Its causes are multiple and complex, but policy choices have been made which have seen owner-occupation develop first at the expense of the PRS and then at the expense of the social rented sector. We have also seen that the content of the tenures has been constructed to reinforce the policy of promoting home ownership. These choices provide the foundation of an ideology of home ownership in which being an owner comes to be seen not merely as a means to an end but as an end itself. Yet the home value for owners remains obscured because of the starting point of its regulation. By contrast, the rental sectors recognise the concept of the home but policy developments have reduced renters' security of tenure; first in the PRS and more recently in the social sector. Schemes to fill the affordability gap in owner-occupation combine features of owning and renting, further blurring the traditional

[7] *Weaver* (n3) [70].
[8] Localism Act 2011, s 154.

categories. Collectively, these developments strengthen our argument that it is necessary to rethink the starting point for regulation, based on the common feature that the property is a home.

AN ASSESSMENT OF THE IMPACT OF FOREIGN DIRECT INVESTMENT (FDI) ON CONSTRUCTION SECTOR OUTPUT (CNS) AND GROSS DOMESTIC PRODUCT (GDP) IN EASTERN AFRICA

Saka Najimu[1] and Lowe John[2]

[1&2]*School of Engineering and Built Environment, Glasgow Caledonian University, Glasgow, Scotland, United kingdom G4 0BA,*

ABSTRACT

Following the debt crises of the early 1980s, the economic paradigm of most developing countries took a complete turnaround with the adoption of outward looking economic policy. Thus foreign trade and investment became integral part of the new economic development strategy. The study investigates the impact of the Foreign Direct Investment (FDI) on Construction Sector Output (CNS) and Gross Domestic Product (GDP) in five Eastern African countries. The study is based on a 40 year annualized time series data (1970-2009) extracted from the United Nations Conference on Trade and Development Statistics (UNCTADStat). The study employs econometric methodology specifically the Vector Error Correction Model (VECM) and Panel Regression Model. The result indicates that FDI significantly impacted on both the CNS and GDP. The study recommends improving investment climate to facilitate increase FDI inflow to support sustained growth of the construction sector and GDP in the region.

INTRODUCTION

Many decades of economic stagnation have turned Africa into the world's poorest region (Sachs et al 2004 & Collier 2006). With a gross national income of less than USD765 per person per year, the average African lives on less than USD1 a day in 2008. This is exacerbated by disease, famine and conflicts (Asiedu 2004, IST-Africa 2009). The continent is faced with depreciating local currencies, declining investment, trade, remittances and rising interest rates, input costs and unemployment. This means reduced income for development and risking a further increase in the number of people living under the poverty line (UNDP, 2009). One of the critical causes of Africa's economic woes is inadequate infrastructure (World Bank, 1994). Africa

1 saka.najimu@gcu.ac.uk
2 j.lowe@gcu.ac.uk

ranks consistently at the bottom of all developing regions in terms of infrastructure investment (Calderón and Servén 2008). The poor state of infrastructure in Africa cuts national economic growth by two percentage points every year and reduces productivity by as much as 40 percent (Foster and Briceño-Garmendia 2010). Africa must therefore massively develop its infrastructure to fast track its economy, reduce poverty and catch up with rest of the world (World Bank 2006 & Calderón and Servén 2008).

To close the infrastructure gap with the rest of the world, hundreds of billions of dollars will be required (Briceño-Garmendia Smits and Foster 2008). Considering the wide savings-investment gap in Africa, financing the massive infrastructure deficit will require International Capital Flows (ICF) (Foster and Briceño-Garmendia 2010). ICF helps developing countries to bridge savings-investment gap, eliminate foreign exchange shortages, deepens local financial markets, cushion shocks and promote sustained growth / development and integration into the global economy (UN, 2001 2007, Ernst & Young, 2011). Given the deleterious effect of ICF like debt/Loans in the past, only Foreign Direct Investment (FDI) flows can truly benefit African infrastructure development (Ngowi, 2001). FDI has become one of the most potent sources of capital formation across the globe. The experience of the Asian countries (for example China) indicates that FDI is critical to achieving the growth rates Africa needs to build modern physical infrastructure (ADB 2004 & UNCTAD 2001). Hence greater importance is now being placed on FDI by African countries (ECOSOC, 2000). With the rapid expansion of FDI in the global economy, the effect of FDI on the host economy, particularly the construction sector has lately been contentious. Empirical studies on the effect of FDI on developing economies have generated mixed results (Adams 2009). The mixed findings reached by studies on the role of FDI on growth suggest further investigation.

LITERATURE REVIEW

Until the mid-1980s, most developing countries viewed FDI as a modern form of economic colonialism and exploitation. Consequently, most developing countries regulated and restricted FDI flow (McCulloch 1991). However, the debt crises of the 1980s, pressure from International Financial Institutions (IFIs) and evidence from developing countries that have embraced FDI forced many developing countries to reform their economies policies to attract FDI (ADB, 2004). Some FDI policies pursued by African countries include investment treaties and promotion, trade and exchange rate liberalization, privatization and tax holidays etc (APF 2007 UN 2007 UNCTAD 2007). These efforts appear to be yielding positive result as investors from emerging economies – China, India, Malaysia and South Korea – are now positive about Africa's attractiveness. FDI into the continent is forecast to reach USD150 billion by 2015 from USD84 billion in 2010, driven by strong growth in new projects (APF 2007 & Ernst & Young 2011).

The construction sector is by far the single largest contributor to infrastructure or Domestic Fixed Capital (DFC) in developing countries. Over 50percent of DFC is related to the output of the construction sector (Hillebrandt 2000). Thus adequate constructed infrastructure facilities will solve Africa infrastructure challenges by more than 50percent. However, the Eastern Africa Construction Sector (EACS) is largely underdeveloped and beset by a number of challenges reflecting largely the level of development of the region (Msita 1998 Rwelamila 1996 Lema and Price 1998 Kivaa

1999 and Ministry of Works 2003). Additionally, factors include heavy dependence on government expenditure, competition from Chinese construction companies and the high cost of borrowing (Frost & Sullivan 2010). The challenges facing EACS strongly suggest the need for major transformation to attract FDI (Rwelamila 2006). Fortunately, Governments' focus on infrastructure development to eliminate urban slums, rising consumer demand, the need for new infrastructure and high economic growth in the region are driving growth of the EACS. Institutional reforms to promote the development of the EACS are also being implemented in the region (Eyisi, 2011, Structural Engineer 2011). Furthermore, future growth is predicated on projected high economic growths and the implementation of best practises by utilising high quality construction material (Frost & Sullivan 2010).

The 19 territories that constitute Eastern Africa in the United Nations scheme of geographic regions are: Burundi, Kenya, Rwanda, Tanzania and Uganda (members of the East African Community (EAC)). Others are Djibouti, Ethiopia, Eritrea and Somalia (collectively known as the Horn of Africa) Mozambique, Madagascar, Malawi, Zambia and Zimbabwe (often considered part of Southern Africa). The remaining are small Indian Ocean island nations of Comoros, Mauritius, Seychelles and French overseas territories -Réunion and Mayotte (Stock 2004). Eastern African countries are undergoing political and economic reforms to facilitate fast growth. The EAC integration with a combined GDP of US184 billion in 2010 is expected to give greater economic clout to the region, bringing tremendous benefit to member countries, particularly the smaller ones. The EAC is in a tri-partite agreement with the Common Market of Eastern and Southern Africa (COMESA) and the Southern Africa Development Community (SADC) to establish a Free Trade Area (FTA) of 26 African countries in North, South and East Africa. This gives the EAC exposure to a market of at least 500million people and a combined GDP of about US700 billion. Potential sources of instability in the region include the conflict in the DR Congo and Somalia (World Bank 2012, Eyisi 2011). The five countries selected for the study are Kenya (KEN), Mauritius (MAU), Mozambique (MOZ), Seychelles (SEY) and Zambia (ZAM).

ECONOMETRIC METHODOLOGY

Econometrics is the application of mathematics and statistical methods to economic data to give empirical content to economic relations (Pesaran, 1987). The study adopted the Vector Error Correction Model (VECM) and Panel Regression Model for the analysis. The VECM model is one of the most successful, flexible and easy to use models for the analysis of multivariate time series. VECM often provides superior forecasts to those from univariate time series models and elaborate theory-based simultaneous equations models. It is also used for structural inference and policy analysis (Hall 1994). According to Engle and Granger (1987) when a set of variables I(1) are cointegrated then short run analysis of the system should incorporate an Error Correction Term (ECT) in order to model the adjustment for the deviation from its long run equilibrium. The VECM is therefore characterised by both differenced and long run equilibrium models thereby allowing for estimates of short run dynamics as well as long equilibrium adjustment process. The panel-based VECM for this study is specified as follows.

$$\Delta LCNS_{it} = \emptyset_1 + \sum_{i=p}^{r} \beta_{11p} \Delta LCNS_{t-p} + \sum_{i=p}^{r} \beta_{12p} \Delta LFDI_{t-p} + \sum_{i=p}^{r} \beta_{13p} \Delta LGDP_{t-p} + \alpha_{11} ECT_{it-1} + \quad (1)$$

$$\Delta LFDI_{it} = \emptyset_1 + \sum_{i=p}^{r} \beta_{21p} \Delta LCNS_{t-p} + \sum_{i=p}^{r} \beta_{22p} \Delta LFDI_{t-p} + \sum_{i=p}^{r} \beta_{23p} \Delta LGDP_{t-p} + \alpha_{21} ECT_{it-1} +$$
(2)

$$\Delta LGDP_{it} = \emptyset_1 + \sum_{i=p}^{r} \beta_{31p} \Delta LCNS_{t-p} + \sum_{i=p}^{r} \beta_{32p} \Delta LFDI_{t-p} + \sum_{i=p}^{r} \beta_{33p} \Delta LGDP_{t-p} + \alpha_{31} ECT_{it-1} +$$
(3)

where $i = 1,\ldots,N$ denotes the country; $t = 1,\ldots,T$ denotes the time period; ε_{it} is assumed to be serially uncorrelated error term; ECT is the lagged error-correction term derived from the long-run cointegrating relationship.

Construction Sector (CNS); this the total market value of all final goods and services produced within the construction sector in a country during the year in USD 2005 price;

Foreign Direct Investment (FDI); is total value of inflow of FDI into a receiving country in USD within the year;

Gross Domestic Product (GDP); refers to the market value of all final goods and services produced within a country in a given within the year.

The data for the study is based on annualised 40 year period from 1970 through 2009 extracted from United Nations Conference on Trade and Development Statistics (UNCTADStat). The VECM procedure however involves modelling the series after unit root/stationarity and cointegration status of the series has been determined.

Panel Unit Root Test

The study employs five methods to perform the panel unit root test - Breitung (2000) t test; Levin, Lin and Chu (2002) t panel unit root test (LLC); Both Breitung and LLC tests assume that there is a common unit root process across the cross-sections. For these tests, the null hypothesis is that there is a unit root, while the alternative hypothesis is that there is no unit root; Im, Pesaran and Shin (2003), W-test (IPS); a Fisher-type test using Augmented Dickey-Fuller (Maddala and Wu, 1999) (ADF-Fisher Chi-Square); and Choi, (2001) and Phillips-Perron (1988) (PP-Fisher Chi-Square test); The IPS, ADF and PP tests assume that there are individual unit root processes across the cross-sections. For these tests, the null hypothesis is that there is a unit root, while the alternative hypothesis is that some cross-sections do not have a unit root.

Panel Cointegration Test

The cointegration tests for this study are performed using three main tests, namely Pedroni (1999), Kao (1999) and Johansen Fisher tests (Maddala and Wu 1999). The Pedroni (1999) cointegration test basically employs seven (four panel statistics and three group panel statistics) statistics to test the null hypothesis of no cointegration against the alternative hypothesis of cointegration. The seven component tests of Pedroni are: the panel v test, panel rho-test, panel PP-test, panel ADF-test, group rho-test, group PP-test and group ADF-test. The Kao (1999) cointegration test follows the same approach as the Pedroni tests, but it specifies cross section specific intercepts and homogeneous coefficients on the first stage regressors. In the null hypothesis, the residuals, are non-stationary (i.e., there is no cointegration). In the alternative hypothesis, the residuals are stationary (i.e., there is a cointegrating relationship among the variables). Maddala and Wu (1999) used Fisher's result to propose a method for combining test from individual cross-sections to obtain a test statistic for the full panel. Two kinds of Johansen-type tests have been developed: the Fisher test

from the trace test and the Fisher test from the maximum Eigen-value test. In the Johansen-type panel cointegration test, the lag order is set as one.

Panel Regression

Panel Regression is a regression which includes both cross sectional and time series data. Panel data may have group effects, time effects, or the both. In practice, the estimation procedure is either the Fixed Effects Model (FEM) or the Random Effects Model (REM) (Greene, 2003). The FEM is used if there are unique attributes of individuals that are not the results of random variation and that do not vary across time. The Fixed group effect model examines group differences in intercepts, assuming the same slopes and constant variance across entities or subjects. The FEM assumes that the slope coefficients are constant for all cross-section units, and the intercept varies over individual cross-section units but does not vary over time (Hsiao, and Hsiao, 2006**).** The study used FEM to analyse the differential performance of the construction sector across the five selected countries.

RESULT

Result of Panel Unit Root tests; the results of unit root test in level show that the series have unit root and are thus non stationary. The test was then rerun in their logarithmic and first difference form. The result then indicates that at 1percent all the series are stationary. All series are therefore taken as nonstationary at level but stationary at first difference I (1). The panel unit root test results are reported in table 1 for the first difference of the data.

Table 1 Panel unit root test result (first difference)

Panel series	**Null: Unit root (common unit root process)**		**Null: Unit root (individual unit root process)**		
	LLC t	Breitung t	IPS	ADF	PP
ΔLCNS	-2.70715***	1.08906	-0.89743	20.6159**	46.9999***
ΔLFDI	-13.4228***	-7.72328***	-13.9022***	282.666***	882.500***
ΔLGDP	-2.30491**	-4.38860***	-5.08350***	43.6991***	71.3419***

*, **, or *** indicates significance at 10, 5, or 1 % respectively

Result of Panel Cointegration; the summary of the Pedroni cointegration test using the assumptions of no deterministic trend indicate that only two of the seven tests statistics are significant. The Kao test suggests no panel cointegration at a 10% level of significance. However, the Johansen Fisher test suggests the existence of one cointegrating vectors at a 1%. Overall, there is statistical evidence in favour of significant panel cointegration among LCNS, LFDI and LGDP in Eastern Africa. The evidence of cointegration rules out the possibility of spurious regression problem. Table 2 shows the panel cointegration tests result.

Table 2 Panel cointegration test result for LCNS, LFDI and LGDP

r≤ 2	6.784	0.7457

*,** or *** indicates significance at 10, 5 or 1% respectively

Cointegration Vector

The cointegrating vector is normalized on LCNS. The model indicates significant positive effect of LFDI on the LCNS, while the LGDP has insignificant negative on the LCNS. For Eastern African unbalanced panel data, the long-run panel elasticity of LCNS with respect to LFDI is below unity (0.658380), indicating that for every 1percent increase in LFDI, LCNS increases 0.66percent. The Result also indicates that a 1percent increase in LGDP decreases LCNS by 0.53percent. The panel cointegration equation can be written as

LCNS= 4.972720 + 0.658380LFDI-0.533219LGDP

Table 3 Cointegrating vector for Eastern Africa

Normalizing on LCNS	**C**	**LCNS**	**LFDI**	**LGDP**
	4.972720		0.658380	-0.533219
Alpha		0.021822	-0.219904	0.004642
Loading factor		[2.20564]	[-2.67172]	[1.22872]

t-statistics in [ ]

The loading factors (coefficients of the ECT) indicate that about 2.18percent, 21.99percent and 0.46percent of disequilibrium in the system is corrected every year by changes in LCNS, LFDI and LGDP respectively. The t statistics of the loading factors for LGDP and LCNS are positive and insignificant. The t-statistics of LFDI is however, negative and significant implying two unidirectional long-run panel causality links running from LFDI to LCNS and LFDI to LGDP (see table 3). The result of the cointegrating vector confirms two significant unidirectional causalities-FDI→CNS and FDI→GDP in Eastern Africa. The FDI →CNS direction is supported by the Endogenous Growth Theorem (EGT) of Barro and Sala-i-Martin (1995) among others, that FDI promotes long run economic growth through permanent knowledge transfer (technology spillover) . The FDI→GDP direction is also supported by the FDI →growth theory (as explained by the EGT). Thus the FDI-led-CNS/GDP growth hypothesis seems applicable for Eastern African countries. Therefore based on these finding, Eastern Africa' policy makers may formulate policy to attract more FDI as means of growing their CNS/GDP.

The Fixed Effects Model

Table 4 presents the estimated results from the FEM regression. The estimate of the intercept of the model is negative and insignificant at 10percent. This means that without the regressors Eastern African countries experiences insignificant de-construction of up to 50.55percent. This also means that the regressors are able to capture most of the factors that affect the Construction Sector output in Eastern Africa

and that there are lower limits (or thresholds) of lagged CNS, FDI and GDP before positive CNS output can take place. The estimate of the country fixed effects show that three countries- KEN, MOZ and SEY have negative effects. This statistically suggests that comparatively these countries have lower CNS output given their respective FDI and GDP with MOZ being the worse. Some of the plausible reason for this below average performance of KEN, MOZ and SEY may not be unconnected to the many episode of oil price shocks (Kenya, Mozambique and Seychelles are net oil importers) political crises (Mozambique) economic recessions, Structural Adjustment Programmes and drought (Kenya, Mozambique and Seychelles) during the period 1970 through 2009 (SAPRIN 2002 and CIA 2012).

Table 4 Result of FEM

Dependent Variable: LCNS	**Cross section Fixed effect Model**		
	Coefficient	t-Statistic	Prob.
C	-0.505589	-0.855100	0.3937
LCNS(-1)	1.238553	14.50051	0.0000
LCNS(-2)	-0.298117	-3.353425	0.0010
LFDI(-1)	0.015505	1.819855	0.0705
LFDI(-2)	-0.002197	-0.265692	0.7908
LGDP(-1)	0.197944	0.838524	0.4029
LGDP(-2)	-0.133095	-0.577704	0.5642
KEN	-0.008760		
MAU	0.018238		
MOZ	-0.022107		
SEY	-0.006073		
ZAM	0.017685		

CONCLUSION

The study finds significant long-run equilibrium relationship among CNS, FDI and GDP. The cointegration vector indicates two significant unidirectional causal effects FDI→CNS and FDI→GDP; that is FDI makes significant causal impact on CNS and GDP. This implies that greater FDI inflow will help accelerate growth in CNS and GDP in East Africa. The study recommends that policy makers in East Africa should improve investment climate to attract greater FDI inflow for sustained growth of the EACS and the economy. The FEM suggest that CNS in KEN, MOZ and SEY performed poorly compared to MAU and ZAM. For the construction lagging countries (i.e. KEN, MOZ and SEY) the study recommend deepening reform for greater FDI inflow and strengthening the capacity of EACS to benefit from FDI inflow to accelerate growth.

CASE STUDY: THE IMPLEMENTATION OF A PERFORMANCE METRIC SYSTEM IN A CAPTIAL IMPROVEMENT ORGANIZATION.

Anthony J. Perrenoud[1], Brian H. Stone, Kenneth T. Sullivan[2], John Savicky[1]

[1, 2] *Performance Based Studies Research Group, Arizona State University, PO Box 870204, Tempe, AZ 85287*

ABSTRACT

A capital improvement department of one of the largest universities in North America provides a case study for implementing a performance metric system. The absence of past and ongoing project performance data leaves a capital improvement organization without the essential metrics needed to evaluate the organizations efforts and provide transparency in areas of deficiencies. Collecting project metrics is deemed essential to improving project efficiency with regards to completing projects on schedule and on budget. The project data of numerous ongoing and completed construction projects are captured through the development of a weekly risk report. Partnering vendors are required to capture the performance measurements in the weekly risk report and submit weekly to provide updated project data to the organization. This data is combined to provide a report to the organization executives of overall project status, including in progress projects, and areas in their processes that require additional focus.

Keywords: capital improvement organization, measurement implementation, performance metrics, qualitative metrics, university.

INTRODUCTION

Frederick Taylor, an early twentieth century management expert, stressed the importance of metrics while he developed his popular "scientific management", his theory concluded that deductive reasoning with data collected through experimentation and observation creates greater efficiency within organization processes (Love et al., 1999). Since Frederick's early conclusion, performance metrics have evolved with in many successful organizations and provide the statistical knowledge in which leadership is able to make more informed decisions. Two distinctive categories of measurement are available and when combined create a clear picture in which one can gauge an organizations success: "Quantitative Metrics" focus more specifically with production numbers, cash flow, and statistical numbers, these statistical metrics alone are inadequate representation of a company's performance; "Qualitative Metrics" are the intangible results that capture the

[1] aperreno@exchange.asu.edu
[2] Kenneth.sullivan@asu.edu

level of satisfaction with the process and products and they have been found to be equally important in understanding company performances (Kaplan & Norton, 1992; Kagioglou et al, 2001). As the benefits from performance measurements have been recognized in the last century, numerous measurement implementation processes have been created and thousands of papers have been published on the importance of measurements (Bassioni et al, 2004).

One industry that has struggled to implement qualitative gauges within their organizations has been the construction industry (Egan 1998). Construction organizations continue to rely on quantitative measurements alone when accessing their progress, this project specific data or short term data does not allow an organization to gauge the overall level of quality or satisfaction of its long term efforts (Kaigioglou et al, 2001). In 2005, a capital improvement organization in one of the largest universities in North America found itself without performance measurements of the organization's long term goals. This paper provides a case study of an organization's attempt to capture both quantitative and qualitative information to assist their stake holders develop the efficiency of the organizations effort.

Performance Measurement

Performance measurements in the built environment are described as "a quantifiable, simple, and understandable measure that can be used to compare and improve performance" (Pitcher, 2010). Pitt and Tucker (2008) explain the three reasons for measurements as: 1) to ensure the achievement of goals and objectives; 2) to evaluate, control, and improve procedures and processes; and 3) to compare and review the performance of different organizations, teams, and individuals. Metrics have also been found to assist with providing organizations with organized customer ratings, reviews and suggestions (Love & Holt, 2000).

When applied to organizational goals with industry competition, it is closely tied to a benchmark set or initial measurements and used longitudinally to demonstrate progress over time. It can be effectively stated that measurement at the organizational level is "The systematic process of measuring an organization's performance against recognized leaders for the purpose of...superior performance when adapted and utilized" (Pitcher 2010).

Two limitations are often seen with performance metrics: first, metrics are retrospective, with markets frequently changing, continuous performance metrics are necessary for it to be meaningful to the current climate as past data reflects past markets (Halachmi, 2005; Busco et al, 2006); and second, comparable benchmarks are often unavailable to contrast company performance, competitors reluctance to release proprietary information forces organizations to place benchmarks from past metrics or individual goals (Kaplan and Norton, 1992). Both limitations impacted the case study that is presented below and required additional effort from the organization to improve the significance of the metrics.

Current Construction Measurement Environment

The construction industry has many difficult variables when gathering measurements as it usually tends to focus on short term gauges (Love & Holt, 2000). With such a high variance between projects most construction organizations are only able to measure a specific project and unable to compare them to any past or future projects, these typical on-time, on-budget and satisfactory measurements alone are inadequate to gauge a construction company (Chapman et al, 1991). Organizations that are responsible for multiple construction projects have not produced a measurement methodology that can track the quality, social impacts and human factors that are included in qualitative measurements (Love & Skitmore, 1996).

A 2008 extensive review of more than 4,500 articles on performance measurements within construction found the inability of the industry to find common ground with metrics, only 42 articles had actual collected data with a construction organization and out of those 42 only 16 had seen any improvements from performance information (Egbu et al, 2008). Amaratunga and Baldry also recognized the lack of concrete evidence that the concepts of performance measurements are utilized in the build environment (2001). The author's own literature review of numerous research papers found no methodologies that can be used by a construction organization to develop a performance measurement system that can capture multiple project data.

Implementation of Measurements

The planning phase of implementing a metric system within an organization is critical due to the change of environment that will be created within the organization and also the obstacles that will impede a system from succeeding. The employee's environment within an organization will change when introducing measurements, as part of Mayo's (1949) measurement research, it was summarized that worker productivity increased with the psychological stimulus of being shown individual attention, feeling involved, and being made to feel important, and in another section, "Employees are more productive because the employees know they are being studied". Creating a measured environment alone can motivate employees to perform better for a period of time, but for continuous improvement, measurements must be implemented and managed efficiently within the organization (Halachmi, 2005). Implementing metrics is a difficult task, planning can help minimize the impact of six obstacles that are common with creating metric systems: 1) a company's inability to define their operation process; 2) a company's inability to relate their process to acceptable performance; 3) apprehension of misrepresenting performance; 4) apprehension of poor performance; 5) misinterpreting the measurements; 6) and collecting the wrong or unnecessary metrics (Zaire, 1996).

During the initial setup of a metric system critical information must be identified, analyzed, and prioritized for the system, management should also be able to understand how the metrics will be of benefit to the organization. While gathering the most critical metrics in the beginning Kaplan and Norton (1992) suggest asking four questions for focusing on areas that can improve:

1. Financial: how do we look to shareholders?
    - Examples: profits on the project, overall cost of change orders, cost of mistakes, and costs due to delays.

2. Customer: how do customers see us?
   - Examples: client product satisfaction, client satisfaction with cost management, schedule management, close out process, communication, and risk management.
3. Internal Business: What must we excel at?
   - Examples: internal process performance, employee process satisfaction, and safety processes.
4. Innovation and Learning: Can we continue to improve & create value?
   - Examples: recognized areas of improvement, lessons learned, and opportunities for learning.

Love and Skidmore (1996) also present six common characteristics that should receive focus to achieve effective performance measurement systems:

1. develop an organization strategic plan with goals that has been established and agreed upon;
2. include both financial and nonfinancial business measures;
3. understand how benchmarks will be provided for comparative measurements;
4. clearly understand the organizations laws that govern the organizations behavior both within the organization and the industry';
5. present the results of the measurements consistently to develop a established workplace to encourage consistent reactions to the metrics; and
6. have the full support of the leadership and drive the metric system from top to bottom while fostering a sense of belonging and responsibility in the work staff with the results.

CASE STUDY

Capital Planning and Project Management (CPPM) at the University of Minnesota is responsible for all new construction and renovation of existing buildings on the two main universities campuses. The combined staff consists of a director, senior project managers, project managers, and support level staff that are responsible for the procurement of vendors, ensuring their clients receive the desired scope, and assisting the vendors to comply with the codes and requirements at the university.

In 2005, the leadership of CPPM found itself unable to report basic performance metrics which left management second guessing their perceptions of the group's performance. Understanding what impacts caused projects to be delayed or over budget was limited to individual project reports. Managements perception was that projects were being completed thirty percent over budget and thirty percent behind schedule. Without a comprehensive metric system collecting data of all the projects, their perceptions of the reasons for delays and high cost increases were not conclusive and consequentially left management skeptical of contractor's performance. CPPM looked for ways in which they could begin capturing project performance metrics to help minimize overall project impacts. During 2005, CPPM was introduced to a group affiliated with Arizona State University (ASU) that would assist with implementing performance measurements in the construction and renovation of its campus buildings (Sullivan et al, 2007).

University's Implementation of Performance Measurements

Initially, processes for implementing the metrics needed to be defined, CPPM slowly began to test pilot capturing measurements on individual projects. Project processes needed to be defined so that measurements could capture deviations from process in the project, this required additional preplanning before each project. Individual project pre-planning required that the vendors would present the cost and schedule for completing projects, the metrics would capture any changes to the set plan, who or what caused them, and their ability to manage the project impacts not foreseen in the initial plan. The vendors would also be required by the contract to capture these metrics in a report that was submitted to CPPM weekly.

During the first year, while defining the processes that would be used to capture the metrics, CPPM developed a strategic plan to assure that the group would achieve its goals with capturing the performance measurements. The strategic plan set in the beginning was modified over time from the group's experiences and lessons learned to assure that the group was achieving beneficial goals and was minimizing any employees concerns regarding measurements. As CPPM was able to see how they would be able to capture different indicators they were able to effectively refine their metrics. Their metrics would be captured in weekly reports and would be combined into a summarized report to assist management for effective organization management.

Weekly Risk Report

To capture the individual project metrics, CPPM requires that vendor project managers maintain a weekly report that is set up using Microsoft Excel template. This Excel file referred to as the "Weekly Risk Report" (WRR), is set up at the beginning of each project and contains basic project information and the vendors planned schedule and project cost (Sullivan et al, 2006). The vendor manages the WRR and captures any risk to the project that might impact the cost or schedule of the project and the vendors solution to minimize the impact of the risk; each risk is categorized in the WRR to identify who and what caused the issue. The CPPM project manager responsible for the project will rate the vendor's ability to minimize each risk to show their satisfaction of the vendor's performance. Once a project is completed the WRR will summarize all issues that impacted the project cost or schedule and will identify what were the major reasons that the project was not able to go as initially planned.

The WRR purposes include:

1. provide basic project information;
2. tracks the progress in the projects schedule;
3. tracks all project risks to the project and how they will be mitigated;
4. tracks actual schedule delays and cost increases;
5. tracks who causes schedule delays and cost increases;
6. tracks contractor's performance with all risks of project;
7. assigns a level of severity to the project from the projects impacts; and
8. captures qualitative satisfaction ratings of vendor performance.

For CPPM to quickly understand how well a project is being managed a "risk rating" is assigned to the project in the WRR, the WRR calculates the risk rating by combining the cost increases, delays, and client satisfaction. Greater cost increases, schedule delays, and poor client satisfaction ratings will result in a higher risk rating; the higher the value of the risk rating the greater concern should be focused on the projects performance. These metrics collected in the WRR are easily transferred to an overall report that combines these metrics to portray the overall department efforts.

Directors Report

On average CPPM has fifty ongoing projects, by combining the individual WRR's into one Excel file called the "Director Report" that management is able to understand the overall measurement of the organization from both projects that are in progress and those that have been completed in the past. Figure 1 depicts how the WRR's for the individual projects are all captured in the Directors Report.

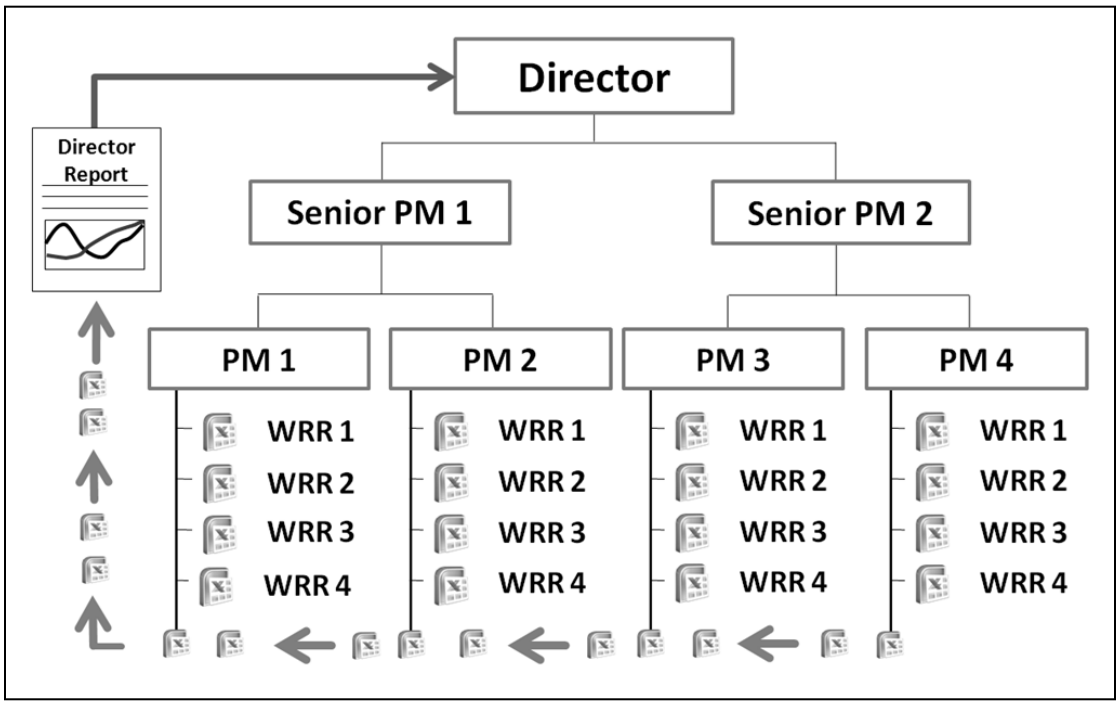

Figure 1 - Directors Report Collecting Individual Project Metrics

The Director Report is provided to the management team monthly to provide consistent performance metrics that can assist management and allow employees to understand areas which needs more focus. The Director Report contains eight different analyses that automatically update when the new weekly reports are submitted from the vendors. The following analyses are found in the Director Report:

1. Executive - is an overview of all completed and ongoing projects performance metrics and provides analysis of the metrics such as cost increases of the projects and the parties responsible for the increases. After five years of collecting data CPPM found that their clients were responsible for 74 percent of cost increases,

CPPM was responsible for 18 percent, designers were responsible for 8 percent, and contractors were responsible for 0.03 percent of cost increases.

2. Senior Project Managers – this analysis breaks down the projects that are under the two senior project managers responsible for the project managers.
3. PM – this analysis provides individual performance measurements for each project manager.
4. Risk Impacts – this analysis breaks down all the risks and their impacts to the projects, collected in twelve different subcategories such as: Client impact – scope change; CPPM impact – codes and permits; Contractor impact – sub/supplier issue; and unforeseen impacts.
5. Vendors – this analysis includes performance metrics on all contractors that have worked with CPPM on University of Minnesota projects.
6. Top 10 Risky Projects – the risk ratings that are assigned for each project on the WRR's are compared against all ongoing projects so management can see which projects have the most risk currently, so management can quickly see where additional support is needed.
7. Close Out – this analysis provides the overall close out ratings of the projects. At the end of each project a close out survey is completed and provides qualitative measurements of the vendors and projects performance. Satisfaction ratings are provided on the vendor and their ability to manage the project, cost management, schedule management, level of communication, quality of work, and overall professionalism.
8. Year to Year – analysis provides yearly performance metrics that can be used as benchmarks for the group to compare their ongoing progress.

CONCLUSION

In conclusion, the University of Minnesota capital improvement organization, CPPM, provides a case study in which a similar organization can follow to capture both quantitative and qualitative metrics of ongoing and completed construction projects. The implementation of the Weekly Risk Reports provided a way in which CPPM could collect the metrics through the contracted vendors and required very limited resources in their organization. The compiling of the WRR in the Director Report provides CPPM with overall performance measurements of their groups efforts to assist decision making. Because CPPM's full management team supported collecting performance metrics they were able to overcome obstacles with not having comparable benchmarks, issues with reluctant employees, and metrics that were beneficial in changing economic climates. Within a couple of years CPPM was able to provide beneficial performance metrics that were previously inaccessible and establish a consistent environment of accountability.

ABSTRACT

Ever increasing competition in the global market has caused organizations in all industries strive towards greater effectiveness. Although individual companies may pursue effectiveness via a number of avenues, nearly all efforts to improve performance necessitate some level of organizational change implementation and management. Since much research exists in this field, the literature is reviewed to identify key change management principles from leading organizational change implementation models. An organizational change effort at the University of Alberta is examined, where an owner-driven quality program, the Best Value Model, is being implemented in the procurement and facilities and operations departments. A case study is presented in the University's pilot project implementation of best value through the procurement and delivery of a large-scale custodial services contract. The success of this organizational change effort is retrospectively assessed in terms of the leading literature principles of change implementation models. This is significant because it provides a real-time case study to further validate the existing literature knowledge in the field of organizational change management.

Keywords: best value, implementation, change management, organizational change, performance measurement.

INTRODUCTION

As global competition continues to become more disruptive, organizations worldwide are impacted by an accelerated pace of change (Hallencreutz and Turner 2011). Change efforts have become commonplace to sustain continual improvement in organizational performance (Blair and Meadows 1996). Yet while the need for successful change management practices has never been greater, implementing change is an extremely difficult task often met with failure. Many sources suggest that more than half of all change efforts fail to accomplish their original intended purpose (Choi and Behling 1997, Maurer 1996, Pascale, Millemann, and Vakolar 1997, Self and Schraeder, 2009). Balogun and Hope Hailey reported the failure rate for change

[1] Kenneth.Sullivan@asu.edu

initiatives to be as high as 70 percent (2004). In light of this fact, successful change management practices are rapidly becoming a required skill of managers in all industries (Todnem 2005).

In response to this trend, a review of the literature was conducted to identify key change management principles intended to increase the success rate of organizational change implementation efforts. A successful case study of change management is presented to describe successful practices, challenges, and the overall life cycle that impact organizational changes. This case study was also analyzed according to its adherence with suggested change management principles from the literature to provide further validation of successful change management practices.

LITERATURE

Organizational changes efforts are generally comprised of three main components (Kanter *et al*. 1992): the 'what' to change (including diagnostic tools to identify what problems and potential solutions exist), the 'how' to change (implementation models), and 'when' to change (whether change is needed and likely to be successful). Answering the question of 'what' to change can be challenging, as organizational changes occur in many forms including restructuring, reengineering, mergers and acquisitions, downsizing, and the introduction of new technologies (Walker *et al.* 2007). More recent notions suggest that what organizations really need to do is create a culture of agility or resiliency to encourage continuous innovation and adaptation in pursuit of a generalized set of objectives or principles (Denhard and Denhardt 2001, Weeks 2009). Although important, the questions of 'what' to change and 'when' to change were not addressed in this paper; rather, the focus was on 'how' to implement change. It is worth noting, however, that the presented case study followed the more recent pattern of working toward a set of generalized strategic objectives.

No matter 'what' the change, the process of successfully managing the implementation process is challenging. Many models of organizational change have been presented in the literature to describe the general steps within the change process, obstacles that are likely to be encountered, and strategies for success. No universal, step-by-step, all-purpose model can exist because not all changes are equivalent and various contingencies are critical factors: changes vary in scope, scale, operation level, targets, and objectives. Yet organizational change models do provide valuable principles that may benefit change managers in a wide variety of situations.

Change Management Models

Five change management models were reviewed to develop an understanding of recommended change management principles. The chosen models were selected due to their prominence, comprehensive nature, and varied research dates to gain a broader perspective into the existing knowledge within the field of organizational change research. The reviewed models included: Beer, Eisentat, and Spector 1990, Kanter *et al*. 1992, Kotter 1995, Armenakis *et al.* 1999, and Luecke 2003.

Change Management Principles

The key change management principles contained each within model were tabulated to develop an understanding of important practices to increase the success of organizational change efforts. Twelve leading principles were identified within the reviewed models and the frequency with which each change management principle appeared in the literature models was noted (see Table 1).

Change Management Principle	Beer, Eisenstat, Spector 1990	Kanter *et al.* 1992	Kotter 1995	Armenakis *et al.* 1999	Luecke 2003	Literature Frequency
Create Motivation for Change	X	X	X		X	80%
Analyze Problems & Needs	X	X		X	X	80%
Identify Solutions & Vision	X	X	X	X	X	100%
Establish Core Team Leadership	X	X	X		X	80%
Secure Executive Support	X	X	X			60%
Strategic and Tactical Planning		X				20%
Communicate Change Message	X	X	X	X	X	100%
Overcome Resistance	X		X	X		60%
Implement on Test Basis		X		X	X	60%
Expand to Intended Scale	X		X	X	X	80%
Transition to Institutionalization	X	X	X	X	X	100%
Long-Term Measurement					X	20%

Create Motivation for Change. Change efforts require coordinated efforts by a multitude of people, and these people are more likely to be engaged when there is a sense of urgency to motivate them (Kotter 1995). Luecke (2003) suggests a good rule of thumb is that the goals of the change cannot be achieved unless 75 percent of managers believe they must change from the status quo.

Analyze Problems and Needs. A broad review of the business is undertaken to come to a "joint diagnosis" of the roots of the current problems (Beer *et al*. 1990). Kotter (1995) observed that successful changes generally start with frank discussions about unpleasant facts where multiple parties are engaged.

Identify Solutions and Vision. The vision is a "picture of a destination aspired to, an end state to be achieved via the change" (Kanter *et al.* 1992). The vision is not necessarily a fully developed strategy, but is intended as the general purpose or goal for the movement; oftentimes, the details are worked out during implementation.

Establish Core Team Leadership. A visible leadership or Core Team must act as the leading change agents to implement the change. It is critical that these personnel have the operating know-how to accomplish the goals (Luecke 2003). Armenakis *et al*. (1999) stated that the most important trait of Core Team leadership is credibility in the eyes of other organizational members.

Secure Executive Support. Executives often control resources needed by the Core Team implementers and their backing is crucial (Kanter *et al.* 1992). Executive also supporters also wield the clout to further legitimize the change.

Strategic and Tactical Planning. The strategy is important to clarify high level goals, identify who is involved, and define roles and responsibilities of participants (Kanter *et al.* 1992). Tactical planning of specific projects or areas to change is important not only to help foster learning, but also to create short-term wins to maintain momentum and bring recognition (Kotter 1995)

Communicate Change Message. The change message is critical to helping implementation and should answer five key questions: (1) Is the change really necessary? (2) Is the specific change being introduced appropriate? (3) Can I/we successfully implement the change? (4) Is there high level, long term support for the change? (5) What's in it for the change recipients? (Armenakis *et al,* 1999).

Overcome Resistance. Resistance often crops up as employees feel shock, fear of the unknown, mistrust, fear of failure, loss of power, lack of perceived rewards (Armenakis *et al.* 1990, Luecke 2003). Education and communication to address these issues is an important responsibility of the Core Team change agents.

Implement on Test Basis. Starting change on the periphery enables flexibility, experimentation, and improvement before impacting the whole organization (Luecke 2003). Individual units or projects essentially become "developmental laboratories" for the change (Beer *et al.* 1990).

Expand to Intended Scale. Building on initial implementation and short-term wins aids the diffusion process. Beer *et al.* (1990) recommend letting each department or expansion area "reinvent the wheel" to find the most optimal way to integrate the change into their environment.

Transition to Institutionalization. Institutionalization is the condition where the change becomes "the way we do things around here" (Armenakis *et al.* 1999). The transition begins when the change has become more entrenched, the right people are in place, and the new team work setup is functioning (Beer *et al.* 1990).

Long-Term Measurement. Kanter *et al.* (1992) stress the importance of sustaining the change by continuously providing feedback mechanisms to show organizational performance in terms of results metrics (showing we have "done it") and process metrics (showing we are doing the right things to accomplish "it").

BEST VALUE IMPLEMENTATION CASE STUDY

The University of Alberta (UA) recently partnered with ASU to implement the Best Value Model. Located in Edmonton, UA is a large research intensive university with over 38,000 students and an annual budget of $1.7 billion. Results of the implementation strategy and progress to date are shared as a case study of change management, with the purpose of noting areas of success and difficulty while also shedding light on the life cycle a real-time organizational change effort.

The Best Value Model is an owner-driven program that aims to improve quality of projects throughout the contract lifetime. The model was initially developed at Arizona State University and has been tested on more than 900 projects in $4.7 billion in the services and construction industries with a 98 percent client satisfaction rating.

Initiation, Set Up, and Planning

UA was introduced to Best Value 5-6 years before they made the decision to proceed with implementation. After their initial introduction, the UA analyzed issues and opportunities present in their environment, ultimately identifying needs that provided motivation for members of the senior executive team to pursue Best Value. Once UA was partnered with the Best Value educators from ASU, they quickly moved to form a Core Team to function as leaders of the internal implementation effort. Key leaders of the Core Team included the Director of Supply Management Services and Director of Facilities and Operations, who effectively formed an implementation partnership between their two departments.

The Core Team met with ASU and formulated a strategic and tactical plan to accomplish specific goals. The vision for this effort was to improve organizational effectiveness via four strategic objectives: (1) become a measured organization, (2) increase preplanning and risk minimization through accountability, (3) procure and contract with high performing vendors, and (4) increase performance throughout

contract lifetimes. In order to accomplish this strategic vision, the tactical plan was to implement Best Value on select contracts as pilot projects to function as "hands on" learning experiences for the Core Team and additional change recipient members. If individual project were met with success, the University would then move forward towards creating more formal Best Value programs. This vision was shared with UA organizational members via education touch points and project planning meetings. Preliminary educational outreaches and pre-proposal meetings were conducted with external vendors to introduce them to Best Value concepts prior to their direct involvement with Best Value pilot projects.

Pilot Project Implementation

The first project to implement Best Value at the University of Alberta was for delivery of campus-wide custodial services. To prepare the vendor community for the philosophical shift in management approach, UA initially conducted information sessions for potential vendors prior to issuing the Request for Proposal. Information sessions were also provided for internal stakeholders. These educational outreaches helped to create a common level of understanding about the new business approach, address questions and concerns to increase stakeholder comfort, and orient participants in how to be successful in this new environment.

This pilot project was an intriguing change management case study due to the fact that the incumbent vendor from the previous contract participated, and was ultimately successful, in the selection process. The incumbent demonstrated high performance on the previous contract, as evidenced by their perfect 10 out of 10 past performance ratings (for their firm and project management personnel). Out of the eight respondent vendors, the incumbent achieved the highest evaluation score in all evaluation criteria (overall cost, risk plans, project team interviews).

The incumbent vendor then moved into application of new Best Value management principles into the pre-planning and execution of the contract. Successful implementation of these principles was an indicator of observed organizational change within the environment of a single large-scale contract. The fact that the incumbent vendor was selected made this pilot project an interesting case study in change management. The same vendor and client were able to work together successfully not only to operate successfully within an entirely new management structure, but also to achieve impressive project results. Three key differences in the new management principles marked this process as a distinct departure from 'traditional' practice:

Role Reversal. The purpose of the Best Value selection process is to identify and select the highest expertise team among the vendor community. With the understanding that the vendor is an expert in their field, better allocation of risk and responsibility are placed on the vendor for project planning, delivery, and measurement. In this new role, the vendor is both empowered and expected to bring value through vendor-generated project solutions.

Pre-Planning. Formal pre-planning with both parties enables coordination and alignment of expectations before work commences. A vendor-generated plan is produced which integrates client concerns, risk identification and mitigation, clear scope definition, defined interaction points between parties, and a full schedule of deliverables during project execution.

Performance Measurement. During the project, actual performance of the project team is measured against the plan set during the Pre-Planning phase. Each week, the vendor tracks unforeseen risks and any other impacts and manages mitigation strategies. The final project rating is affected not only by project performance but also timely and accurate risk measurement.

Pilot Project Results

Overall, implementation of the Best Value Model was extremely successful during pilot implementation at the University of Alberta. Project successes achieved were threefold: First, UA feared that competition on the RFP may be limited, in part due to the implementation of a new procurement and management model. Initially it was thought that UA would only be able to attract two local vendors to be able to bid on the ten-year, campus-wide contract. In fact, fifteen vendors expressed interest during early education stages and eight eventually proposed on the project. Second, initial estimates placed the project budget at $70 million over ten years, yet upon award the total contract value was estimated at $62 million. Up front savings of half a million dollars per year made the procurement process a huge success. Third, the role-reversal to greater enable vendor-generated solutions resulted in the awarded vendor taking full responsibility for quality assurance inspections, which allowed UA to reallocate three full time employees, providing further internal savings.

The Core Team involved in the pilot implementation project established regular meetings with executive sponsors. These meetings served as executive "touch points" to inform them of implementation progress, successes realized, and barriers encountered that the executives could help the team overcome. By communicating the success of the initial pilot project to their executive sponsors, the Core Team secured two additional years of funding to support the greater implementation and expansion of Best Value in their organization. The strategy of spreading good news stories (in addition to ongoing education efforts) was also applied to other stakeholders and the community as a whole to help minimize resistance.

Future Change Implementation Efforts

Following the success of the initial pilot project, the change management strategy at UA is planned to first include additional isolated pilot projects. The tactical plan is to run two additional pilot projects that will function as additional learning experiences for UA's implementation process and provide additional success stories. Strategically, these projects were selected to involve different industry communities (construction, architectural and consulting) in addition to the services community engaged on the first pilot. Furthermore, the Core Team has assigned different UA implementation personnel than those involved with the first project to begin expanding the internal exposure within their organization.

Beyond these pilot projects, future expansion is planned to include a full program of construction management services for all projects valued at $2.5 million and below, as well as a large-scale, campus-wide IT project. These programs will function as the main expansion efforts to transition Best Value into an institutionalized tool available to the University of Alberta for years to come. The long-term vision also includes a website or other communication platform to broadcast success in continued fulfilment of UA's strategic objectives. Performance measurements and results are envisioned to be reported on both the project and organizational levels.

CHANGE MANAGEMENT PRINCIPLES IN ACTION

The case study implementation of an advanced management system into a large university environment has been met with high levels of success from a change management perspective. This success has been realized at both the project and organizational levels, following an implementation strategy where individual projects are used to provide educational opportunities and facilitate "hands on" learning of executive sponsors, Core Group implementation leaders, and change recipients.

The presented case study of change management efforts to implement the Best Value Model at the University of Alberta was retrospectively analyzed to identify adherence to the change management principles espoused in the current literature body of knowledge. The University of Alberta's implementation effort did not actively follow the process steps and principles of any change models from the literature; rather, the self-contained experience of change management researchers at ASU was relied on to ensure the implementation process ran smoothly. The successful nature of the change effort to date provides the opportunity to analyze whether change management principles were unknowingly adhered to or ignored (see Table 2).

Table 2. Case Study Adherence to Change Management Principles

Number	Change Management Principle	Best Value Case Study
1	Create Motivation for Change	X
2	Analyze Problems & Needs	X
3	Identify Solutions & Vision	X
4	Establish Core Team Leadership	X
5	Secure Executive Support	X
6	Strategic and Tactical Planning	X
7	Communicate Change Message	X
8	Overcome Resistance	X
9	Implement on Test Basis	X
10	Expand to Intended Scale	Planned
11	Transition to Institutionalization	Planned
12	Long-Term Measurement	Planned

Of the twelve major change management principles suggested in the literature, nine have been implemented at the University of Alberta. The remaining three principles (expanding to a full change program, transitioning to institutionalization, and establishing long-term measurement) have already been planned as future activities in the continued change effort. The presented case study, which has seen great success to date, unknowingly followed the critical change management principles presented in the literature, further validating their applicability.

CONCLUSIONS

Successful change management practices have become a critical component to organizational success in maintaining long-term competitiveness. Academic papers have long noted the difficulty in implementing organizational change, with studies reporting failure rates to be alarmingly high. Change management principles have been recommended in the literature to increase the likelihood that implementation efforts are successful. An advanced management system called the Best Value Model has been applied to numerous projects and organizations and has been documented to

significantly improve quality and efficiency. The case study implementation of Best Value at the University of Alberta is a story of successful organizational change implementation which has resulted in tangible benefits to the organization. Analysis of this case study shows that the successful change management efforts at the University of Alberta did indeed follow the major change management practices proposed in the literature. Further testing at the University of Alberta is recommended to reach full program implementation and eventually lead to long-term sustainability and institutionalization. Yet current results provide further validation of the existing body of knowledge and provide a compelling case that utilizing certain change management principles correlate positively with successful change effort results. This analysis demonstrates the opportunity to educate executives and project managers in industry to help them become successful change managers.

ABSTRACT

Inner city, confined site construction is quickly becoming the norm within the construction sector. The aim of this paper is to identify and document the effect, if any, that a confined construction site environment has on the productivity of on-site personnel. In order to compile the relevant information and attain appropriate results on the matter in question, a qualitative analytical approach is adopted. This process incorporates multiple cases studies from Ireland, Northern Ireland and USA. From the resulting case studies, a minimum of three individual interviews and focus group seminars are conducted to aid in the collection of the data while also assisting in the confirmation of the factors identified from a critique of the relevant literature. From the resulting case studies and discussions, a list of the key issues pertaining to the on-site productivity of personnel emerged and is documented as follows; 1) Overcrowding of personnel at workstations, 2) Lack of space for the effective movement of personnel on-site, 3) Numerous trades working within the one space on-site. Through identifying the issues highlighted and proactively mitigating or eliminating the factors detailed, on-site management professionals can strive to ensure maximum productivity from the industry's most important resource – people.

Keywords: city centre development, overcrowding, project management, site management, space.

INTRODUCTION

With the migration of populations from rural environments to urban centres, particularly over the last decade (United Nations, 2008), the need to develop these urban city centre areas also increases. This is predominantly due to the need to facilitate the services required by this influx of population (Waddell, 2002). With figures illustrating increased population densities throughout Europe, construction within this geographical area is set to face continued renewal and expansion (Gale and Fellows, 1990). With the development of these spatially restricted centres, there are numerous key points noted in the successful delivery and completion of inner city confined sites. Some examples include increased material management (Spillane, *et al.,* 2010; 2012), overcrowding (Singer, 2002) and increased health and safety (Spillane, *et al.,* 2009; 2011a; 2011b). But fundamental to this is the effective

[1] j.spillane@qub.ac.uk

utilisation of the industry's most important resource – its people (Egan, 1998). Winch (2010) indicate that personnel account for a significant proportion of the costs attributable to a project while Druker and White (2007) outline that effective personnel management is often undervalued, hence, there is a high possibility of underutilisation and thus, reduced productivity of this important resource in the industry. Where interruptions occur in the fluidity of personnel output on-site, there is a possibility of uneven flow of work, thus resulting in reduced productivity (Thomas, 2000). In order to sustain assigned project completion parameters, compressing the project schedule is sometimes suggested, but often with adverse consequences (McDonald and Zack, 2007). However, the construction industry is renowned for being notoriously unproductive, particularly in relation to labour productivity (Koskenvesa, *et al*., 2010), thus it has received attention from various academics vying to resolve the issue at hand (Koskela, 1992; Thomas and Napolitan, 1995; Ballard, 2002; Ballard and Howel, 2003). In order to assist on-site project managers with the onerous task of effectively managing the construction process, it is beneficial to identify the impact the site environment has on personnel productivity on-site. Through the use of a qualitative approach including individual and focus group interviews coupled with the inclusion of three case studies, it is possible to gain an insight into industry perceptions on the issue.

Three case studies are identified for inclusion in the research, with a minimum of three on-site professionals questioned with regards personnel productivity, in respect to their particular confined construction site. By introducing mind mapping, it is possible to identify and disseminate the impact of constructing sometimes intricate structures in an environment where space is often to the fore, particularly in relation to being a finite resource requiring effective, continuous management (Tommelein and Zouein, 1993). In documenting the factors which impact personnel productivity on a confined construction site, it will aid on-site project managers to identify the critical factors and in doing so, will asset in the implementation of mitigation measures to reduce or eliminate the resulting reduction in productivity on-site. Thus, through ensuring that optimum levels of productivity are not only achieved but also sustained, the possibility of achieving successful project completion is ever more attainable.

LABOUR PRODUCTIVITY

Labour productivity can be defined subjectively in analytical form or in a broader sense. One of the more universal definitions is provided by Hanna, *et al.,* (2008), where, from an economists point of view, labour productivity is defined as the ratio between inputs; such as labour, material and plant, and outputs; the value of completed work. This view is also shared by Schwartzkopf, (2004) who elaborates on the definition by highlighting the various methods of labour productivity. These include 'direct methods' such as percentage of work complete, 'work sampling' which involves reviewing the work being undertaken over time. In addition, 'Craftsman questionnaire sampling' and 'earned value methods' are also included in the methodology reviewed. From a construction manager's point of view, productivity can be defined as the 'ratio between earned work hours and expended work hours' (Hanna, 2008). Within labour productivity, there are a number of factors which have been identified as detrimental to labour productivity on-site. Some of these factors include over manning (Hanna, 2007), stacking of trades (McDonald and Zack, 2007),

lack of materials (Thomas and Napolitan, 1995), extended overtime (Hanna, *et al.,* 2005), changing working time (Ibbs, 2005) and shift work (Hanna, *et al.,* 2008), but to name a few. However, one of the more pronounced factors adversely effecting personnel productivity is that of the construction schedule (Ritz, 1994) and more particularly schedule compression (Thomas, 2000) – a methodology which outlines the systematic approach in the monitoring and control of productivity.

Productivity of labour has proved a fickle topic, particularly in regards to the construction sector. In the case where additional resources are introduced to a particular work package, Hanna, *et al.,* (1999) argues that the resulting stacking, particularly of trades, may result in inefficiencies. Tse and Love (2008) share the viewpoint that overtime and shift work are more cost effective ways of schedule acceleration although it must be noted that a decline in productivity has been linked where overtime is introduced on a long-term basis and thus, should only be used as necessary. In addition, Ibbs (2005) compounds the issue by documenting that late change and lack of notice exasperate the problems in regards to productivity and therefore must be avoided where possible. Overcrowding is one of the core factors attributable to confined site construction (Spillane, *et al.,* 2011b) with both personnel (Cotton, 2009) and plant and equipment proving detrimental (Uher and Loosemore, 2004; Kim *et al*., 2005). Makulsawatudom and Emsley (2001) establish, during a study of factors affecting craftsmen's productivity, that overcrowding is ranked as the fourth most influential factor, with only lack of materials, lack of equipment and incomplete drawings causing a greater loss in personnel productivity on-site. Makulsawatudom and Emsley's (2001) report found that project managers rank overcrowding as the sixteenth most significant factor, thus further compounding the issue and the severity of the research in question. Finally, a leading study by Thomas, (2006) concludes that overcrowding is directly correlated to craftsman's productivity, but in order to assist in associating these results with that of a confined site construction, it is necessary to review the findings and to consider the results in relation to that of a spatially restricted environment.

METHODOLOGY

In order to achieve the research objective, a primarily qualitative approach is adopted. Firstly, a literature review is conducted on the topic of personnel productivity, with particular emphasis on the construction sector. Secondly, to capitalise on the information acquired along with verifying the factors identified, while also eliciting further possible factors, three case studies are identified for inclusion. The case studies included for discussion are a low rise, high rise and underground services contract located in Ireland, Northern Ireland and USA respectively. Each case study is selected after being shortlisted from a total of 12 possible case studies and is chosen due to the availability of individuals to participate in the research, the internal varying intricacies on-site, the scale of the project in question and the overall complexities associated with each, due to the confined nature of the projects in question. Specific emphasis is then placed on productivity within the construction sector while also reviewing the construction sector as a whole. Thirdly, with regards to the qualitative data collection, a number of construction sector companies within each case study are approached and requested to participate in the research through individual interviews and also focus group seminars. Based on the numerous factors in the literature, analysis of three industry specific and diverse case studies, examination of individual

interviews and also focus group seminars, a plethora of factors are identified for further qualitative analysis and discussion.

ANALYSIS

From the exhaustive list of factors identified, a process of factor examination through the use of mind mapping and causal loop assessment is undertaken (Figure 1). By reviewing the results of the qualitative analysis by means of confirmatory discussions, it is then possible to identify the leading impacting factors of personnel productivity in a confined construction site environment. Table 1 documents the 15 factors identified in relation to the case studies chosen, tabulated in order of preference as prescribed by the interviewees questioned.

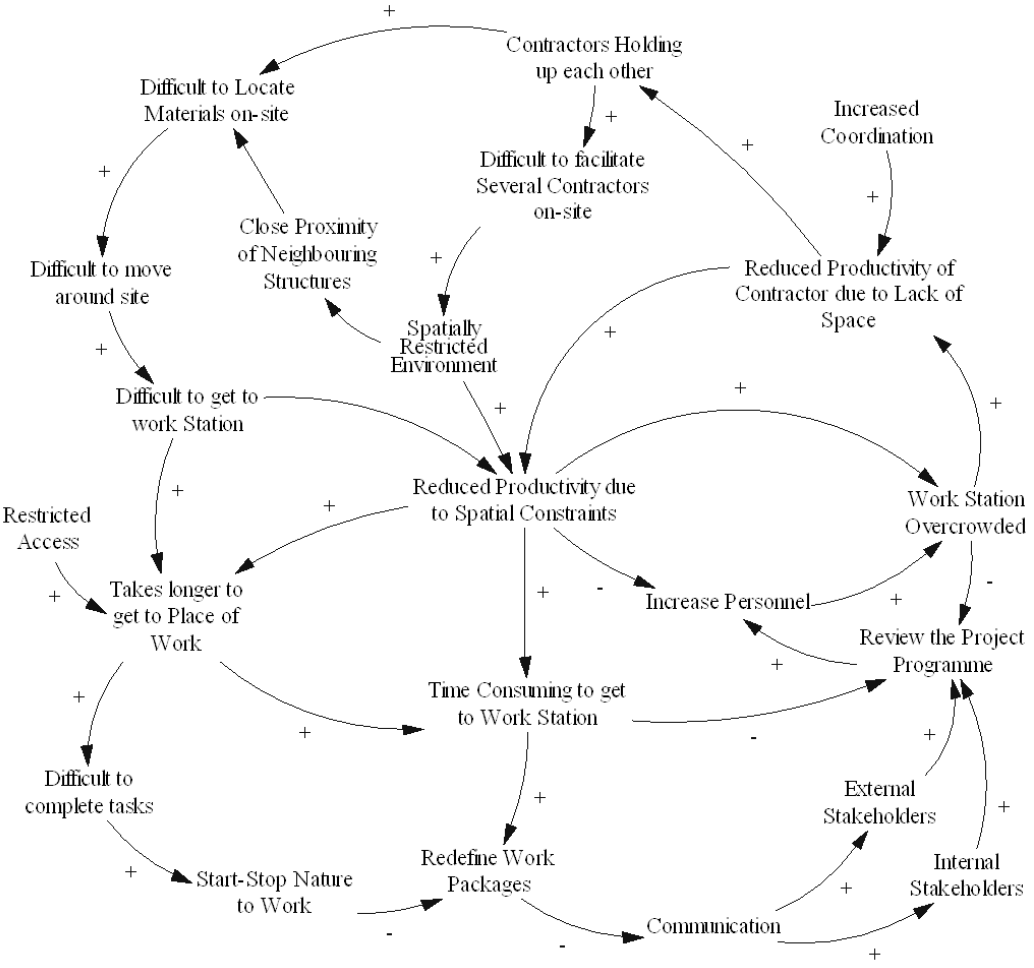

Figure 1: Causal loop of factors impacting personnel productivity

Factor	Case Study 1	Case Study 2	Case Study 3
Overcrowding of personnel at workstations	X	X	X
Lack of space for the effective movement of personnel	X	X	X
Numerous trades working within the one space	X	X	X
Difficult to transport material because of the lack of space	X	X	
One contractor holding up another due to the lack of space	X	X	X
A risk to personnel because of vehicular traffic on-site	X		X
Difficult to facilitate several contractors at one work location	X	X	X

Reduced personnel output due to inadequate space		X	X
Difficult to complete tasks due to the spatial restrictions	X	X	X
Concern of the close proximity of neighbouring structures	X	X	
Start-stop nature to activities due to overcrowding		X	X
Difficult to get to / from the work place	X	X	X
Difficult to co-ordinate personnel in the assigned spaces		X	
Poor project programming resulting in overcrowding	X	X	X
Restricted access at work stations to complete work tasks	X	X	X

Table 1: List of factors identified and corresponding case studies

DISCUSSION

The most prominent factors identified are listed accordingly, based on cluster, hiset and domain analysis of the extracted datasets using mind mapping software. Each of these factors are core to each of the discussions and resulting individual case studies documented and reviewed and thus, are prevalent within a confined site environment, regardless of being a low rise, high rise or underground development.

Overcrowding of personnel at workstations

From the qualitative analysis and the case study examination, the leading factor identified by all and which resonates throughout each case study, interview and focus group is the issue of personnel overcrowding at workstations. Thomas and Riley, (2006) compound the severity of the issue by documenting that congestion in the workplace is detrimental to labour productivity and thus, must be avoided at all costs. In addition, Mokobane, (2006) furthers this point by indicating that productivity is adversely affected due to the increased health and safety concerns which result in reduced productivity within such environments. Where the possibility of overcrowding at workstations is realised, on-site management must take all possible actions to mitigate or eliminate the adverse effects of such an environment, in order to ensure that productivity of personnel is not adversely affected.

Lack of space for the effective movement of personnel

The second factor identified is the lack of space which results in impairing the effective movement of personnel in and around site. Again, as before, the leading trait identifiable is the lack of space and the resulting adverse effect on personnel productivity on-site. Thomas and Riley (2006) also identify difficulties in the movement of personnel on-site as one of the leading issues in relation to productivity with Ning, *et al.,* (2011) also highlighting the difficulties with multiple trips by personnel on-site. Therefore, the negative impact of this factor on personnel productivity is firmly rooted and must be acknowledged, thus enabling on-site management to proactively manage the limited space, with the aim of ensuring the effective movement of personnel on-site, thus improving the overall productivity.

Numerous trades working within the one space

The third and final factor for discussion is again noted in all three of the case studies and encompasses stacking of trades on-site and particularly within one location on-site. McDonald and Zack, (2007) argue that this practice has a detrimental effect on productivity on-site. In addition, they highlight that each trade should have sufficient space within their work environment to ensure that they can perform their tasks sufficiently while not being interfered by either oncoming or trailing trades. Furthermore, they conclude that the practice of schedule acceleration can also have a

negative effect on trade stacking, but this factor is exasperated in confined site environments, where spatial restrictions are evident throughout.

CONCLUSION

With the continued development and expansion of urban centres (Heimlich and Anderson, 2001), the need for redevelopment has continued at pace. One of the negative aspects of developing within this environment is the spatial deficiency which persists in the vast majority of inner city sites. This can result in a number of issues, one of which is the negative effect on labour productivity on-site. As documented, by adopting a qualitative approach in the form of a critique of the literature along with mixed method case study analysis individual interviews and focus groups, 15 factors are identified which negatively contribute to a reduction in personnel productivity on inner city, confined construction sites. The subsequent leading negative impacting factors are 1) overcrowding of personnel at workstations, 2) lack of space for the effective movement of personnel, and 3) numerous trades working within the one space. Where on-site management professionals are faced with ensure project success in such a spatially restricted environment, the findings presented are of particular interest and benefit. By acknowledging and counteracting the factors identified, it is possible to mitigate the negative impact of reduced labour productivity, thus increasing the possibility of ensuring project completion and thus, project success.

DIVERSIFICATION AND PERFORMANCE OF QUANTITY SURVEYORS IN NIGERIAN CONSTRUCTION INDUSTRY

Bashir O. Ganiyu[1], Luqman O. Oyewobi,[1] Lynda Nwokobia,[1] and Bolaji Sulaiman[1]
[1]*Department of Quantity Surveying, Federal University of Technology, P.M.B. 65, Minna - Nigeria.*

ABSTRACT

Quantity surveying profession is fast becoming a dynamic profession due to the rate at which professional Quantity Surveyors diversify into other business endeavors. In recent times, it was discovered that Quantity Surveyors are diversifying from their traditional roles due to expansion of knowledge and the rapid high cost of living facing the present economy. This research was conducted for the purpose of finding out the effects the diversification has on the performance of Quantity Surveyors in the Nigerian Construction Industry. The study outlined the traditional roles of the Quantity Surveyor, identified the various factors that cause a Quantity Surveyor to diversify from his traditional roles and the areas which the Quantity Surveyor diversifies into. The results of the survey showed that diversification have both positive and negative effects on the performance of Quantity Surveyors.

Keywords: Construction industry, Diversification, Performance, Traditional-role.

INTRODUCTION

Construction professionals in contemporary business organizations are faced with problems of Business survival over the past decades, under the premise that growth is a vital element for business survival, a firm can grow and develop its core competencies either internally by investing in and nurturing within-firm resources or externally through diversification into other areas of businesses.

Change is occurring in the world today and the pace seems to be accelerating faster than ever. Change management has, in recent years, become a very important aspect in the study of organizational behavior and same applies to practice of professional quantity surveyors.

[1] Bashalaanu74@gmail.com, bashiroganiyu@futminna.edu.ng

Quantity Surveyor (QS) is a professional working within the construction industry concerned with building costs. It is a profession that provides a qualification gained following formal education, specific training and experience that provide a general set of skills that are then applied to a diverse variety of problems. Predominantly these relate to costs and contracts on construction projects.

Nigerian Institute of Quantity Surveyors (2004) defined a quantity surveyor as the expert professionally trained and experienced in dealing with construction cost, construction management and construction communication. Studies of Ashworth and Hogg (2002) describe the Quantity Surveyor as the one who 'ensures that the resources of the construction industry are utilised to the best advantages of society by providing, inter alia, the financing management for projects and cost consultancy services to the client and designer during the whole construction process.'

Olusoga (2006) observed that Nigerian quantity surveyors of older generation were more of experts in the costing, cost monitoring and control as it relates to building projects which they were respected for by their sisters' professionals.

Although it is true that today's quantity surveyors want to expand the horizon of their practice as observed by Seppanen (2002). However, most of the expansion by practising Quantity Surveyors in Nigeria as the case may be is into costing of engineering projects which is still within the traditional role of the older generation of quantity surveyors especially in the developed world.

Jagun (2006) opined that the quantity surveying profession is faced with great challenges in Nigeria. Steven (1990) observed that quantity surveying is becoming an increasingly influenced occupation while Sigle, Klopper and Visser (2000) believed that these clients are increasingly demanding application of value management to their projects.

The quantity surveying profession is imperative in construction industry and the role of the quantity surveyor is characterised in several ways. However, Concerns in the coming decade will be dominated by the need to anticipate and satisfy changing client requirements amidst other demands for better standard of living by construction professionals in Nigeria (Aje & Awodele 2006). This called for a need to examine the present performance of Nigerian quantity surveyors in their quest for better service delivery viz a viz their involvement in other forms of businesses outside their core professional role. The research problem then lies in examining whether Diversification affects the performance of Quantity Surveyors in the discharge of their professional responsibilities.

Who is a Quantity Surveyor

The quantity surveyor (QS) is a professional working within the construction industry concerned with building costs. Though limited to building, the definition added that the profession provides qualification gained through formal education, specific training and

 ISBN: 978-1-84219-840-7 .

experience that provide a general set of skills that are applied to a diverse variety of problems which relate to costs and contracts on construction projects.

The Nigerian Institute of Quantity Surveyors gives a more compact and definite definition of the QS as the professional responsible for total cost and procurement management and concerned with financial probity and value for- money in the conceptualization, planning and execution of development projects in the building and construction sector of the economy.

Quantity surveyors are called by so many names all over the world such as cost engineers, building economists, cost managers, construction accountants, and different authors have adopted these different names in different studies (Seeley and Winfield, 1999; Kelly and Male, 2006) and in Nigeria, (Ajanlekoko, 2004; NIQS, 2004; Babalola, 2006; Odeyinka, Oladapo & Akindele 2006;).

Competent quantity surveyors must have a range of skills, knowledge and understanding which can be applied in a range of contexts (Hassall, Dunlop & Lewis, 1996).

The Role of a Quantity Surveyor

The role of the Quantity Surveyor has changed over the years and the present Quantity Surveyor exhibits their competencies in diversified paths within the construction industry as well as beyond the boundaries of the construction industry. Among the evolved and developing paths of the profession, finance is a lucrative industry providing a broad scope of opportunities for Quantity Surveyor to undertake careers in insurance and various finance positions in banks or as corporate finance entities.

Quantity Surveyor usually reports to Project Manager or Project Director and provides advice in the decision-making process throughout the management of a project from initial inception to final completion. The Quantity Surveyor handles estimating and cost control, the tendering process and, after contract award, the commercial interface.

Quantity Surveyors should be able to carry out estimating and measurement of construction works prior to tender, producing the bill of quantities; produce tender documentation and manage the tender process; clarify and evaluate tenders; and manage the resultant contract through monthly valuations, variations control, contract administration and assessment of claims.

Some Quantity Surveyors are trained in techniques of cost control. Others emphasise contracts management.

Some Quantity Surveyors specialise in project management and running multi-disciplinary projects, the Quantity Surveyor background being a good foundation for understanding the complexities of modern large-scale projects.

Factors Leading to Diversification by Quantity Surveyors

The last decade of the 20th century and indeed the past 20 years witnessed significant changes in the construction industry in the UK particularly following the global recession

of 1990-1995 (Cartlidge, 2006; Ashworth & Hogg, 2002) which took its turn on Nigeria. The reasons for these changes include; Expanding scope and scale of construction projects due to massive industrialization and globalization, Emergence of new markets for construction products which led to reduction in public sector spending with massive increase in large private Sector led investments, Changes due to client-led demand since the traditional practices centered on quantities were considered a low-cost activity, Contractor-led changes due to emergence of large firms with diverse knowledge and capabilities.

Some other reasons for the changes in the construction industry as identified by Harun and Abdullahi, (2002) is expansion of knowledge and learning. It should be noted here that financial skills of Quantity Surveyors is now subservient to knowledge, innovation, entrepreneurship and creativity, particularly in business and commerce (Drucker, 1993). Also, the Information Technology Revolution, Globalization and World Economic Growth, Increased Clients' Expectations (Moore, 1984; Bates, 1986; Cattell, 1994). Smith (2010) highlighted; Fee cutting and bidding among Firms. Firms clearly recognize the fact that project cost management is not the exclusive domain of the quantity surveying profession.

Some quarters are dissatisfied with the quality of graduates from university courses particularly in terms of core skills in measurement and construction knowledge. Some firms have found that graduates are not interested in the technical measurement role.

Effects of Diversification

Corporate diversification has the potential to either enhance or destroy value and performance of a firm from discharging its core professional responsibilities. Regarding the value-enhancing aspects of diversification, Lewellen (1971) argues that diversified firms have greater debt capacity than do single-segment firms, which implies a larger debt tax shield and higher firm value. Chandler (1977) opined that diversification may lead to operating efficiency by enhancing economies of scope and increasing managerial coordination.

On the other hand, diversification may lead to value destruction, which is ultimately attributable to information asymmetries. First, the benefits of diversification described by Chandler (1977) may be offset by costs associated with increased information asymmetry between headquarters and individual divisions (Harris, Kriebel, & Raviv 1982). Second, in the presence of asymmetric information the potential for residual agency problems between management and shareholders exists. For instance, rather than using internal capital markets as a means of solving the underinvestment problem, Denis, Denis, and Sarin (1997) document negative association between the level of diversification and the equity ownership of executives as well as the presence of large blockholders; however, they find no evidence to support the notion that ownership structure is associated with the diversification discount once the decision to diversify has been made.

Quantity Surveyors have really taken on the challenge of diversification to better meet and serve industry demands. This indicates, in part at least, a proactive approach to change by many firms. They also demonstrate the very broad range of employment and business opportunities available for the modern day quantity surveyor. The involvement of Quantity surveyor in other professional disciplines further demonstrates the overlapping nature of the profession and the increasing need for quantity surveying professionals to work as part of multi-disciplinary teams on projects.

Due to rapid changes and diversification in both the profession and the construction industry, it has become more important to produce well qualified and competent graduates to meet the challenges and the increasing demand of the profession.

Diversification is one of the strategies for reducing firm risk or seeking growth opportunities to sustain the firm's life. As a result of diversification, Quantity Surveyors are not only deviating from their traditional roles but also looking for new ways to broaden their knowledge in the already existing traditional roles. Some of them are briefly explained below.

RESEARCH METHODOLOGY

The study focused on professional Quantity Surveyors, practicing in Nigeria. The primary data were collected directly from the field through the use of structured questionnaires, field observation and oral interview to professional quantity surveyors. The questionnaires were structured and administered in Abuja during the International Conference organized by The Nigerian Institute of Quantity Surveyors (NIQS) and Quantity Surveyors Registration Board of Nigeria (QSRBN) Round Table & Assembly. These enhance easy distribution of the questionnaires and enhance genuine responses from the respondents. A total of 120 questionnaires were administered out of which 91 was returned and subsequently used for analysis. Simple percentile was used to analyse the respondent background information, Factor analysis was used to reduce the variables and severity index of the factors was then determined and used to rank the variables according to their degree of importance.

RESULTS AND DISCUSSION

Table 1. reveals that 12% are professionally qualified/registered to practice quantity surveying, 6% are Fellow of NIQS (FNIQS), 42% are Corporate members of NIQS (MNIQS), 40% are probationer members of the NIQS. The table shows that all respondents are professional Quantity Surveyor. This gave the assurance that the responses could be relied upon.

Table 1: Professional Qualification

Professional Qualification	Frequency	Percentage %

 ISBN: 978-1-84219-840-7 .

RQS	6	12
FNIQS	3	6
MNIQS	42	42
Probationer NIQS	40	40
Total	91	100

The results of severity index of negative effects diversification has on the performance of quantity surveyors in the Nigerian construction industry, ineffective Quantity Surveying practice was first with severity index of 62%, followed by lack of competitive edge in the Quantity Surveying practice, 56% for general decline of the Quantity Surveying practice, 55% for Inefficiency in assigned traditional Quantity Surveying duties while Delay in completing tasks has 54%.

Table 2: Negative effects diversification has on the performance of Quantity Surveyors in the Nigerian Construction Industry

NEGATIVE EFFECTS	SEVERITY INDEX %	RANK
Ineffective QS practice	62	1
General decline of the QS practice	56	3
Lack of competitive edge in the QS practice	58	2
Inefficiency in assigned traditional QS duties	55	4
Delay in completing tasks	54	5

Table 3: Positive effects diversification has on the performance of quantity surveyors in the Nigerian Construction Industry

POSITIVE EFFECTS	SEVERITY INDEX %	RANK
Education	42	4
Research producing new and improved methods	47	2

Increased awareness of Quantity Surveyors	43	3
Quantity Surveyors involved in politics formulating policies in favour of the profession	61	4

Positive effects diversification on performance of quantity surveyors in the Nigerian construction industries is shown on Table 3. Politics formulating policies in favour of the profession was ranked first with severity index of 61%, and increased awareness of Quantity Surveyors has 43%, while Education has the least severity index of 42%.

CONCLUSION

A quantity surveyor is referred to as 'Jack of all trades and master of all'. This simply means he has broad knowledge about alot of activities in the construction industry and will easily fit in and deliver on any task given to him.

Based on the findings, from the results of analysis, the study showed that quantity surveyors do not fully concentrate on their traditional roles but instead are looking for quick ways to get more money by diversifying into other areas for personal interest, gaining more knowledge, to meet up with the high cost of living and increased customer expectation.

Diversification affects the quantity surveying practice positively because it further widens the knowledge base of the professionals and produces better quantity surveyors. It also affects the profession negatively, these is evident from the level at which QS abandon their traditional roles and take up other duties which may not be related to the quantity surveying profession or the construction industry as a whole.

IMPROVING PROFESSIONALISM IN CONSTRUCTION CUSTOMER SATISFACTION: THE PINNACLE APPROACH

James Somerville[1], Nigel Craig[1] and Nicola Callaghan[1]

[1]*School of Engineering and Built Environment, Glasgow Caledonian University, G4 0BA, United Kingdom.*

ABSTRACT

The measurement of customer satisfaction forms an integral part of improving construction operations and enhancing customer experiences, so creating competitive advantage and increasing revenue. At the heart of the customer experience lies their overall satisfaction, which is fundamentally linked to organisational strategies and exhibited professionalism. Contemporaneous evidence suggests a lack of any "standard" service quality model used by all construction professionals to monitor customer satisfaction and yet, construction professionals need to measure customer satisfaction using an "appropriate and atypical" technique. A factor analysis meta-model is proposed that integrates a number of approaches to customer satisfaction management and drives towards a "Pinnacle Approach": linking the predominant influences of building and service quality; organisational; and, human factors. Weightings attaching to each of the influence factors, within the customer satisfaction and factor analysis meta-model, aid in identifying the predominant influences on customer satisfaction and enable construction professionals to prioritise areas for improvement. The model also allows exploration of previously unconsidered factors, thus ensuring professional fluidity at every level. As organisational practices come closer to the peak of the triangle, so professionalism will increase creating positive customer satisfaction and business benefits.

Keywords: Construction, Customer Satisfaction, Service Quality.

INTRODUCTION

Customers are valuable assets for organisations, but are often costly to acquire and retain (Jakštien *et al.,* 2008). In recent years, the construction industry has had the difficult task of encouraging new buyers to purchase homes in the midst of failing markets, low consumer confidence and potential credit difficulties. As pressures increase and home buyers become better informed; proactive construction organisations are realising the need to redesign and redevelop their business strategy to practice good customer relations (Forsythe, 2007). In an attempt to alleviate such issues, service quality and customer satisfaction benchmarks are becoming important means of gaining a competitive advantage within the marketplace and increasing

[1] nicola.callaghan@gcu.ac.uk

profit. As a result, house builders need to identify and understand buyer needs in order to continuously improve their service level. The majority of studies focus on build satisfaction related to the construction process, including that of defects at handover. However, very few have combined both build quality and customer experience in a single conceptual review. As such, this research paper aims to produce a factor analysis meta-model encapsulating a variety of individual service quality models and combining them to create a single point of reference for all construction professionals. In addition, the relationship between build experience and customer experience will be assessed and related to overall professionalism. Throughout the research the "customer" can be defined as anyone who procures goods or services from an entity, including the client and all other construction professionals.

CUSTOMER SATISFACTION

Customer satisfaction has become an important business driver and managerial focus in many professional areas, including construction (Kotler, 2000), where customer satisfaction is regarded as an aspect of quality (Yasamis *et al*., 2002) and an important indicator of project success (Delgado-Hernandez and Aspinwall, 2005). Managing customer satisfaction is therefore at the forefront of many business agendas with an increasing tendency towards customer orientation, in an attempt to create continuous improvement whilst gaining benefits of improved communication, increased customer loyally, increased referral rates and superior economic returns. As the cost of retaining an existing customer is less expensive than seeking new ones, understanding customer purchase intentions is a vital means of forecasting purchasing behaviour (Spreng *et al.,* 1996). Current research suggests that purchase intentions increase as service recovery increases. Similarly, poor service delivery is likely to hinder future purchase intentions. According to Himansu (2009) there are four major factors which influence the purchase intentions of the customers: Psychological Factors, Social Psychological Factors, Sociological Factors, and Economic Factors.

SERVICE QUALITY

Over the years, the term "service quality" has been widely discussed by various researchers such as Parasuraman *et al.,* (1985), Haywood-Farmer (1988) and Sweeney *et al.,* (1997). An interesting study undertaken by Seth *et al.,* (2005) reviewed and appraised some of the most popular service quality models. Although the research discussed all of the major observations of each of the models, all were looked upon in isolation. Similarly, evidence suggests a lack of any "standard" service quality model used by all construction professionals to monitor customer satisfaction and yet, construction professionals need to measure customer satisfaction using an "appropriate and atypical" technique. Figure 1 shows a single factor analysis "meta-model" encompassing all of the factors which should be considered when assessing the level of service that a customer has received. The model has been created by linking 10 of the most popular service quality models, dating from 1984-2000. Although several service quality models have been developed since 2000, the majority of these are based on the "original" models which remain the most widely recognised and commonly used models to date.

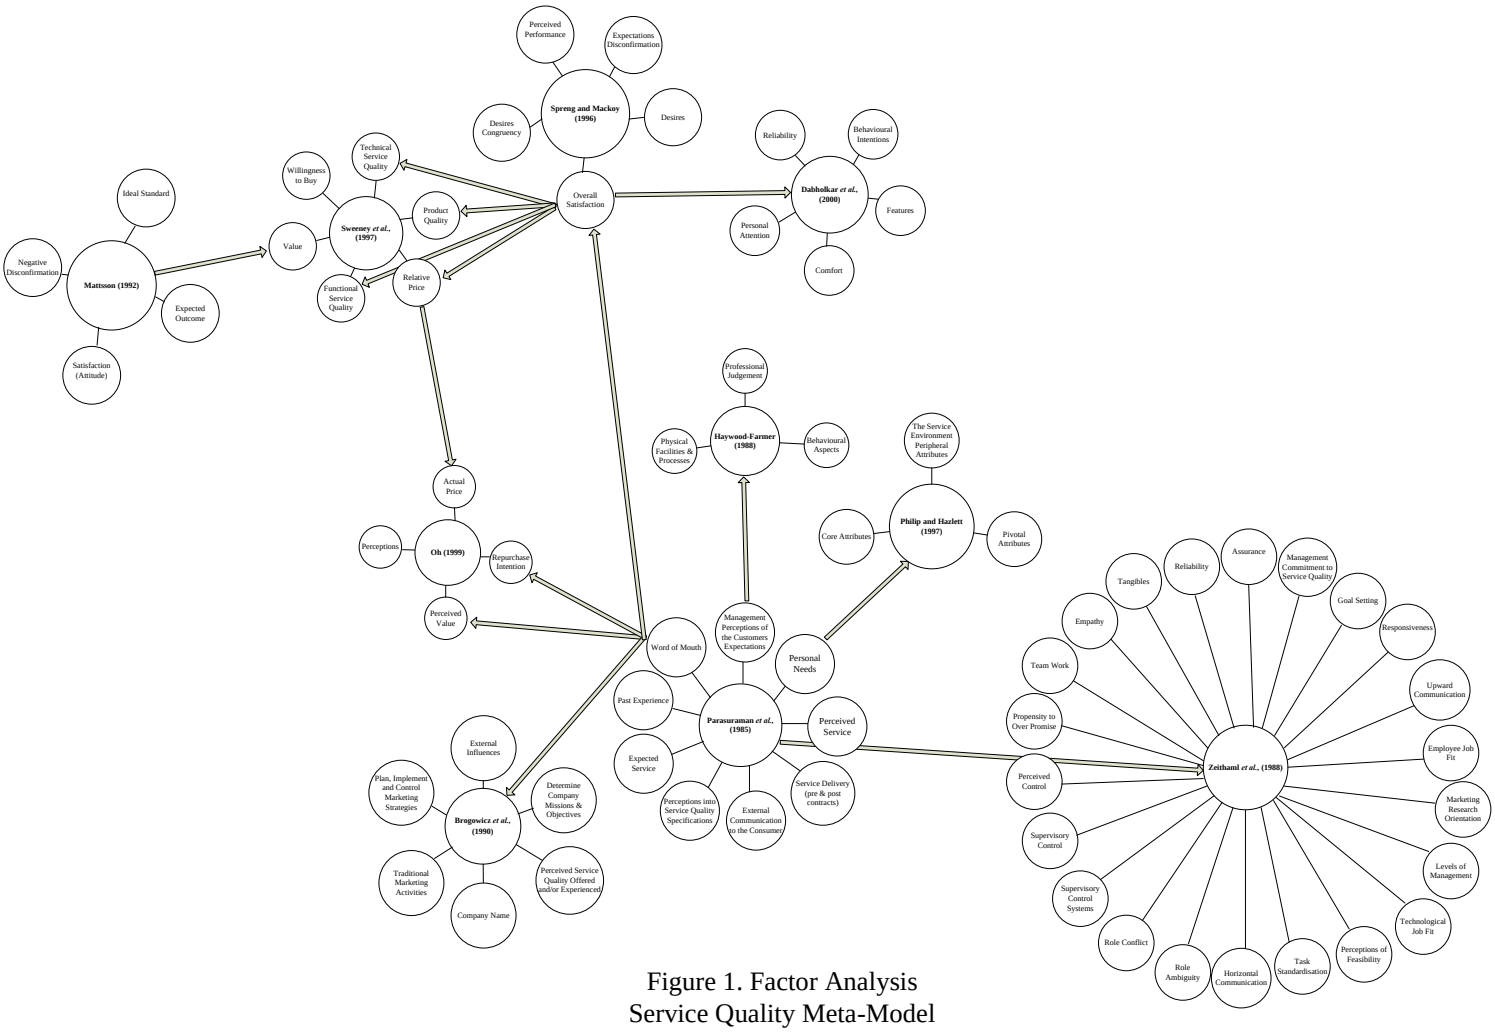

Figure 1. Factor Analysis
Service Quality Meta-Model

THE "PINNACLE" OF SATISFACTION DRIVING PROFESSIONALISM

The idea of "professionalism" relates to overall customer satisfaction and the service provided by professionals. In order to obtain "professionalism" accreditation, all construction professionals – including designers, architects, engineers and house builders need to understand the influence of customer satisfaction and the potential consequences of their actions on the business model. This includes "learning from their projects, forging better links between practice and research and embedding knowledge in their organisations and the wider industry" (Bordass, 2011). Similarly, organisations should "take account of outcomes during briefing, design and construction" (Bordass, 2011) and use such information to provide a superior build experience for the customer in terms of the time, cost, quality and safety of the build. Finally, organisations should also consider overall customer experience in terms of expectations, needs, wants and desires related to the service delivered. =

Build and Customer Experience

Traditionally, construction is not a customer orientated industry (Dulaimi, 2005). As a result, evidence suggests that the perceived build quality e.g. in new housing, is lower than customers would expect, often resulting in high levels of dissatisfaction (The Housing Forum, 2000, cited by Auchterlounie and Hinks, 2001). In order to increase

customer satisfaction, project managers should; have a clear understanding of the clients brief, ensure positive contractor involvement, select the most appropriate design team, encourage accurate reporting, ensure supervision and control during construction and implement effective evaluation and feedback methods. As a result, it is vital that managers achieve the right balance of time, cost, quality and safety in order to build lasting relationships, increase satisfaction and secure repeat business. According to Johnston and Kong (2011), customers will have an "experience", every time they encounter a service, whether it is good, bad or indifferent. A customers experience is inherently unique and will differ from individual to individual, with varying interpretation of the service received (Pine and Gilmore, 1998). The overall customer experience will influence future behaviour associated with purchases, recommendations or complains, which are all likely to effect an organisations reputation, bottom line and competitive advantage.

Customer Perceptions and Expectations

There are numerous factors which may influence the purchase decisions of potential buyers including perceived risk, price perception, customer's income and need stratification. Researchers, such as Sirgy (1982) believe that customers choose products which are consistent with their perceptions; however, as individuals perceive situations and interpret information differently, customer behaviour is often difficult to predict (Drew and Bronkhorst, 1996). The more experience the customer gains or more knowledgeable they become, the more likely that their perceptions will change, resulting in an increased focus on the service consumption.

Similarly, expectations play a pivotal role in most modern day discussions surrounding service quality (Coye, 2004). Very often customer expectations relate to how well the service encounter has met overall expectations in terms of being "true or false, good or bad and desirable or undesirable" (Clow *et al.,* 1997). Similarly, expectations may also be "fuzzy or focused, implicit or explicit, unrealistic or realistic" (Ojasalo, 2001). However, many customers are willing to accept a degree of flexibility known as the "zone of tolerance" (ZOT) (Zeithaml and Bitner, 2000) which highlights the difference between what is "desired" and what is considered "adequate" service (Dean, 2004). The wider the ZOT the more accepting customers are of variations in the level of service received.

Needs, Wants and Desires

Gaining a clear understanding of what customers need, want and desire is one of the most effective ways of creating a positive customer experience (Max-Neef, 1992). In most cases, the client will need the building to be; functional, safe, and economical whilst complying with to building regulations and other standards. Wants within the context of construction, however, often refer to the overall aesthetics and design of the building including communications systems, building materials or the interior furnishings. Desires, on the other hand, are more negotiable and refer to the things that the client hopes for. Very often the delivered service quality differs somewhat from the expected service (Taylor and Miyazaki, 1995). As a result, many researchers have highlighted the need to distinguish between customer's expectations (i.e. the needs, wants, and desires) and delivered performance.

THE PINNACLE APPROACH

As a way of assessing and interpreting customer satisfaction, the "Pinnacle Approach" aims to monitor customer satisfaction and address organisational professionalism. The proposed model (shown in figure 2) has been created to become the standard model used by all construction professionals, which accounts for both build and customer experience in order to provide a holistic representation of the actual experience received. The triangle has an existing baseline, which is joined to two sides, one labelled "management"; relating to the organisations management of time, cost, quality and safety, and the other labelled "customer"; relating to the customers expectations and the delivered service based on needs, wants and desires. Both axes close at the top to form a "satisfaction peak".

Methodology

The following equation has been developed by reviewing previous service quality models. The level of satisfaction relating to customer experience is determined by weightings attaching to needs, wants and desires and whether or not the expectations were fully met (100%), partially met (50%) or not met (0%). A theoretical example of customer weightings is shown in table 1. As each customer is unique, the weightings will change to reflect the overall level of importance. However, in this example it is suggested that the "customer" felt that their needs were most important to them (50%), followed by their wants (30%) and their desires (20%).

$$\text{Customer Experience} = \sum Nw\,(NPF) + Ww\,(NPF) + Dw\,(NPF)$$

$$= \sum N0.5\,(1) + W0.3\,(1) + D0.2\,(0) = 0.80\,(80\%)$$

Table 1. Customer Experience Weighting

Customer Weightings		Customer Experience		
		Not Met (0%)	Partially Met (50%)	Fully Met (100%)
Needs	50%	N	P	F ✓
Wants	30%	N	P	F ✓
Desires	20%	N ✓	P	F

* Nw = Needs Weighting Ww = Wants Weighting Dw= Desires Weighting

Similarly, the level of satisfaction delivered relating to the management of the build is determined by weightings attaching to time, cost, quality and safety.

Historical information shows, that in the majority of cases, the build and customer experience will not be equal. As a result, as the baseline moves upwards to join the dots plotted on the axes, the triangle becomes skewed. Shown in figure 2, is an example of a 65% build experience and 80% customer experience. However, should an organisation consistently receive 90% or above for both build and customer

experience, they are deemed to fall within the "golden triangle" as the result of very satisfied customers. "Peak satisfaction", on the other hand, occurs when 100% build and customer experience is achieved. Although such results seem unlikely the peak serves as a striving point for all organisations who aim for "peak satisfaction" and indeed professionalism at every level. The better the overall experience the smaller the triangle becomes and as organisational practices come closer to the "pinnacle", so professionalism will increase creating positive customer satisfaction and business benefit.

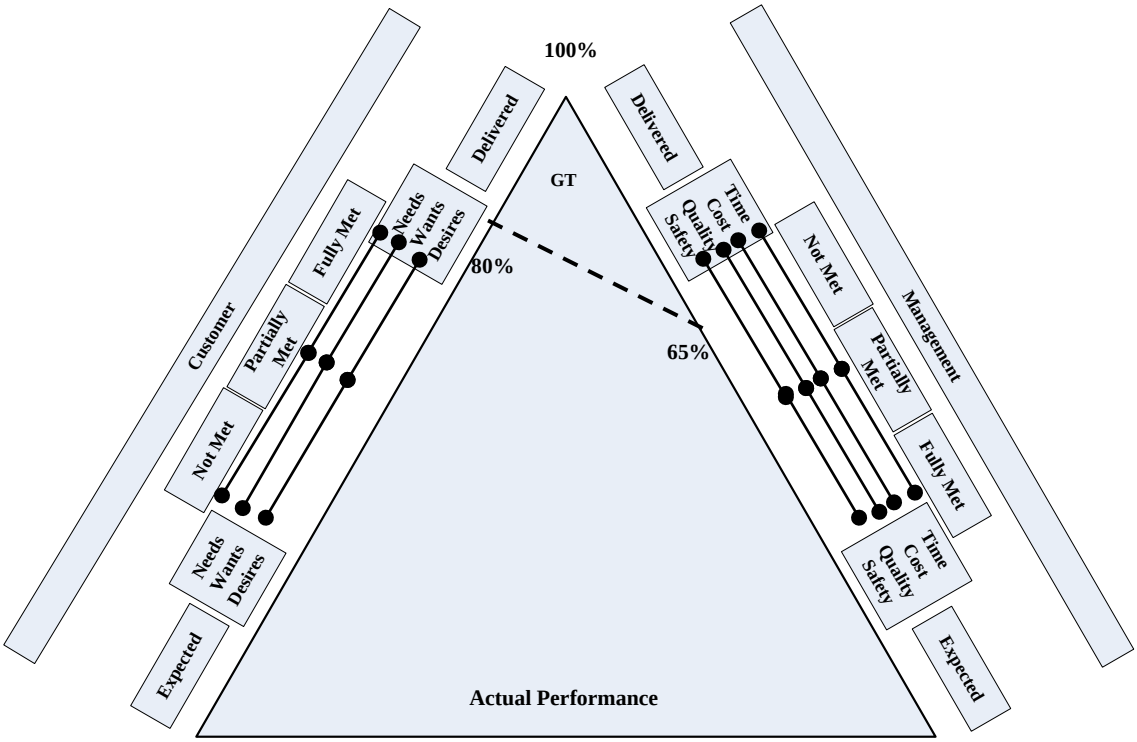

Figure 2. Skewed Pinnacle Approach Triangle

* Customers may assess their overall level of satisfaction by considering the following factors: external influences, perceived service quality offered and/or received, personal needs, past experiences, expected service, perceived service, perceived value, repurchase intention, relative price, value, willingness to buy, ideal standard, expected outcome, negative disconfirmation, satisfaction (attitude), behavioural intentions, perceptions, perceived performance, desires, desires congruency, expectations disconfirmation and overall satisfaction.

* Management may assess the organisations overall performance by considering the following factors: tangibles, reliability, responsiveness, assurance, empathy, team work, employee job fit, technological job fit, perceived control, supervisory control, supervisory control systems, role conflict, role ambiguity, external communications to the consumer, horizontal communication, prosperity to over promise, task standardisation, goal setting, perceptions of feasibility, management commitment to service quality, professional judgement, physical facilities and processes, behavioural aspects, features, comfort, personal attention, reliability, functional service quality, technical service quality, product quality, actual price, marketing research orientation, upward communication, levels of management, word of mouth, company name, marketing strategies, traditional marketing activities, core attributes,

pivotal attributes, translations of perceptions into service quality specifications, management perceptions of the customer's expectations, service delivery (including pre & post contracts) and the service environment peripheral attributes.

CONCLUSIONS

The findings of the research confirm that customer satisfaction forms an integral part of improving business operations and enhancing customer experiences whist creating competitive advantage, increasing revenue and ensuring long term business relations. Although a wide range of models exist which assess customer satisfaction and service quality, this paper has presented two unique models designed for construction use. The factor analysis meta-model has been created which can be used by all construction professionals to monitor customer satisfaction using an "appropriate and atypical" technique. The model can be used to identify the important influences on customer satisfaction, allow organisations to quickly and easily identify areas of weakness and management professionals to prioritise areas for improvement. Additionally, the research describes the use of a "pinnacle approach" by linking the predominant influences of building and service quality in respect to customer satisfaction. As organisational practices come closer to the peak of the triangle, so professionalism will increase creating positive customer satisfaction and business benefit. Although the "pinnacle approach" has been specifically developed for use within the construction industry, the concept is transferable to other industries which aim to monitor and improve customer service and satisfaction. Overall, the paper concludes that both the factor analysis meta-model and "pinnacle approach", when correctly applied, have the potential to add value to the customer satisfaction approaches utilised within the construction industry.

INSTITUTIONAL BARRIERS IMPEDING PARTNERING IN BELGIAN PUBLIC CONSTRUCTION PROJECTS

Nele M. Boussemaere MSc [1]

Department of Architecture, Real Estate and Housing Delft University of Technology, PO box 5, 2600 AA Delft, NL
Department of Architecture, Construction management LUCA Ghent-Brussels, Hoogstraat 51, 9000 Ghent, BE

ABSTRACT

The traditional organising method of design, bid, build is proven to be unsuitable to deliver through-life value in construction projects. Implementing through-life value teams, establishing partnering structures which connect business need, design, production, handover and use of a new facility, are increasingly encouraged worldwide. Many researchers reported on measureable successes and some questioned the low level of adoption.
The move to integrated project teams being witnessed elsewhere is not taking place on the same scale in Belgium. Relative to other countries Belgium is not going down this 'partnering' path, although there is clear evidence of growing dissatisfaction and inefficiencies in outcomes in the Belgian construction industry, especially in public construction projects.
Why are partnering or integrated project teams not widely prevalent worldwide? The aspects preventing the adoption of partnering are categorised in cultural barriers, regarding people and their attitude, organisational barriers concerning processes and routines and institutional/industrial barriers. For Belgian construction actors the latter is regarded as critical, because legislation and regulations support, strengthen and, form the cultural and organisational barriers.

Keywords: barriers, Belgium, institutional, partnering, public.

INTRODUCTION

The myriad pressure of drivers as globalisation, international project teams, international client systems, demand for greater efficiency is, in part, bringing about a shift towards through-life value. As the traditional organising method of design, bid, build, with a focus on price and competition offer little incentive for trust and cooperation to emerge (Cheung et al., 2003), this method is proven to be unsuitable to deliver this through-life value in construction projects. Implementing integrated through-life value teams, establishing partnering relationships in which all project actors collaborate to connect business need, design, production, handover and use of a new facility, are increasingly encouraged worldwide. This trend is apparent in countries like the UK (Naoum, 2003), Japan (Chan et al., 2006) and Sweden (Eriksson et al., 2008, 2009) where researchers reported on measureable successes.

[1] n.m.boussemaere@tudelft.nl

The move to integrated project teams being witnessed elsewhere is not taking place on the same scale in Belgium. Relative to other countries Belgium is not going down this 'partnering' path. Therefore the espoused benefits of integrated, collaborative working are not being experienced. Although there is clear evidence of growing dissatisfaction and inefficiencies in outcomes in the Belgian construction industry, construction participants as well in public and private sectors do not seem to look for alternatives.

Without this move towards proper integration of design, construction and operation functions requiring a move to fully integrated project teams, early supply team involvement, continuous improvement processes, joint commitment and sharing risks, responsibilities and profits best through-life value will never be achieved. Adversarial relationships and disputes will continue to dominate the industry. No mutual trust and commitment will get established.

Although partnering seems to be a suitable alternative to traditional procurement, to achieve through-life value, its low level of adoption should be questioned. Why are partnering or integrated project teams not widely prevalent worldwide? Based on several other researches, Eriksson et al. (2008, 2009) detected three types of barriers preventing the adoption of partnering in the construction industry.

BARRIERS TO PARTNERING

The aspects preventing the adoption of partnering are categorised in cultural barriers, organisational barriers and institutional or industrial barriers.

Cultural aspects regarding people and their attitudes, like conservatism, inflexibility, low commitment, mistrust often constitute a vital barrier to change (Ng et al., 2002), as well as the adversarial culture in the construction sector (Bresnen and Marshall, 2000) with parties trying to achieve individual objectives, rather than working together towards mutual objectives.

The second group of barriers involve organisational aspects. The traditional organisation of construction projects in which distinct packages are allocated individually to different specialists together with the client's competitive tendering habits, hampers the integration of work tasks and actors (Briscoe et al., 2004). These factors are even strengthened through legislation (see next section). Ng et al. (2002) report that relationships become strained if actors have low confidence in each others' competences. Every party involved needs to develop new competences to participate in partnering projects (Eriksson et al., 2008). Exchanging competences among participants in collaborative relationships can be achieved through early contractor procurement and, forward integration in the supply chain.

Competitive pressures and government regulations are examples of the third group, the institutional or industrial barriers that are derived from the organisation's industrial environment, potentially serving as serious barriers to change in general (Eriksson et al. 2008, 2009). Through establishing legislation, the previous barriers are even more supported.

The following section will focus on the latter for public procurement. Which institutional barriers are impeding the adoption of partnering in public sector projects? Legislation influencing public construction/procurement is examined to map the

obstacles to overcome/to challenge in order to implement future organising strategies in public construction projects to achieve through-life value.

INSTITIONAL BARRIERS

Although Eriksson et al. (2008, 2009) identified these institutional/industrial barriers as least critical, Phua (2006) found out that institutional forces far outweigh the importance of economical forces in determining partnering occurrence. A lack of strong institutional partnering norms in the industry largely explains why the implementation of partnering has remained patchy. Organisations are shaped by institutional norms and pressures such that common structures and patterns of collaboration between firms, copied over time, will become 'legitimate' and generally accepted practice (Osborn and Hagedoorn, 1997). Institutional forces that arise from specific regulatory institutions (e.g. laws, regulations) and normative and social norms (e.g. professional conformity, industry and societal expectations) will, to a certain degree influence business decisions and organizational actions. It appears that partnering has not achieved the status of 'proto-institution' where its practices, rules and technologies become so entrenched that firms choosing other practices, rules and technologies will become less competitive (Phua, 2006).

Public procurement legislation (PPL 1993 and PPL 2006)

Public procurement legislation aims to facilitate competition and non-biased procurement decisions. Since public procurement cannot be grounded on trust-based negotiations and prior work experience, these laws are often seen as working against collaborative relationships (Ng et al., 2002; Naoum, 2003).

In the Belgian public procurement legislation as well, the factor competition and awarding on lump sum basis is already launched in article 1 (PPL 1993) and article 5 and 6 (PPL 2006). Together with article 15 and 16 (PPL 1993) renewed in article 24 and 25 (PPL 2006) the selection criterion is described as follows: the lowest or most economically advantageous regular tender will be selected; the emphasis is clearly set on the selection of the lowest tender price. Both the competition culture, in which early procurement of all key actors (supply chain integration) to a project is impossible and the tender price being seen as the only selection criterion, clearly impedes the adoption of partnering in public sector projects.

The new legislation of 2006 together with the royal decrees of 2011, provides through competitive dialogue possibilities, for limited invitation to a few trusted bidders, increasing the chances of lasting relationships in which actors can establish shared values and win-win attitudes, compared to the short term perspective of the open bid procedures (Eriksson et al., 2008). But even there in the few examples existing, price again represents at least 60% of the selection criteria, the other 40% embodies timing and materials used, which are both price-driven. They are not the soft parameters like resources and competences, reputation, collaborative ability, earlier experience of the supplier and shared values, Kadefors et al. (2007) suggested to use. The government urgently has to come up with specific partnering guidelines and policies.

Architects' act (1939)

The use of integrated project teams is also restricted by the monopoly status of the architect in Belgium, including the prohibition of collaborative working between architect and contractor because of the potential conflict of interests that would occur

(article 6 Architects act). This means that the Belgian architect, as an adviser and representative of the client, at all times has to preserve his incompatible relation with the contractor. The argument behind it is, he cannot control and work together with or be paid by the contractor at the same time. Through this act it is clear that the architect and the contractor can never fully collaborate and share gains as it is aimed for by implementing integrated project teams and more particular partnering.

This act of 1939, protecting the title and profession of architects is still in use today. It was modified fourteen times between 1969 and 2009 through establishing new acts and royal decrees. The most prominent was the act Laruelle, which offered architects from 2006 on the opportunity to practice their profession in a limited company, again without any involvement of incompatible professions allowed, i.e. the contractors. This new law also obliges architect to insure their professional indemnity and ten year liability, what was only a deontological requirement for the registration at the Chamber of Architects before. The architect is the only construction professional bound by law to insure his/her indemnity and liability. This results in a deep pocket approach: when disputes arise, consequently the architect is often seen as the party who can best bear the risks. Sharing and insuring the risks in an integrated project team expects more involvement, investment from the client and the contractor, which surely is seen as a barrier.

According to article 4 of the Architects act, Belgian clients are obliged to engage an architect whenever they initiate building activities that require a building permission, which are all projects that involve structural issues. This protection of the architect's function aimed at protecting the public interest (Van Gulijk, 2010). This means that in every construction project an architect is involved and subsequently a design contract is signed, because without a signed agreement between client and architect, the Chamber of Architects will not provide the 'visum', a document necessary to apply for the building permission with the authorities. In that design contract the architect has to make several commitments. They comprise at least (art. 4 Architects act): designing the project, delivering the plans and documents for the building permission, inspecting the execution on site and assisting the client at completion (Uytterhoeven, 2010). Article 21 of the 'Reglement van beroepsplichten' (16th December 1983) add to this duty that an architect can never accept an assignment only for making a design without the duty to control the execution, unless he can assure that another architect is engaged to provide that particular service. Like Egan stated (1998), these formal, rigid, contractual relations need to be replaced by an integrated supply chain system which improves productivity and profits.

A last consequence of this Architect act, but surely not the least, is that for many years now the Belgian architect has been/become the professional in charge in construction projects. It is not a surprise that the study of Black et al. (2000) states that consultants are less convinced of the partnering thought and appear to feel that partnering is simply a fad. According to the study they are less enthusiastic due to fears of loss of control. A change in the architect's attitude will be paramount, which as well is an example of the cultural barriers listed above.

Regulation concerning sustainability and energy efficiency

This legislation is changing at an inimitable tempo in Belgium. Taking on this challenge in team, would avoid overloading the work package of the architect and the incomplete bidding documents. These regulations should be seen as a driver, an

opportunity to implement partnering, not as a barrier, because the effort could be spread among all professionals involved (Post et al., 1994).

Other institutional barriers

Next to regulations, Craft (1991) reports on another barrier. Trade unions or professional bodies mostly have a conservative and defensive culture that inhibits change and encourages maintenance of the status quo. Van der Auwera (2010) aligns this to the conservative Chamber of Architects and their unwillingness to reform, while they are in perfect position to stimulate innovation in building organisation through their architect members.

The deep-rooted practice of using standard contracts may prevent partnering since it brings a formality that stifles good relationships (Barlow et al., 1997). Knowing that system-based trust is ranked as the most important trust factor among clients and consultants, this indicates that they rely strongly on satisfactory contract terms to enhance trust (Wong et al., 2004). At the same time these contracts increase opportunism (Lazar, 2000), since standard contracts are too rigid and do not emphasize collaboration and sharing of responsibilities and risks. Instead, they focus on the individual parties and their responsibilities, thereby driving a distance between them (Eriksson et al., 2008).

To finish alternative dispute resolution like adjudication (Murdoch and Hughes, 2008) is nearly non existing in Belgium. After the formal notice of a default, construction participants are used to bring disputes immediately to court, which obviously results in delays on site and requires extra financial resources (Essex, 1996). If construction parties want to establish partnering in Belgium this is another tradition to remove.

CONCLUSION

In the search for aspects preventing the adoption of partnering, the barriers were categorised in three groups: cultural barriers, regarding people and their attitude, organisational barriers concerning processes and routines and institutional/industrial barriers. For Belgian construction actors the latter was regarded as critical, because institutional barriers like legislation and regulations support, strengthen and, even form the cultural and organisational barriers. Public procurement law and the architects' act are considered as the largest obstacles.

In public procurement legislation, both the competition culture, in which early procurement of all key actors (supply chain integration) to a project is impossible and tender price seen as the only selection criterion, clearly impedes the adoption of partnering in public sector projects. In the few examples existing where more selection criteria are incorporated, price again represents at least 60%, the other 40% most frequently embodies timing and materials used. Both price-driven and are not the soft parameters like resources and competences, reputation, collaborative ability, earlier experience of the supplier and shared values, Kadefors et al. (2007) suggested to use.

The monopoly status of the architect, implied by the Architects' act generates formal, rigid, contractual relations which hamper collaborative incentives. It needs to be replaced by an integrated supply chain system to be able to improve productivity and profits (Egan, 1998). It includes as well the prohibition of collaborative working

between architect and contractor because of the potential conflict of interests that would occur. The architect has to preserve at all times his incompatible relation with the contractor, the argument behind it being, he cannot control and work together with or be paid by the contractor at the same time. Through this act it is clear that the architect and the contractor can never fully collaborate and share gains as is aimed for by implementing integrated project teams and more particular partnering.

Together with conservative professional bodies with defensive cultures, the use of contracts focussing on individual parties and their responsibilities, thereby driving a distance between construction actors and a lack of alternative dispute resolution, the government urgently has to come up with specific partnering guidelines and policies.

To end, the vision of Post and Altman (1994), to see opportunities in certain barriers, is worth investigating in future research. Removing all barriers is not always necessary to innovate/to change, studying barriers meticulously could also result in creating new opportunities.

ABSTRACT

The abstract text should not exceed over 200 words. The font set at Times New Roman 10 point for the abstract body and keywords only. The entire paper justified as this paragraph is set. The purpose of the abstract text is to capture the essence of the paper and the principal conclusions. Do not use the following phrases to describe your paper, "this paper will discuss"..."this report"..."the authors will discuss"... "the hypothesis is." Avoid writing in first person. A well-written abstract will provide the reader the objective of the paper without using such words. Precise specifications for laying out the paper and using this template will assist of the conference organizers in compiling the proceedings. Font sizes, paragraph formats and other details are specified so that proceedings can be presented in a consistent and professional style. This document is formatted according to the guidelines, in order to provide an example for authors.

Keywords: five keywords listed reflecting the contents of the paper, please use lower case and alphabetical sequence separated by commas, finishing with full-stop.

INTRODUCTION

The usual methods for boosting performance - process rationalization and automation - haven't yielded the dramatic improvements companies need because the focus has been on software or technology and not on the process itself, and often it is not understood why companies and their employees perform the processes in the first place. In particular, heavy investments in information technology have delivered disappointing results, largely because companies tend to use technology to speed up outdated ways of doing business rather than evaluating and changing the processes or the ways they do business. Business cycles change often and if companies do not stay focused on their processes of how they deliver their goods and services to their customers through these changing cycles they will not survive. They leave the existing processes intact and use computers simply to speed them up (Hammer, 1990).

[1] email@asu.edu
[2] email@university.hku.hk
[2] email@asu.edu
[2] email@university.hku.hk

But speeding up those processes cannot address their fundamental performance deficiencies and inefficiencies (Hammer, 1990). Many of the management philosophies, approaches, techniques, designs, control measures and organizational structures we use today were created in a business environment that existed long before the advent of the computers. The entire focus was, and still is, on efficiency and control measures. The management buzzwords then and now are still the same; creativity, speed to market, efficiency in production, innovation, total quality management, and great customer service. The idea that technology simply makes our processes better is not supported, it's the process itself aided by computer technologies that determines desired outcomes and prescribed success. Thus the process must be revaluated and reengineered if the dramatic performance increase that are need are ever to be realized.

PROCESS REENGINEERING IN THE BUUSINESS SECTOR

Among the general business audience, however, the usage of reengineering has come to be near the middle of a broad spectrum of uses (Davenport and Short, 1990). So what exactly does reengineering mean? To some, reengineering means any attempt to change how work is done, even incremental change, of small, sub-functional processes. To others, process reengineering means an ambitious and extreme organizational transformation, where major organizational changes occur simultaneously in philosophy, strategy, approach, process, culture, information systems, and all other organizational arenas. "A 1994 survey of North American and European companies found that reengineering activity was quite prevalent at 69% and 75% respectfully, and at least one project under way. Of those not then doing reengineering, half were planning or discussing projects. In both Europe and North America, companies had more than three reengineering initiatives completed or under way on average. As reasons, they cited more demanding customers, increased competition, and rising cost as the primary drivers. In the same survey, companies were asked what processes they had addressed through reengineering. The most popular processes in North America were customer service (25% of respondents), order fulfillment (16 %), manufacturing processes (15%) and customer acquisition (Davenport and Short 1990)." So what happens to companies as they begin to reengineer their entire organizational processes? Many companies do take a "clean-sheet" approach to designing a process or starting from scratch with a new clean slate hoping to instill positive real change that will transform the organization and all its elements. The creative design teams attempt to imagine "the best of all processes", without regard to the existing constraints of people, information systems or company organizational factors such as philosophy, culture, management style and approach. Therefore there should be no surprise that the new process designs that many firms create are quite radical, with ambitious plans for new technologies, new skills, and new organizational structures (Davenport and Short, 1990). However, only a fraction of companies attain their change goals typically due to problems with implementation, due to time frames, and due to costs and personalities within the organization (Davenport and Short,1990).

PROCESS IMPORTANCE IN CONSTRUCTION

The construction management process is a necessary procedure in construction companies' execution of their business (Cheng and Tsai, 2003). A construction company that employs an inefficient and ineffective process management protocol and process structure will have a profound impact on its project performance,

financial performance and overall company success. However, most construction business owners today are not able to properly identify and determine a correct process because they are too far removed from the day to day operations and requirements of project management and current technologies associated with the process. Therefore, these current business owners fail to establish effective systems or processes or even be able to understand whether they are reasonable and effective. These problems result in a redundancy of business operations and are a waste of valuable human and time resources (Cheng and Tsai, 2003). They can render management ineffective to the degree that those individuals may not know how to improve their predicament (Cheng & Tsai, 2003). If management is better able to evaluate the existing management process and address deficiencies before the implementation of automation or the establishment of a standard operation process, the likelihood of computerization's success will be greatly increased (Cheng & Tsai, 2003). Therefore the process itself and its flow through the organization must be evaluated for efficiency, effectiveness and value. One way to determine this is to select a process that may need evaluating or reengineering and create a matrix of business functions and their link to human functions within the organizational structure.

WHAT IS A BUSINESS PROCESS?

A business process is a collection of related, structured activities or tasks that produce a specific service or product (Toor and Dhir, 2011). "There are three main types of business processes:

1) Management processes; the processes that govern the operation of a system. Typical management processes include "corporate governance" and "strategic management".
2) The next business process is operational processes; processes that constitute the core business and create the primary value stream. Typical operational processes are purchasing, manufacturing, marketing and sales.
3) The third and last business process is supporting processes; which support the core processes. Examples include accounting, recruitment, and technical support. The analysis of these business processes typically includes the mapping of processes and sub-processes down to activity level (Toor and Dhir, 2011)."

A business process model is a model of one or more business processes, which defines the ways in which operations are carried out to accomplish the intended objectives of an organization. (Toor and Dhir, 2011) One of the benefits of business process modeling is the actual function of modeling and simulation functionality that allows for pre-execution of "what –if" scenarios that then leads to post-execution optimization based on the analysis of actual "as-performed" metrics as noted in the business function process matrix. The key to business process reengineering is for organizations to look at their business processes from a "clean slate" perspective and determine how they can best construct these processes to improve how they conduct business (Toor and Dhir, 2011).

A major continuing stimulus for reengineering has been the emerging innovation and user friendly development of sophisticated information systems, networks and touch pad technology that enable us to manage numerous processes simultaneously, with greater ease than in years past. Leading construction companies are becoming bolder

and more aggressive in using this technology to support and maintain innovative business processes, win strategies, and a competitive advantage in their market place rather than trying to refine ways of doing the same old project management processes. It is a holistic management approach that promotes business effectiveness and efficiency while striving for innovations, flexibility, and integration with technology (Toor and Dhir, 2011). As organizations strive for attainment of their objectives, business process management attempts to continuously improve processes – the process to define, measure and improve your processes – a "process optimization" process (Toor and Dhir, 2011).

WHAT ARE THE CRITERIA FOR BUSINESS PROCESS MANAGEMENT?

What are the criteria for business process management? It entails several approaches: documenting the process to obtain an understanding of how work flows through the process, the assignment of process ownership in order to establish managerial accountability, manage the process to optimize some measure of process performance, and improving the process to enhance product quality or measure to process performance (Gulledge and Sommer, 2002). Business process management is actually an event driven process wherein one engages in the planning of an event and manages an event from start to finish and its interactions with other simultaneous events. To understand the events that occur or should occur, an evaluation process must take place.

The evaluation is undertaken to inform decisions, clarify options, reduce uncertainties, and provide information about programs, policies, and processes, all within contextual boundaries of time, place, values, and politics (Patton, 1990). This information is used to make decisions that reduce uncertainties, improve effectiveness and identify reasons for success or failure (Vakola and Rezgui, 2000). Evaluation gives reliable, independent assessment of the results of continuing activities and information on which decisions can be based (Vakola and Rezgui, 2000). Managers need to understand the effects of their activities in order to look for alternative approaches and test their results (Caulley, 1993). M. Scriven introduced two different types of evaluation in his book *The Methodology of Evaluation*, the first being "formative evaluation" which is based on the collection of information that can be used primarily for program development and improvement, and the other is "summative evaluation" whose primary purpose is to make an overall judgment about the effectiveness of a given program (Scriven, 1967). According to Sherwood-Smith (1994), formative evaluation in business process reengineering aims at impacting, in an incremental way, decision making throughout the reengineering process, whereas summative evaluation is used to validate or reject the final outcomes. Evaluation is a problem solving process or a process that provides information for decision making (Wholey, 1994). Additionally, evaluation relates to knowledge construction and capacity building (Segone, 1998). For example, the use of "lessons learned" at the end of a project is a critical success factor in the construction industry (Vakola and Rezgui, 2000). Evaluation also facilitates the process of knowledge transferability to similar situations (Vakola and Rezgui, 2000). Can the processes be duplicated by others and have the same outcome? Lesson are transformed into knowledge when they are analyzed, systematized, disseminated and internalized within an organization through evaluation processes (Segone, 1998).

As reengineering activities focus on outdated and inefficient processes in order to make changes that achieve the greatest impact, prior to execution, the present process must be reviewed to locate process barriers in order to ensure their targeting in process redesign (Cheng, Tsai and Lai, 2009). Process value, used to evaluate process performance, can be viewed from either of the following two perspectives: efficiency per unit of cost or efficiency per unit of time (Cheng, Tsai and Lai, 2009). Time is an important factor that impacts the overall cost in providing goods and services in that the longer the process takes to accomplish, the higher the financial price demand, therefore the less competitive a company can be. Although evaluation can facilitate the change process, and is a major asset in the business process reengineering effort, there are many factors that can potentially obstruct this process; fear of being blamed, fear of being shammed, fear of uncertainty, fear of politics, and fear that the evaluation will be unfair (Patton, 1990). "Process orientation has one fundamental problem: requiring organizations to formalize their business processes down to the task-level details required by BPM (Business Process Management) technology. But that rationalistic/mechanical approach is often infeasible or harmful to organizational behavior. First there is a trade-off between responsiveness and formalization. High formalization makes organizations less responsive to turbulent environments. Low formalization naturally increases responsiveness, but challenges the capacity of the BPM systems to effectively coordinate business activities. We also find a trade-off between detail and ambiguity (Antunes and Mourao, 2011)." Most service-oriented organizations deal with great levels of informality, variability and ambiguity (Saastamoinen, 1995). Therefore many work processes must be kept at very generic and often vague levels of detail (Antunes and Mourao, 2011). On the contrary, BPM systems often require detailed specifications about what, how, when, who and where activities should be executed (Antunes and Mourao, 2011). Besides these relatively confined issues we should also take a broader view of the organizational forces shaping BPM technology (Antuens and Mourao, 2011). Several researchers observed that computerization has been increasing and organizations are becoming more dependent on computer technology (Hollnagel and Woods, 2005). All along with this increasing dependency we find out that organizations and computing technology have become more complex, adopting new transformation processes, higher temporal demands, wider distribution and span of control, increased skills level and more intensive decision-making abilities (Hatch 2006). The consequence of this trend is that organizations have become more prone to hazards (Perrow, 1994). The transformational process mainly represents the application of conducted operational analysis and process modeling. The primary purpose of operational analysis is to define a processes operational category and hierarchical structure. Process modeling is used to provide a comprehensive explanation of the relationship between operations (Cheng, Tsai and Lai, 2009).

In conclusion, business process management is actually an event driven process wherein we engage in the planning of an event and we manage an event from start to finish and their interactions with other simultaneous events. It is a method for boosting performance that requires constant evaluation and does not simply get better by adding technology to it in order to produce events faster. Therefore, processes must be evaluated and reengineered if we are to transform our organizations, change business strategies, and culture. The evaluation and reengineering of our processes is due to more demanding clients, order fulfillment, manufacturing ability and speed to distribution and customer acquisition. It drives every aspect of our business and how

the business operates and our clients interface with it. It is the currency by which we exchange with our customers for goods and services. The analysis of our business processes typically involves mapping of our processes and sub-processes down to the activity level then documenting it for evaluation. A business process model can used to help better understand and define the ways in which we operate that can lead to process optimization. Evaluation is a problem solving process that provides information to enable us to make better decisions. Therefore the process itself and its flow through the organization must be evaluated for efficiency, effectiveness and value. In all the literature reviewed, there was no mention of "balance in process management" meaning how to identify and quantify the process to determine if it is too much or too little for the organizational structure and the human and time resources to effectively and efficiently execute. Therefore, more research and study is required to truly gain an understanding of the balance in process management and its effects on the organization and its ability to successfully meet the ever changing competitive business climate in which we work.

However, the authors have taken the liberty of evaluating a process in the organization in which they work to evaluate the overall process and work flow of how an estimate of a project is performed and hereby provide an approach to consider in evaluating the balance of processes within any organization (Figure 1). It begins by looking at the work flow process of estimating a project and the simple steps required to arrive at a complete project budget or GMP, guaranteed maximum price budget.

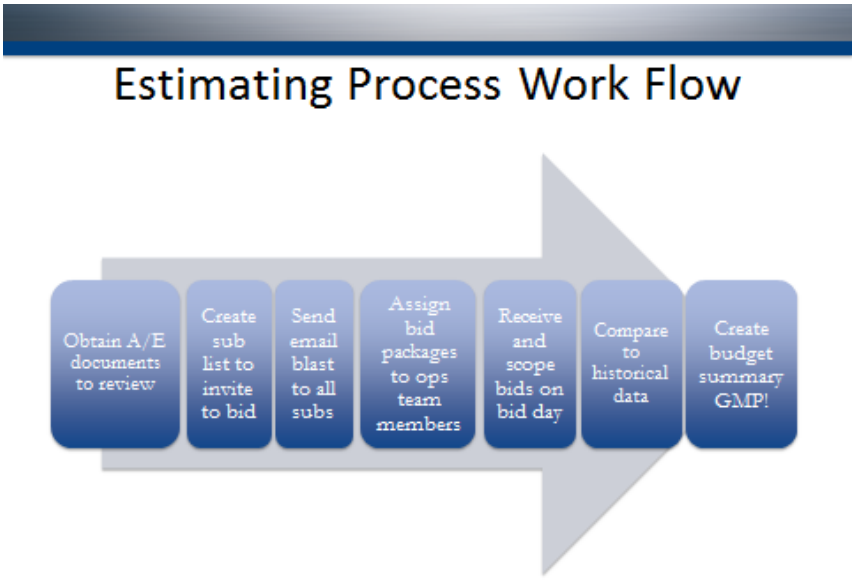

Figure 1. Estimating Process Work Flow

In order to understand the graph above and how to create a budget summary or GMP, one must first comprehend the desired outcome from the process; the desired outcome is a complete and competitive, line item budget summary, with good scope coverage in every trade. Once it is known what the desired outcome is we can start the process with the end in mind. Each step must be evaluated as to its importance in the process, who does it, how long does it take them to complete, and how many people does it take to complete the task, does it add value to the process or budget and is the

information produced accurate and complete? Notice in the table below the correlation between the tasks and the scoring criteria. The scoring criteria will help us see if our process work flow is balanced.

Table 1. Process Flow Evaluation

			Estimating Process - Work Flow				
Criteria	Obtain A/E Documents	Create sub contractor list to invite to bid	Send email blast to all subs	Assign bid packages	Receive and scope bids	Compare to historical data	Create budget summary / GMP
Who Does it	1	5	1	5	5	5	5
How long it takes	5	5	5	3	5	3	5
Number of people	5	2	5	5	5	3	2
Does it add value?	5	5	5	5	5	5	5
Accuracy	5	5	5	5	5	5	5
Completeness	5	5	5	5	5	5	5
TOTALS	**26**	**27**	**26**	**28**	**30**	**26**	**27**
* score on a scale of 0 - 5 of level of importance with 5 being the highest or most important							

CONCLUSION

Process engineering requires have the proper amount of structure to afford maximum efficiency and governance, but at the same time must allow for critical thought, day-to-day flexibility for execution, and not restrict value-based behavior. The body of literature seeking to propose ways to measure process balance as having either too much structure and rigidity, too little, or just enough is nearly non-existent. A full evaluation must include organizational, personnel, and process components. This field of study currently affords much room for discovery.

MULTI-FIRM FEEDBACK AS A BENCHMARKING TOOL –THE CASE OF FINLAND

Sami Kärnä[1], Liisa Lehtiranta[2] and Tuula Raman[3]

[1&2]*Aalto University, School of Engineering, BES Research group, PO Box 13300, FI-00076 Aalto, Finland*

[3]*Construction Quality Association (RALA), Tapiontori 1, 02100 Espoo, Finland*

ABSTRACT

Multi-firm project feedback supports the efforts of construction companies to establish industry benchmarks and to improve performance. Feedback indicates project success and thus complements traditional performance measures. The construction industry needs effective methods for gathering and utilizing information that can raise awareness of and steer reactions to operational problems and conflicts. This paper describes the features and benefits of a multidirectional project feedback system and the accumulated results for the Finnish construction industry. The multi-directional feedback system enables project participants to evaluate one another's performances at different stages of a project and therefore enables versatile benchmark comparisons between projects and between companies. The main performance factors, including project management, staff, collaboration, and goal accomplishment, were analyzed for project consultants, main contractors, subcontractors, and architects/designers. The analysis is based on approximately 800 feedback entries, representing 788 projects, over a 5-year period during which the feedback system was used. The project feedback data provide both a national-level overview of the performance of the Finnish construction industry and a base-level benchmark for various parties involved in this industry.

Keywords: client satisfaction, feedback, performance improvement, performance measurement, project participants' satisfaction.

INTRODUCTION

Growing competitive pressures and the introduction of initiatives to improve productivity, quality and efficiency are leading many construction organizations to rethink their construction processes. The complex nature of the construction process, changes in project organization, the uniqueness of each project and the variability of the objectives of the parties involved complicate evaluations of project outcomes and emphasize the need for effective and efficient evaluation systems (Kumaraswamy and Thorpe 1995).

The aforementioned factors have raised the awareness of performance measurement strategies (benchmarking) among the majority of construction organizations

[1] sami.karna@aalto.fi

(Mohammed 1996). To improve performance and management, companies should use multiple tools to measure their ability to develop and monitor products and services (Garvin 2001). Feedback from project clients and participants can be used as a performance measurement tool during the construction process and collaborations.

Among the most common benchmarks used in the construction industry are key performance indicators (KPIs). KPIs are performance standards that focus on factors critical to the success of an organization or project. With the help of KPIs, companies can identify the best practices for developing their operations (CII 2004). Recently, soft KPIs such as customer satisfaction and project participants´ satisfaction have been investigated. These indicators complement traditional key performance indicators such as cost, schedule and quality. Thus, a holistic view of performance measurements in the realm of multifaceted construction projects has been acknowledged (Dainty et al. 2003; Leung et al. 2004; Nzekwe-Excel 2012; Lehtiranta et al. 2012).

However, the industry seems reluctant to adopt benchmarking, mostly due to the difficulty of collecting and utilizing relevant data (Mohamed 1996). In addition, current management frameworks and tools do not comprehensively correspond to the characteristics of project networks (El-Sheikh and Pryke 2010) or the multi-faceted substance of project success (Jugdev and Moller 2006). The challenge to industry is then to develop and adapt effective methods for gathering and utilizing information to make organizations aware of operational problems and conflicts. In Finland, a solution that responds to the challenges of multi-organizational project feedback and industry-wide benchmarking has been proposed and tested. As a common system for parties in the industry, the project feedback system promotes performance improvement, customer orientation and collaboration.

This paper introduces the features and benefits of a multi-firm project feedback system, which has been used to measure the mutual performance of project participants in the Finnish construction market since the year 2007. The accumulated project performance evaluation results, which are based on 5 years of use and 800 projects in the Finnish construction industry, are introduced and discussed.

MULTI-FIRM FEEDBACK AND BENCHMARKING

Mohamed (1996) described three types of benchmarking: 1) internal benchmarking, in which a construction organization attempts to identify internal areas of improvement by comparing its business operations with those of its competitors, thereby establishing new targets; 2) project benchmarking, in which a construction organization assesses the performance of its projects to meet customer requirements, measure productivity rates, and validate and maintain its databases; and 3) external benchmarking, in which the industry as a whole attempts to increase its productivity by applying tools and techniques that can be used by other industries. Benchmarking solutions can encompass any combination of these types. The keys to benchmarking in the construction industry are tailoring solutions to specific projects and multi-organizational working cultures and efficiently interpreting data to improve businesses, firms, and the industry as a whole.

Project feedback is a rich source of data for benchmarking. A previous analysis of industry-wide benchmarking results showed that the satisfaction of a participant with the performance of other participants reflects the success of a project (Lehtiranta et al. 2012). This information can then be used in performance measurements and to inform

early reactions during a project. Another report demonstrated that benchmarking results can be used to compare satisfaction levels with various performance components in different procurement methods (Lehtiranta et al. 2011). The perceptions of the owners, project consultants, designers and contractors of the quality of their relationships have been shown to vary significantly, even within the two directions of feedback in one relationship (Lehtiranta et al. 2011).

Significant differences are apparent in the performance measurements of different project types. According to a recent study (Kärnä et al. 2011), infra-project feedback differs from that of other project types, particularly in the perceptions of clients and designers of a consultant's performance and the consultant's evaluation of the contractor's activities, which vary for all three project types. This result reinforces the theory of differences between various types of construction projects, and research and practical development work should focus on the special features of each project type across the entire field of construction.

From the benchmarking perspective, project feedback has two main strengths. Initially, it can focus on an organization's core areas of business to help achieve the greatest added value for any improvement strategy. Second, after determining how a particular production processes compares to others, it can focus on investigating how those with superior performances achieve their performance rates (Kärnä 2009). Project feedback is also a management tool, rooted in the business environment, that can be used to identify changes needed in production processes to improve performance. In brief, it involves analyzing an existing situation, identifying and measuring factors critical to the success of a production process, comparing them with the success factors of other companies, analyzing the results and implementing an action plan to improve performance.

Multi-organizational involvement in project feedback and benchmarking solutions in the construction industry is a natural requirement for several reasons. Construction project success depends on the ability of multiple firms to work together satisfactorily (Lehtiranta et al. 2012) and to manage risks and learning (Cherns and Bryant 1984). The project organization can be described as a *rendezvous,* in which the participants` abilities to create value for one another and the project as a whole are key elements of success. Therefore, project feedback should cover the most important parties in the supply chain and be bi-directional. Feedback should be properly used to provide rich information for risk management and learning both during and after a project.

Typically, project participants evaluate projects from their individual perspectives and use their own criteria to measure success. To attain project goals, a systematic evaluation of organizational performance is required to provide feedback and thereby guide the behavior of participants (Liu and Walker 1998). Because the performance of each participant in a construction project is interdependent, the mutual performance of project participants must be evaluated as an indicator of the ability of participants to provide value for one another.

THE CASE OF FINLAND – MULTI-FIRM BENCHMARKING TOOL

Development of the tool

The basic version of the project feedback system for the Finnish construction industry was developed between 2005 and 2008 as part of a joint project between the University of Technology, Construction Quality Association RALA and several industry and association partners. RALA operates the system as a joint association that represents clients, contractors, and consultants. Its aim is to improve the prerequisites of construction quality by using certificates of competence, certificates of quality systems, and a project feedback system for clients and construction companies.

During development, the following requirements and system properties were determined to be essential.

- The system should cover the entire industry and use a versatile Web interface
- The central participants of the project should be involved in the system
- It should be possible to give and receive feedback throughout the various stages of a project and to utilize the feedback during a project
- It should enable multipurpose benchmark comparisons
- It should be able to be adapted to different projects and forms of implementation

Main features of the tool

The basis of the feedback system is standard evaluation, in which the main participants evaluate one another's performances. The system identifies five alternative roles for participants: client, project manager/consultant, architect/designer, main contractor, and sub-contractor. Any project participant can sign up as the master user of the feedback system and then invite others to join. The multi-directional network of feedback flows in the system is illustrated in Figure 1.

The evaluation consists of 15 different electronic questionnaires, which are specific to each evaluation flow, such as client evaluations of a main contractor. The questionnaires can be adapted to fit the needs of a project. Feedback related to the operations of other project participants is provided after participants respond to statements about performance on a 5-point Likert scale, where 1 and 5 represent very low and very high satisfaction levels, respectively. Specific questions depend on the flow of feedback, and the common evaluation topics are:

- Project management
- Collaboration
- Staff
- Goal accomplishment

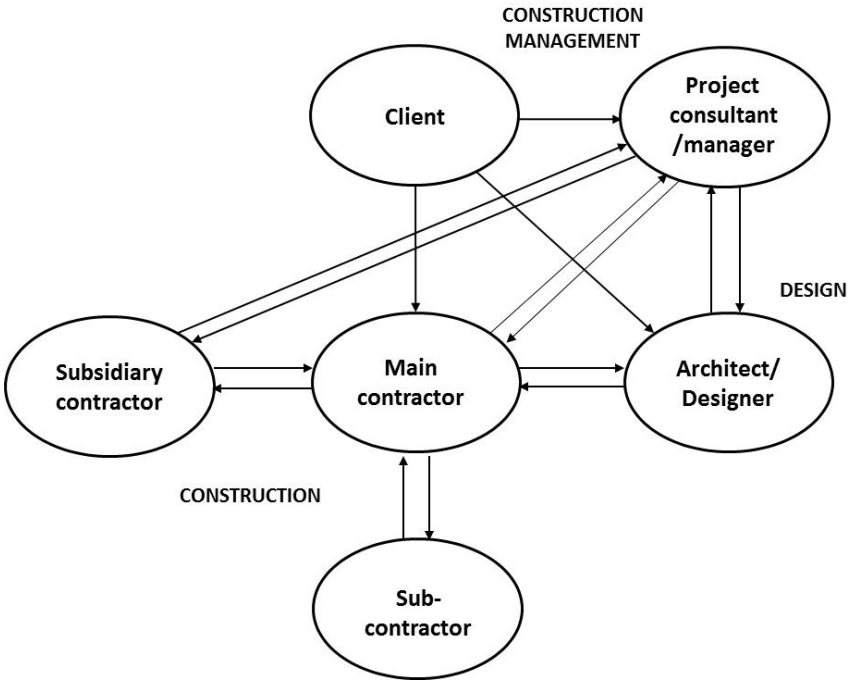

Figure 1. The multi-directional network of feedback flows in the feedback system.

Reporting and benchmarks

The feedback system offers clear, real-time benchmarking reports, which can be tailored to a company's products and processes. By comparing various background variables, a company can compare its performance with that of similar companies in the market.

Figure 2. Illustrative dashboard of a company's benchmarking results based on its project portfolio.

THE CASE OF FINLAND – MULTI-FIRM BENCHMARKING RESULTS

The project feedback system has accumulated 3191 performance evaluation results, representing 788 projects over a period of 5 years. The multi-directional evaluation results are summarized in Table 1 by main categories. Values are feedback flow averages on a 5-point Likert scale, where 1 and 5 represent very low and very high satisfaction levels, respectively. The values in the table form industry-wide benchmarking results, which enable individual companies to compare performances. Higher values indicate and showcase a competitive advantage for the specific factors.

Table 1. The national benchmarks for clients, project managers, main contractors, designers, and sub-contractors in the Finnish construction industry. Based on multi-directional evaluation results.

Evaluator		Project manager / consultant	Main contractor	Architect / designer	Sub-contractor
Client	→	PM (3.8) CO (4.0) S (4.0) G (3.8) TOT (3.9) n=121	PM (4.0) CO (4.2) S (4.1) TOT (4.1) n=620	PM (3.7) CO (3.9) S (3.9) TOT (3.8) n=123	N/A
Project manager / consultant	→	N/A	PM (3.9) CO (4.1) S (4.1) E (4.1) G (4.0) TOT (4.0) n=941	PM (3.7) CO (3.8) S (3.8) G (3.7) TOT (3.8) n=215	N/A
Main contractor	→	PM (3.9) CO (4.3) S (4.3) TOT (4.1) n=282	N/A	PM (3.4) CO (3.8) S (3.6) G (3.4) TOT (3.6) n=211	PM (3.7) CO (4.0) S (4.0) G (3.9) TOT (3.9) n=191
Architect / designer	→	PM (3.9) CO (4.0) TOT (4.0) n=163	PM (3.9) CO (4.0) S (4.0) TOT (4.0) n=238	N/A	N/A
Sub-contractor	→	N/A	PM (3.9) CO (3.9) S (4.0) TOT (3.9) n=113	N/A	N/A
Areas of evaluation		PM=Project management E = Environment	CO=Collaboration TOT=Overall satisfaction	S=Staff	G= Project goals N/A= not available for evaluation

The results show that the general levels of performance evaluations for project participants in the Finnish construction industry are high, as represented by a score

just under or above 4. Although main contractors typically receive some of the highest evaluations and designers receive some of the lowest, the differences are minimal in this aggregate benchmark. The project management performance of the participants can be identified as a factor yielding somewhat lower evaluations than the other factors for a company. Conversely, staff members and their ability to collaborate are generally highly evaluated.

CONCLUSIONS

Benchmarking is a tool that companies can use to continuously improve their performance. In the construction industry, which is project based, multi-firm project feedback can and should be used to identify participants' levels of performance and development needs. As part of the complex and dynamic construction industry, multi-directional project feedback responds to the needs of performance measurements and corresponds to wider perceptions of project success, including satisfaction with the process. Project feedback can be used on several levels: to detect performance problems and identify improvements during a project for the purpose of risk management; to identify improvement needs after a project for the purpose of learning; to analyze project portfolios for the purpose of business improvement; and to accumulate results in a feedback database for the purpose of industry analysis.

In this paper, a multi-firm benchmarking tool and national benchmark levels for the main parties in the Finnish construction industry were introduced based on seven years of research and five years of multi-directional performance measurements. In Finland, multi-firm benchmarking supports the performance of consultants, main contractors, architects/designers, and sub-contractors of a construction project, aids with client orientation, and contributes to collaboration. Companies that exceed the national benchmarks have a competitive advantage.

PRE-DEPARTURE AND POST ARRIVAL CROSS-CULTURAL TRAINING FOR AUSTRALIAN PROJECT MANAGERS WORKING IN THE UAE

Sabina Cerimagic[1]

[1]*Bond University, QLD, Australia*

ABSTRACT

Cross-cultural training at different times of the expatriate's overseas assignment is not only useful but it is critical to the expatriate's success overseas. If western cooperation's such as Australian international companies are to provide expatriates with cross-cultural training companies could reduce or even prevent expatriate failure. This research was based on six case studies, which were all Australian international companies that also operate in the Middle East. The method used was semi-structured interviews. If expatriates are to be successful in the United Arab Emirates (UAE) they need to be prepared with appropriate, adequate and up-to date cross-cultural training. For the cross-cultural training to be most effective it needs to be provided at the three most critical stages; pre-departure, on-site and have a repetition stage once the expatriates have been in the new host country for a few months. The reason for having three distinct stages of cross-cultural training is because expatriates will have to deal with different issues at different times of their overseas assignment, this way the training will be most relevant and effective for the expatriates. This research points out that the most beneficial cross-cultural training is training that is offered at different stages/times of the expatriate's overseas assignment.

Keywords: Australian project managers, Cross-cultural training, United Arab Emirates (UAE) and pre-departure, on-site and repetition stages.

INTRODUCTION

According to researchers such as Foster (2000) and Caligiuri, Phillips, Lazarova, Tarique and Bürgi (2001) it has come to the attention of companies that cross-cultural training is critical if their expatriates are to be successful in their overseas postings.

As to date there is no one definition that constitutes expatriate 'failure'. An expatriate is not only considered to have failed if they return home prematurely but also if they continue to stay in the host country but they damage business relationships and delayed productivity only to name a few (Bennet, Aston and Colquhoun, 2000).

[1] sacerima@bond.edu.au

Companies can lose up to a quarter of a million dollars for every failed expatriate (Morris and Robie, 2000). There is also the non-financial effect of failure. These effects include loss of business opportunities and damage to the company's reputation. There are also psychological issues associated with failure. The expatriate will, most likely, have lower self-confidence and damaged self-esteem.

As pointed out earlier, there are many reasons for expatriates failure and in many cases it is not the technical incompetence of the expatriate but more numerous under laying causes. Such as culture shock, where the expatriate cannot adjust and adapt to the physical, emotional and environmental cultural differences. The expatriate may not have personality skills for cross-cultural interaction which would cause the expatriate to have adjustment difficulties (Tung, 1981; Baumgarten, 1995; Bhagat and Prien, 1996). Hence, cross-cultural training is the key to help expatriates to adjust and adapt to a new culture faster and more effective.

Despite the evidence that with appropriate and sufficient cross-cultural training expatriates are more likely to succeed many companies is still not offering cross-cultural training. Bhagat et al., (1996) estimated that about 30% of the companies offer some type of cross-cultural preparation; most of those training sessions are in fact only 1 day briefing sessions.

There are many reasons why companies have been reluctant to offer cross-cultural training; some of those reasons are that there is not enough time for training, since the time between selection and departure is short. As well as, the cost associated with offering cross-cultural training is high. Yet, there are many companies that choose an expatriate based on their technical competence and they believe that expatriates who operate well at home will be effective and successful regardless of location (Kealey and Protheroe, 1996; Selmer et al., 1998; Morris et al., 2001).

However, companies fail to realise that organisations are becoming more diverse, business dealings continue to cross international boundaries and according to researchers such as Littrell et al., (2006:363) "multicultural training has expended beyond the arena of expatriate employees".

Back in 1982 Church proposed the U curve adjustment theory to explain why cross-cultural training can help expatriates adjust to a new and unfamiliar environment. According to Church (1982) adjustment is a function of time and that is what the U curve of adjustment theory demonstrates. For example, in the beginning stages of the overseas assignment the expatriate is excited and optimistic but as the assignment progresses culture shock kicks in and there is a drop in the level of adjustment and this can be very frustrating to the expatriate. However, if the expatriate has received appropriate and adequate cross-cultural training that individual will be able to recover, deal and adjust better to the new environment. Hence the U illustrates that expatriates will have different experiences within the assignment depending on the time when period. There for cross-cultural training should not be one-off event, but it is a process and it could be tailored to the period of adjustment the expatriate is at (Church, 1982; Selmer et al., 1998).

In fact Selmer et al., (1998) proposes that cross-cultural training should be structured in a way that would match up to the adjustment stage that the expatriate is at. The reason being that the training provided has a different impact based on the expatriate's psychological receptivity to the new culture and the phase of the assignment.

The Purpose of Cross-cultural Training

The whole point of cross-cultural training is to prepare expatriates for their overseas assignment so that the expatriates have a higher chance of success (Black, et al., 1990; Baumgarten, 1995; Forster, 2000).

According to researchers such as Baumgarten (1995) and Bennet et al., (2000) cross-cultural training should provide expatriates with knowledge, skills and abilities which can unable those individuals to adjust more quickly and efficiently to the new environment and to be more effective in business dealings. Additionally, cross-cultural training aims to equip the expatriates with knowledge required to understand the host national's behaviour without judging it and to adapt to it.

Cushner and Brislin (1999) propose four goals that cross-cultural training should consist of. Those goals are:

1. To help expatriates overcome obstacles that my limit them to perform at their full potential while on the overseas assignment.
2. Provide them with appropriate tools which can be used to build relationships with host nationals
3. To be able to successfully complete work related tasks
4. Teach them skills which will help them to deal with stress more effectively

Cross-cultural training that has those four goals imbedded in it will help expatriate's in developing the necessary skills that are necessary for a faster and more efficient adjustment to the host nation.

According to literature in the last past 30 years there have been wast amounts of literature looking at the effectiveness of cross-cultural training. Researchers such as Littrell, Salas, Hess, Paley and Riedel (2006) came to the conclusion that cross-cultural training is important. In fact they believed that cross-cultural training can facilitate success on expatriate assignments effectively.

Cross-cultural training is very diverse and useful not only at preparing expatriates for overseas assignments but also for training domestic employees in how to work with multicultural teams. As well as, it can help domestic mangers in improving cross-cultural avidness of domestic workers so that they can interact with individuals from diverse cultural backgrounds (Priest, Burke, Salas, Littrell, Hess, and Riedel, 2006).

Many companies have realised that cross-cultural training is vital for the success of their mangers, which positively reflects on the company's as well (Foster, 2000; Caligiuri, et al., 2001).

Effectives of Cross-cultural Training

According to Selmer et al., (1998) studies conducted on the effectiveness of cross-cultural training point out that cross-cultural training improves expatriate performance on an overseas assignment. Calgiuri et al., (2001) believe that since cross-cultural training helps expatriated adjust to a foreign culture faster that in turn it has a positive effect on the overseas assignment too, the expatriates tend to be more successful. Cross-cultural adjustment is positively related to performance and it minimises early return rates (Deshpande and Viswesvaran, 1992). Kealey et al., (1996) also found support for the viewpoint that cross-cultural training promotes and enhances skill development.

 ISBN: 978-1-84219-840-7 .

Many researchers in the area of cross-cultural training have proposed three categories of skills that expatriate need to possess in order to be successful in the new culture.

Those skills are:

1. Self maintenance skills,
2. Interpersonal skills and
3. Cognitive skills

Deshpande et al., (1992) believe that there is a positive link between those three skill sets and cross-cultural training. In particular, cross-cultural training is positively linked to self-development, the interpersonal skills help expatriates establish interpersonal relationships with the host country nationals and the cognitive skills help develop and nature that relationship.

Black et al., (1990) conducted a meta-analysis of 29 studies which dealt with intercultural training and the results reviled that cross-cultural training is positively linked with a feeling of overall well-being and development of self-confidence. The research also reviled that cross-cultural training had an overall positive effect on interpersonal skill and it was also positively linked to cognitive skills development. In addition, Morris et al., (2001) too did a meta-analysis which reviled that cross-cultural training and expatriate performance are positively related. Hence, the results from those two meta-analysis indicate that cross-cultural training is an effective and useful tool which can facilitate expatriate success.

RESEARCH METHODOLOGY

This research was based on semi-structured interviews. It was started off by selecting 6 case studies, which are all Australian international companies that also operate in the Middle East. First of all the researcher had to research Australian international companies which also operate in the UAE. After the potential companies have been selected the researcher emailed the company's directors and CEOs. The emails that were sent out introduced the researcher and the research and it asked if the individuals that have been emailed would be willing to participate in the study. The emails were received well and most companies were willing to be part of the research.

In some cases the directors and CEOs were the ones interviewed and in other cases the directors and CEOs recommended employees who were best suitable to answer the questions asked as accurate as possible. The snowballing technique was used to extend the sample, this involved asking each interviewee if there is anyone they know off who would be useful for this research, so that the researcher could interview those individual too (Green, Kao and Larsen, 2010).

Once the interviews were transcribed and analysed any area that needed more information or explanation was collected by contacting the participants by email and asking them the relevant questions. This provided a clear statement of the answers and sound documentation for each study.

FINDINGS

Any cross-cultural program should focus exclusively on the UAE culture, religion, and on how to practice project management in the UAE. This program would have to cover laws in the UAE, leadership and ethics. Emiratis take business personally, so it makes sense to learn as much as possible about the host country's culture in order to be able to avoid misunderstandings and conflict. This research has uncovered three stages of expatriate training; the pre-departure stage, on-site stage and the repetition stage.

Once the cases studies have been analysed, three stages of cross-cultural training emerged. The results will be represented in three different stages; the pre-departure stage, the on-site stage, the repetition stage.

The Pre-departure Stage

The literature strongly advises that cross-cultural training should be provided to expatriates before they are sent overseas to work. Adequate and appropriate cross cultural training will prepare expatriates to deal better with the new and unfamiliar environment. Additionally, proper pre-departure preparation will give the expatriates an idea of what to expect in the new location to reduce the effects of culture shock.

This first stage was named "the pre-departure stage" and this stage is an introduction to the new culture and society.

The training at this initial stage should cover; geography, some history, an introduction to the religion Islam, basic Arabic, a summary of Arabic body language, work place communication culture and lifestyle. Additional, Arabic mannerisms and cultural awareness of specific items that could easily offend the Muslims should also be included. These issues are given in more detail below.

Cultural as well as business etiquette needs to be learned before starting to do business in the UAE. The information provided must be relevant and useful. Most of the challenges are due to the lack of knowledge on how things are done in the UAE compared to Australia. Those mental challenges could be avoided or minimised with appropriate training and preparation of expatriates. A social network and access to support groups would be helpful as well. The new expatriates can help themselves by talking to other expats currently living and working in the country which would help manage expectations and prepare them for their work.

Expatriates need to be provided with all the relevant and up-to-date information in order to be able to make an informed decision on if he/she wants to work and live in the UAE before they leave their home base.

The On-site Stage

The next stage should commence once the expatriates are in the country and "on-site". Cross-cultural training can help expatriates to better understand the culture, customs and work ethics of their host country. The on-site stage intends to assist expatriates enhance their knowledge and skills which in turn would help the expatriate practice in the unfamiliar host country and to be happier and more productive in their work. The case studies in this research indicated that on-site training was desirable. However, as the six case studies revealed on-site cross-cultural training is almost non-existent for most expatriates.

It is proposed that in the on-site stage expatriates should be given induction workshops. The induction workshops are similar to a refresher course for what was done in the pre-departure training workshops. The exception is that the induction should be spread over two half-days. The reason for spreading the induction workshop over two half-days is that a whole day is considered too long and people cannot concentrate and absorb everything if they have to spend a whole day listening to it. Therefore, having the induction for only half a day over two days would be much more effective. The program will be a specific culture preparation program, which would include a review of the construction industry in the UAE and how and if the technical side of work is any different in the UAE compared to Australia. Additionally, expatriates need to think about how to keep out of trouble when they get to the UAE and some of the specific technical skills required. Once they have been in the UAE for a while, they need a refresher course. The first course should be offered about 3 months after arrival, then 6 months and then once a year.

After the new expatriates complete their induction every new expatriate would get a mentor trough the mentoring, coaching and development system (MCDS). A mentoring, coaching and development system was recommended by the six case studies. It is believed that the MCDS would work in the company as a policy where before one can get promoted to the next job, the expatriate need to have completed fifty hours of coaching or mentoring. They would need to have successfully coached or mentored somewhere between seven to ten new expatriates before they can get promoted. This way expatriates will more likely do it willingly, and they may even volunteer.

Essentially the mentoring, coaching and development system is an advanced version of the buddy system. However, for branding and selling proposes it should be called the mentoring, coaching and development system (MSDS).
The MCDS has a number of very useful advantages.
Firstly, it will make sure that there is someone the new expatriate can approach and talk to, or if he/she has a problem or does not understand something there would be someone who can help. Secondly, this type of training acts as a repatriation phase for the mentor(s); this is why a mentoring program would be of utmost importance.
Additionally, having this type of support base and network is very important because the expatriate knows that he/she is not alone and there is someone who can help.

The Repetition Stage
At the repetition stage expatriates will be taking part in refresher workshops. After completing the refresher workshop (three months after arriving) this is followed by a workshop six months after that, and then another refresher course after one year. It is strongly advisable to take into consideration feedback from the nationals on what can be improved in the workshops and to try and implement it; this will help improve the training workshops.
According to research such as (Luthans and Doh 2009) many host country nationals would like to see changes and improvements in some styles of western expatriate managers. Those changes include the expatriate manager's leadership, decision making, communication and group work. In terms of leadership, the following changes would be desirable; expatriate managers need to be friendlier, available and respect subordinates and their suggestions. In terms of decision making, the host

county nations would like to be involved in the decision making process, especially those who will be affected by the decisions made. In terms of communication; the expatriate managers should be doing more group problem solving, with more teamwork as well as encouraging the exchange of opinions and ideas between managers and subordinates. This indicates that the training approaches used need to reflect both the industrial, professional, personal and the cultural environments.

CONCLUSION

There are a vast number of reasons why cross-cultural training is important. From a company perspective, if their expatriates are adequately trained for the overseas assignment they will be more successful by increasing the overall efficiency and profitability and the company will avoid losing hundreds of thousands of dollars. Cross cultural training helps expatriates to improve and be able to interact effectively with local people and co-workers and it helps expatriates to adjust to an unfamiliar environment faster than if they had no training at all. For developmental and functional reasons successful expatriate assignments are invaluable to companies. However, to this day most international Australian companies do not provide their expatriates with adequate, appropriate or up-to date cross-cultural training.

The lack of cross-cultural training or no training at all, is associated with higher expatriate failure rates.

This research has uncovered that the most effective cross-cultural training is training that is delivered in three different stages at different times of the overseas assignment. The reason being that at different stages of the overseas assignment expatriates encounter different experiences and require diverse types of training.

If cross-cultural training is to be offered, it needs to be offered at the pre-departure, on-site and repetition stages, for it to be successful. Additionally, the mentoring, coaching and development system is paramount to expatriates success.

STRATEGIC MANAGEMENT AS A PILLAR OF A MATURE QUANTITY SURVEYING BUSINESS

Pierre Oosthuizen[1]

[1]*Department of Quantity Surveying and Construction Management, University of the Free State, South Africa, PO Box 339, Bloemfontein, 9300, RSA*

ABSTRACT

The purpose of this study was to ascertain the possibility and search for an initiation point for development or growth. Development or growth should be directed at a main goal which could be called maturity. In order for a quantity surveying business to strive for maturity, the composition of a hypothetical mature quantity surveying business should be known. The question of what the pillars of a hypothetical mature quantity surveying business should be could then be pertinent. The research for this study is primarily based on a qualitative literature review which is supported by a quantitative empirical analysis. The qualitative literature research identified strategic management with four proposed main dimensions. The literature research set the foundation for this research. The value of this research is based on the support that it may offer future researchers to create a maturity model which could serve as a benchmark for quantity surveying businesses. Forty eight national and international quantity surveyors participated in the empirical study. Relevant academic books were studied during the literature study and many other sources which include interviews, internet articles, academic journals, etc. were used. The fact that this research mainly focused on South African conditions could be seen as a limitation. The information from this thesis could however be applied to international conditions in further research.

Keywords: Strategic management, Quantity surveying business, Macroeconomics, Maturity

INTRODUCTION

This paper serves to proof that a successful quantity surveying business should identify target markets and consider the threats, challenges and opportunities of those markets. Assessment of strengths and weaknesses and evaluating threats and opportunities in the market, might assist a business in composing a strategy or means to outperform its competitors.

Stewart, Kornberger and Pitsis (2005: 432) make the statement that almost all organisations have some version of excellence as their universal objective. This objective, as a version of excellence, could also be described as an aspiration to reach a mature state.

[1] oosthuizenpm@ufs.ac.za

According to Stewart, et al. (2005: 432) strategy has to answer the question, "*What value does the business add to its customers? Do the chosen purpose and the differences that enact it really add anything valuable to potential customers?*" In order for the business to answer these questions, self-examination could be prudent. The value of the product or service should reflect (equal or exceed) the price thereof.

Irons (1995: 118) articulates that strategies in their purest form are about clarifying what needs to be achieved and how to achieve it, all against the background of an understanding of the pattern of external events, and the threats and opportunities they present. The business should understand the markets and identify the demand for the product or service in order to gain an advantage over its competitors.

DEVELOPING AND IMPLEMENTING A STRATEGY

Summarising various definitions from various sources, it seems that strategic management is usually concerned with informed decisions regarding calculated arrangements of business structures, practices and procedures within a business, after all environmental variables have been valued and taken into consideration, with the incentive to reach a certain goal.

Hill and Jones (1998: 10) as well as Pearce and Robinson (2000: 4) state that strategic development should be initiated by top-management, since strategic decisions are integrated into several areas of a business's operations. These statements could be motivated by the fact that it is usually only the top-management that has the perspective needed to understand the broad implications of such decisions and the power to authorize the necessary resource allocations.

Stewart, et al. (2005: 432) support other research which suggests that there are three requirements needed to develop an effective strategy, namely

- A well articulated, stable purpose (mission and or vision);
- Establishing a difference with regard to one's competitors (goals); and
- Developing insights about how to create more value than other businesses (innovation and creativity).

The first step, of the strategic management process, according to Hill and Jones (1998: 6), is defining the mission and major goals of the business. The reason why the mission and major goals of a business could be important might be to provide the context within which strategies could be formulated.

Vision and Mission

Hill and Jones (1998: 6) define the mission as a statement which explains why the business exists and what it should be doing. The mission could also be described as "a plan of action". Katsioloudes (2006: 8) adds the word "purpose" to the definition and refer to different well known businesses where the purpose of the business could be derived from the mission statement.

The purpose of existence could be identified in many mission statements of the larger quantity surveying businesses in South Africa, like the following mission statement

from Davis Langdon: "The core purpose is to make a measurable difference to the value, cost and time of our clients' projects" (Davis Langdon, 2010: 4).

Pearce and Robinson (2000: 27) state that a business must first determine the basic goals and philosophies to shape its strategic stature, whether the business is developing a new business or reformulating a direction for ongoing business.

Pearce and Robinson (2000: 27) go further, articulating that the fundamental purpose that sets a business apart from other similar businesses, is its defined mission statement, because it embodies that business's business philosophy, with regard to its:

- Strategic decision makers;
- The image the business would like to display;
- A reflection of the business's self-concept;
- Indication of the business's main products and services; and
- Exhibiting the business's primary customer need satisfaction.

The mission statement could therefore be an important window to business processes for the business's stakeholders. As Hill and Jones (1998: 39) convey it, "the mission statement is a key indicator of how an organisation views the claims of its stakeholders". Hill and Jones (1998: 39) mention that the mission statement describes how a business intends to incorporate the claims of stakeholders into its strategic decision making and thereby reduce the risk of losing the stakeholder's support.

It could be argued that any mission statement could be better than no mission statement. It could also be argued that a good mission statement could retain existing and attract new stakeholders.

Hill and Jones (1998: 43) state that the mission statement should essentially cover the reason for the business's existence and what it will or should be in the future. It is important to note that Hill and Jones refer to the future. This could mean that the business should anticipate the possible shift in demand for products and services in the future.

For a business to make predictions, it might be necessary to do extensive research and set short-, medium- and long term targets for the business to meet. Hill and Jones (1998: 49) view the establishment of major goals as the next step in the formulation of a mission statement.

Goals

The definition of a goal, according to Hill and Jones (1998: 49), is a desired future state that a business attempts to realise. In this context, the purpose of goals might be to specify with precision what should be done if the business would like to attain its mission.

Goals could be described as "stepping stones" for the business to fulfil its mission. The goals could only serve as "stepping stones" if the goals are well-constructed and consequential to the mission of the business.

For goals to be meaningful it should have four main characteristics (Hill and Jones, 1998: 49):

- First, well-constructed goals should be precise and measurable. Measurable goals could give managers a measure to assess their progress toward attaining their goals.
- A second characteristic of well-constructed goals is that it addresses important issues. To maintain focus a business should operate with a limited number of major goals.
- A third characteristic of well-constructed goals is that they should be challenging but realistic.
- A fourth characteristic of well-constructed goals is that, when appropriate, they should specify a time period in which they should be achieved.

It is only logical that, once meaningful and well-constructed goals have been formulated and communicated to the stakeholders, a "road map" or strategy should be formulated to guide the business in the right direction in order for it to achieve its goals.

Taking into consideration that the business operates in an ever-changing environment, it would not make sense for the business to have rigid and stern goals. Should the environmental changes influence the business in such a way that the goals become unrelated to the mission, it should be possible for the business to correlate the goals accordingly to comply with the mission again. The third part of the strategy identified by Irons above motivates this argument.

Developing adaptable goals could be challenging and calls for creative and innovative strategic management.

Innovation and creativity

"The path to value innovation requires a different competitive mind-set and systematic way of looking for opportunities" (Harvard Business School Publishing Corporation, 2001: 1).

According to an article published in the Harvard Business Review, the authors assert that it could be detrimental to compete head to head with competitors during times when markets are flat or growing slowly (Kim & Mauborgne, 1999: 83). Kim and Mauborgne (1999: 83) are of the opinion that managers know instinctively during flat periods that the only way they can break free from the competition is to be innovative. The problem, according to Kim and Mauborgne (1999: 83), is that managers often do not know how to implement innovation, or where to start.

Incremental improvements in cost or quality or both are often the sole basis for rivals who try to outdo one another when they end up competing (Kim & Mauborgne, 1999: 83).

Strategic decisions and implementation

Hill and Jones (1998: 347) remark that strategic implementation refers to arranging the business structure in a way which will allow the business to pursue its strategy most effectively. This means that strategy should be implemented through organisational design.

Stewart, et al. (2005: 412) concur with Hill and Jones (1998: 347) and mention that the structure of the business should be adapted to the strategic plan, assuming a certain environment. Should the environment change, so should the strategic plan and the business structure. The strategy thus drives the structure.

Pearce and Robinson (2000: 357), state that managers should carefully translate the strategy into implemented actions. Pearce and Robinson (2000: 357) are in agreement with Hill and Jones (1998: 347) maintaining that the strategic actions should be coordinated and motivated by means of initiating four interrelated steps.

Once a business has its vision, mission and goals in place and has altered the structure of the business for strategic implementation, the business has to manage its strategy

STRATEGIC LEADERSHIP

Pearce and Robinson (2000:416) are unambiguous that management and leadership are two separate elements. Management is accordingly identified with skills and leadership with style.

Organisational leadership, according to the abovementioned, involves two considerations; the first, strategic leadership and the other, management skill. An enormous amount has been written about leadership and it is beyond the scope of this study to review this complex topic in detail. It could however be important to note that leadership should be seen as an important element of strategic management.

ENVIRONMENTAL ENVIRONMENT

Possibly the two most important dimensions in any business are external and internal analysis. Any business should be in control of its internal environment (resources and capabilities) but it is understandable that it is very difficult for any business to be in control of its external environment.

External environmental analysis

Grant (2010: 12) views strategy as the link between any business and the business environment. Strategy management, then, is to determine how the business deploys its resources within its environment to satisfy its long-term goals and furthermore, how to organise itself to implement that strategy.

Quantity surveying practices could apply strategy management principles to position themselves favourably towards their target market and could, by doing that, outsmart competitors.

Grant (2010: 122) mentions that strategy is concerned with matching a business's resources and capabilities to the opportunities that arise in the external environment.

Considering the risks and opportunities in the external environment, management must be informed of current and possible future circumstances. Once management is

confident of their comprehension of the external environment they might reflect on the internal business environment to adapt to the external environment for optimum profit.

Internal environmental analysis

Key internal factors could be a business's basic capabilities, limitations, and characteristics. Most businesses organise their operations at some level along functional lines to get their products and services produced, delivered, financed, and accounted. It stands to reason that close scrutiny of each of these functions serves as a compelling, strategically relevant focus for internal analysis. Analysis of past trends in a business's sales, costs, and profitability could be of major importance in identifying its strategic internal factors. This identification should be based on a clear picture of the nature of the business/practices' performance (Pearce & Robinson, 2000: 205).

ETHICS

The definition of "ethics" has come a long way from Aristotle's book "Ethics", which describes the goodness and virtue of mankind. Essentially, ethics could be described as "doing the right things". But why should businesses and strategic managers concern themselves with doing the right things?

Hill and Jones (1998: 59) maintain that any strategic action taken by a business inevitably affects the welfare of its stakeholders, namely employees, clients, stockholders, local communities and the general public. Pettinger (2004: 314) supports the view that ethics is the result of a fully considered view of the relationship between the business and its environment and all points of contact and interaction between them.

Immanuel Kant (1724 – 1804) the philosopher, argued however that the intention with which an action is performed is more important than the action itself (Law, 2007: 103).

EMPIRICAL STUDY

A pre-empted quantity of 70 questionnaires was distributed of which 48 respondents successfully replied within the allowed window period of 30 days. A success response rate of 68.5% was achieved.

The questionnaire first defined the term "strategic management" for unambiguousness and then challenged the respondent to value his/her opinion with regard to the different dimensions as identified above.

Table 1 lists the different dimensions with the average of each dimension divided by 5. The percentages in the last column indicate the respondents' approval with the dimensions. Higher percentages indicate a stronger feeling towards the importance of the dimension and visa versa.

Table 1: Strategic management: Averages

[D]	STRATEGIC MANAGEMENT	AVERAGE FROM 48 RESPONDENTS	
i.	Developing a Strategy	4.10 / 5	82%
ii.	Environmental Analysis	3.70 / 5	74%
iii.	Leadership	4.50 / 5	90%
iv.	Ethics	4.60 / 5	92%
AVERAGE		**4.23 / 5**	**85%**

Source: Own table compiled from returned questionnaires.

From the table it is clear that the majority of the respondents felt that the last dimension "iv. Ethics" is very important with a high favourable percentage of 92%. The dimension with the lowest percentage is "ii. Environmental Analysis" with a favourable percentage of 74%.

Question d4 in the questionnaire is a "balancing" question. The main purpose of the question was to test the respondents' understanding of the preceding questions as well as to finally weight the validity of the proposed pillar. The respondents were of the opinion that "Strategic Management" should be one of the maturity pillars of a quantity surveying business with an average response of 3.60 out of 5. That is a favourable average percentage of 72%. The following graph shows the difference between the averages of questions d1 and d4. The averages of question d1 were calculated in table 9.7 with an overall favourable average percentage of 85%.

CONCLUSION

Through environmental analysis, opportunities and threats could be identified. When opportunities arise a business could take advantage of those conditions to formulate and implement strategies that enable it to earn higher profits. Threats arise when conditions in the external environment endanger the integrity and profitability of the business's business. Adequate strategic management could increase the maturity of a quantity surveying business. Without any strategic management a quantity surveying business could face the danger of cessation. Strategic management is therefore regarded as one of the pillars of a mature quantity surveying business in South Africa.

Figure 1 illustrates the different dimensions of the strategic management pillar as identified in this paper.

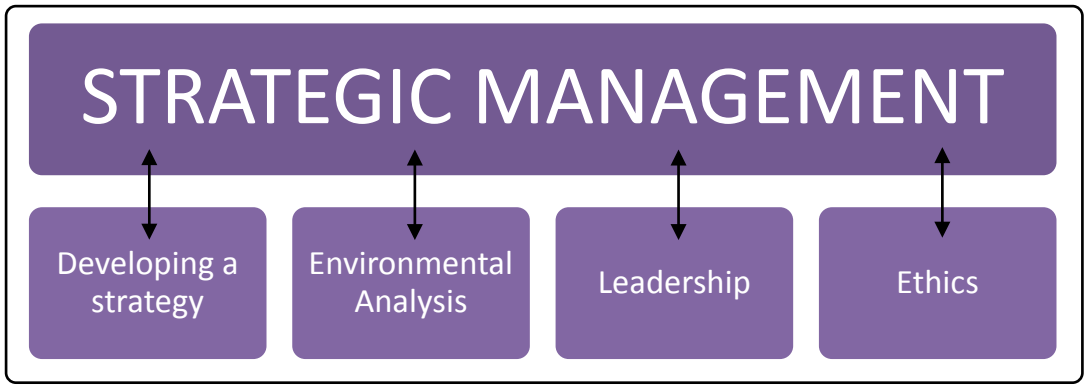

Figure 1: Dimensions of strategic management.
Source: Own table compiled from literature research.

The empirical study supports the literature research which indicates that most quantity surveyors agree that the proposed pillar "Strategic Management" should be regarded as one of the pillars for a hypothetical mature quantity surveying business.

The results from the maturity model could be valuable for the business which is benchmarking itself against the model for the following reasons:

- Areas of strengths and weakness could be highlighted;
- Growth could be scientifically measured;
- Growth could be measured against previous results; and
- Business values (share prices) could be compared to their maturity.

The results could also be valuable for:

- Academic institutions;
- Stocks exchange;
- Government; and
- The Public.

The quantity surveying business maturity profile could be a visual reflection of strengths and weaknesses and could guide businesses towards maturity.
"It is not the strongest- or the most intelligent ones' that survives but the ones' most adaptable to change." Charls Darwin (www.brainyquotes.com; online)

A REVIEW AND CASE STUDY OF INTEROPERABILITY WITH BUILDING INFORMATION MODELING AND FACILITY MANAGEMENT PROCESSES

Anthony J. Perrenoud[1], Kenneth T. Sullivan[2]

[1,2]*Arizona State University, PO Box 870204, Tempe, AZ 85287-0204, USA*

ABSTRACT

The average lifecycle of a building is seventy years, during this time the majority of investment is dedicated to operating and maintaining the building. The information that is developed and collected in the design and the construction of a building is uniquely important to the team that maintains and operates the facility. The information used for operation and maintenance is often times inadequately stored which creates an ineffective, costly, and unorganized information system. Every year in the U.S. an estimated 15.8 billion dollars is lost from the inadequate interoperability of systems within the building lifecycle. With the developments in technology, building information modeling produces greater interoperability of information from the designer and the constructor but continues to be ineffective to the facility management team. The lack of cost effective systems that connect the building information models to the facility management software continue to deny building operators access to the information contained in the building models. This paper includes a review of the industries inefficiency to maximize interoperability throughout the building life cycle, also included is a case study of an owners method to access the information within the building models developed during the design and construction of the building.

Keywords: Building Information Modeling, Facility Management, Interoperability, Operation and Maintenance.

INTRODUCTION

An effective supply chain includes proficient exchange of information, materials, money, manpower, and capital equipment between all parties (Mentzer et al., 2001). A building life cycle includes many disjointed groups within its supply chain; information must transfer between these groups. Designers must transfer countless specifications of the design to the contractors, which then must pass this information on to the operators who maintain the facility. This supply chain is stretched over a seventy year time period (Gallaher et al., 2004; Kelso, 2011), which is why the procedures to manage building information is so unique. With every transition between building controllers, information is diluted and the ability to manage the building effectively decreases. Every year billions

[1] aperreno@asu.edu
[2] kenneth.sullivan@asu.edu

of dollars are lost in the United States from inefficient procedures managing building information (Gallaher et al., 2004).

Owners and operators can establish the procedures to manage information more efficiently. A productive information management process should be capable of sharing building information with all building operators involved in the life cycle. It should also allow users to create, exchange, analyze, and update information (Smith & Tardif, 2009). The goal of every building owner and operator should be to improve the supply chain and implement the most efficient information technologies to reduce wasted time and resources (Dennis, 2003). Building Information Modeling (BIM) technology has recently increased efficiency of the design and construction of buildings. However, financial benefits with BIM are still unclear with owners and building managers with regards to operations and maintenances (O&M). This paper will review the need for better information exchange throughout the building life cycle focusing on the O&M phase and present a case study on one of the ten largest children's hospital in the United States attempts to improve the process of managing their building information.

Building Life Cycle

A thirty-year life-cycle cost assessment sponsored by the U.S. Department of Energy (see figure 1) states that 2% of the life-cycle cost for a building is due to design and construction, 6% is from operations and maintenance, and the majority 92% is due from the salaries of the personnel that work within the building (Kelso, 2011). With a majority of the cost going to those that are employed within the building, organization leaders will be more focused on employees and less focused on the building itself. The smallest portion of designing and constructing the building greatly impacts the costs related to operating and maintaining the building.

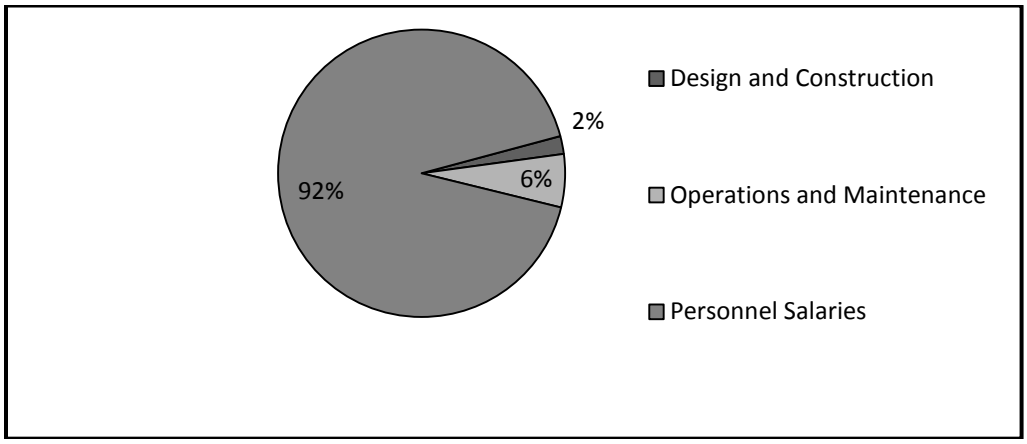

Figure 1: Building Life Cycle Cost Assessment over a 30 year period

Cost savings planned and implemented during the design phase focuses on improving the building efficiency, by lowering maintenance and operation costs in the initial phases owners will have a greater return on investment (Rondeau et al., 1995; Jensen et al., 2009; Thomas, 2010). Unfortunately, building design is mainly focused on the initial capital

investment of the property as many designers hold little responsibility for the financial impact that is included with operating and maintaining the building (Smith, & Tardif, 2009). A mistake found in many construction projects is miscommunication between the design and facility management team while designing a more efficient building to operate. It is the responsibility of the facility manager to be included in the design phases of the building to ensure that owner's best interests are included to maintain their future building (Jensen et al., 2009). The breakdown of communication between the design, construction, and operators is a large area that has resulted in wasted time and money for the owner (Snitkin, 2009).

Inadequate Interoperability

The lost cost due to the inability to exchange information to building managers throughout the building life was captured in a study done by the National Institute of Standards and Technology (NIST) in 2004. The report explored the information interoperability with the facility supply chain. Interoperability can be defined as the ability to transfer, comprehend and utilize information from one system to another. The report estimated 15.8 billion dollars is lost annually in the U.S. through inadequate interoperability. The research focused only on documented loss, which is why the 15.8 billion is considered to be an underestimate of the actual lost capital (Gallaher et al., 2004). The largest area of lost cost is found within operating and maintaining the building, nine billion dollars annually or 57 percent. Table 1 breaks down the O&M lost costs from the NIST report.

Cost Component	**Inadequate Interoperability cost estimate**
Inefficient business process management costs	$1,638,915,000
Redundant facilities management system costs	$456,064,000
Productivity loss and training costs on redundant facility systems	$12,615,000
Redundant facilities management system IT support staffing costs	$10,701,000
Interoperability research and development expenditures	$1,659,000
O&M staff productivity loss	$613,310,000
O&M staff rework loss	$3,952,000
O&M information verification costs	$4,790,159,000
Idled employee costs	$1,499,839,000
TOTAL	$9,027,214,000

Table 1 Lost Cost due to Interoperability found with Operation and Maintenance

The largest four contributions to inadequate interoperability seen from the information passed to the building operators:

1. *O&M information verification cost*

   The majority of organizations do not have a structured handover practice which leads to facility managers verifying that the information handed over is correct and represents the current state of the building. Experienced facility managers have empirical knowledge of the building, but when staff is replaced through retirement

or replacement the information is lost with the knowledge of the departing employee (Smith, & Tardif, 2009).

2. *Inefficient business management cost*

   A study on the efficiency of exchange through different means of communication found paper to lead to the greatest waste in time of information exchange. The study also found that electronic formats can reduce the time necessary to exchange information by 28 to 59 percent (East & Love, 2011). Seventy to ninety percent of the information exchanged in the life-cycle of the building is in a paper format (Gallaher et al., 2004).

   Inadequate information is often the root cause of environmental and safety cost impacts; poor information can lead to incorrect maintenance, overused equipment, unsafe maintenance procedures, or premature replacement (Snitkin, & Mick, 2010).

3. *Idled employee costs*

   Studies have shown that O&M staff will waste up to 40 percent of their time by searching unorganized and inaccurate information (Snitkin, & Mick, 2010).

4. *O&M staff productivity loss*

   If the information lacks validity or is missing O&M staff will lose confidence in the business structure, and the information that it contains. As-built documents in particular, should represent the current state of the facility that can be analyzed by the staff and allow edits and updatse to assist future renovations. Surveys of facility managers within the U.S. Army and in the private sector have shown that most as-built documents are not accurate and difficult to find (Clayton et al., 1999).

The NIST report concluded that owners can minimize the lost cost with improved technologies that link information developed during design, construction, and O&M into one information management system. The current build industries continue to promote Building Information Modeling (BIM) as the technology that will minimize the lost cost of inadequate interoperability. By improving the way in which information is passed from designer and constructors to the owners, it eliminates the need for boxes of construction documents, warranty's, and invoice documents to be passed to owners after the completion of the building. It will also eliminate the necessity of facility management departments to reassess the completed building to update as-builts from the construction period (East, 2007).

Facility Management Struggles with BIM

Relevantly new to the facility management industry, BIM records valuable information on the building systems and materials collected during design and construction of the

 ISBN: 978-1-84219-840-7 .

building. BIM provides great potential to improve interoperability to FM information management processes and is promoted continuously to the facility management industry.

The reason that BIM has not developed largely in the facility management industry is due to the reasonableness and return on investment of the product. In a 2008 survey, facility managers found the top five reasons operators will not invest in BIM (Forns-Samso, 2008):

1. Unwilling to change process – the majority of existing buildings are going to have a method of maintenance, data storage, and building drawings. A large ROI would be required for a facility to change their traditional way of operating;
2. Funding/cost - the cost of creating a BIM model on an existing building greatly outweighs the current abilities that 3D models assist facility managers. An estimated cost of creating a BIM department within an organization is $100,000 to $120,000 (Hardin, 2009). Often time's facility budgets are too limited to maintain the building properly, the percentage of facilities that have the extra capital to invest in digital models is very small;
3. Lack of understanding – understanding the benefits of BIM in facility management is still being researched. Facility managers that have not been introduced to 3D modeling do not understand why 3D would benefit their operations;
4. Lack of personnel and resources - most software's that are available to facility managers are not compatible with puling data from the 3D models that are produced in design and construction. The very small exceptions of software that have begun to include 3D models are still primitive in their development;
5. Data updating/ maintenance – once a model is handed over to the facility managers; various products are required to maintain the model. The numerous building systems in a structure require different software for updating. Software that can edit and navigate the entire model still does not exist. If the owner invests in the cost of the technology required they will also need to pay for an in-house BIM manager to maintain their software consistently.

Although the issues related with BIM and facility management are prevalent the pace of technology and education continue to work to link the two. Many government agencies and private business have begun to require 3D models with the handover of their buildings (BIM Initiatives, 2010). Government agencies, research developers, software designers, and facility managers are investigating how they will propel the facility industry into the benefits of BIM.

CASE STUDY

Background

In an attempt to minimize the lost information during the building life cycle and to incorporate BIM into facility management a team of designers, contractors, and operators of a hospital facility developed an electronic information exchange for the new addition of their existing facility. The Phoenix Children's Hospital (PCH) in Arizona is one of the largest children's hospitals in the United States. To manage the growing population in the

Phoenix area the hospital expanded its facilities by 770,000 square feet in 2008. The project included additions to existing hospital facilities that would continue to operate, which required preplanning to ensure that the construction would not disturb the hospital operations. With the safety hazards and the complex building systems, the designers and contractors recommended that BIM model should be used to minimize risk with the project. PCH recognized the benefits of the BIM model and required that it would be handed over to their facility management organization so that they would be able to incorporate the models into maintaining the facility. Their experience with incorporating information from BIM models is a recent case study for the construction industry's ability to exchange information electronically to the operators.

Development

Although existing procedures were established to maintain their building information, the operators were willing to change their processes to fit the outcomes with the 3D models. Laser scanning was performed on the existing facilities so the new 3D models would align to the buildings. The construction company contracted was very proactive with the facility management team on getting them involved with the construction of the facility and persisted to ensure that FM team would have the information needed to operate the building. The design, construction, and FM teams would have weekly meetings in which they could collaborate on the construction of the building and determine what information would be needed for maintenance after completion of construction. The information that the FM team would need was recorded and was linked to an asset-management tool that would be handed over to the O&M team. As the project progressed, as-builts of the construction were updated in the model to ensure that the model was completely accurate to what was constructed. Looking back at the collaboration that was managed during the construction the facility director would have liked to start this same level of collaboration earlier in the design phases of the building (Laster, 2011).

Handover

As the project neared completion, the information that was developed in the model was linked to an asset-management tool that was an online interactive tool developed by the contractor. The handover of information occurred over many months and multiple versions to ensure that all building information was included. The final proprietary tool provided by the contractor is a web-based instrument panel that allows facility management to locate information quickly on the building. The facility team can locate building information with a few clicks of the mouse to access information that previously was stored in poorly organized boxes. The asset-management tool links to equipment data, service manuals, equipment performance, warranty, manufacturer contacts, and video. The video contained the installation and maintenance procedures and are available for technicians to review before maintenance.

The asset-management tool is also linked to the BIM models in which operators can quickly pull up 3D models of the building, complicated systems within the building, and 2D layouts of areas in the building. The 3D models are linked to Autodesk Naviswork, which allows viewing of the 3D models and is linked to the stored information on the different systems within the building. The cost of the software was included in the contract

and allowed the facility team to view the 3D models on select stations (Laster, 2011). Although no extensive training is needed for Naviswork, it does not allow the operators to update the model when reconstruction of the building occurs. This is one of the limitations of the system it is also unable to link directly to the operator's computerized maintenance management systems, which manage the maintenance work of the facility.

CONCLUSION

In conclusion, billions of dollars are lost yearly from the inability to pass building information effectively from design and construction to the owners and operators. Future technology should continue to develop the ability for information to be passed down throughout the building life cycle. Even with the many benefits of BIM in the construction of buildings, facility managers still have many reasons not to invest in BIM models. The presented case study demonstrates one method that is currently available to facility managers to receive an electronic information exchange through a web based interactive tool. Many limitations still exist with this method of utilizing the information in the BIM models, but the industry is showing progress towards incorporating the information rich 3D models into facility management.

ICT IN SITE MANAGEMENT PROCESS IN SOUTH AFRICA

Aghaegbuna Ozumba[1] and Winston Shakantu[2]

[1]*School of Construction Economics and Management, EBE Faculty, University of the Witwatersrand, Johannesburg 2050, South Africa.*

[2] *Department of Construction Management, EBEIT Faculty, Nelson Mandela Metropolitan University, Port Elizabeth, South Africa.*

ABSTRACT

Integration of Information and Communication Technology in the Site Management Process; is the topic of interest in the paper. With focus on the South African construction industry, results of a pilot study investigating integration of ICT in the Site Management Process are presented. Review of purposively sampled literature, complimented by survey on a limited sample; is used to generate contextual deductions. The paper is part of a wider research agenda in Construction ICT. However findings from the pilot study suggest considerable lack of awareness, familiarity, and utilization of available ICT-based products (software, hardware and technologies) by practitioners. In addition there seems to be a negative correlation between familiarity with technologies, their usage and depth of utilisation at work.

Keywords: adoption, ICT, innovation diffusion, SMP, technology transfer.

INTRODUCTION

The construction industry is an influential economic sector, which utilises human, material and financial resources. Construction activities are labour and capital intensive, providing favourable ground for economic empowerment (Thwala, 2005). Presently the construction industry has become a global arena. Complexity and competitiveness have increased with influx of global participants in projects (Liu & Erickson, 2002; Sarshar & Isikdag, 2004). Fundamental changes across old professional categories, and project teams were noted by the 1990s (Howard, 1998). The worldwide growth of construction industry is evident in the adoption of technological and scientific innovations (Haas & Saidi, 2005; Shakantu & Kajimo-Shakantu, 2006). Despite dividends from various adopted innovations, the need for more technology integration remains a challenge to construction (Flanagan et al., 2001). Modern construction is complex and has physical realities, which point to a need for more technology such as Information and Communication Technology (ICT). Such needs of the contemporary construction site are evident in the Site Management Process (SMP) (Fuller & Sattineni, 2002; Cabarello, 2002). Growth of

[1] obinna.ozumba@wits.ac.za
[2] winston.shakantu@nmmu.ac.za

ICT presents more opportunities for ICT integration in construction. However the construction industry is regarded as lagging behind in the adoption of ICT despite perceived advantages (Shakantu & Kajimo-Shakantu, 2006). Utilisation of ICT in construction does not take full advantage of potential uses (Haas & Saidi, 2005). Barriers to success in this regard especially for the SMP point towards the need for a different approach to ICT implementation. There have been calls for more innovation in the adoption of ICT in construction. It has also been emphasised that such approaches should work from a sound knowledge of the construction environment, its participants, and developments in ICT (Ugwu & Kumaraswamy, 2007).

The background and needs highlighted above informed the design of a postgraduate research project. The main aim was to investigate integration of information and communication technology, in the South African construction industry; using the SMP as context. Work presented in the paper is an excerpt from preliminary studies carried out during the degree project; under the banner of Construction Information and Communication Technology (CICT).

CONCEPTUAL AND THEORETICAL BASIS FOR THE STUDY

ICT utilisation in the SMP as presented here concerns the following main concepts: Technology transfer, innovation, adoption and diffusion. The study investigates the intersection of these concepts in the context of ICT, the SMP and the South African construction industry.

Innovation

Innovation has been defined as the successful exploitation of an idea in a new unit of adoption (Egbu, 2001 in Fryer, Egbu, Ellis and Gorse, 2004). From a management point of view, innovation is described as the heart of entrepreneurship or entrepreneurial activity which inspires enterprise wide, economic and social change (Drucker, 1998). From a construction perspective innovation can also be described as a new concept which is adopted by a client in a construction project. The aim would be to derive increased benefits through returns on investment (Ling, Hartman, Kumaraswamy and Dulaimi, 2007). Innovations, especially the technological kind, go through creation and diffusion stages in their life cycle (McGinn, 1991: 80-81).

Diffusion

Diffusion involves dispersion or physical movement of substance. ‘Substance’ here could be anyone of a broad range of things, subjects, objects, and information among others (Morales and Gilner, 2010). Rogers and Shoemaker (1971) identified eight scholarly traditions of diffusion. The relevant tradition here is diffusion of innovations. It is defined as a communication process through channels, by which an innovation is communicated to the units / members of a social system (Rogers and Shoemaker, 1971). Diffusion of innovations rests on adoption and time frame of adoption of each innovation within a particular setting. Adoption occurs when a party decides and acts upon the decision to employ or utilise an innovation. The time lapse between the first cognitive interaction of the innovation and the final adoption becomes the time frame of innovation diffusion (Rogers, 2003).

 ISBN: 978-1-84219-840-7 .

Technology transfer
Similarly, Technology transfer could be described as movement of technology to various other contexts; by communicating and adapting the innovation to each context (International Council of Scientific Unions (ICSU) and Committee on Science and Technology in Developing Countries (COSTED), 1980: 159). Technology Transfer is also described as the spread and adoption of inventions and techniques from one discipline to another, and from one sector to another (Parker, 2010). Thus technology transfer embodies the essence of innovation, diffusion and adoption.

The Site Management Process (SMP) and need for ICT
Within the focus of study, relevant concepts relate to the diffusion and adoption of technological innovations of ICT in the SMP, as a consequence of technology transfer. The SMP is a complex field, involving planning and continuous application of various management functions, on site throughout the construction phase (Forster, 1995). The ad hoc nature of construction projects encourages the use of matrix organisational structure in site management (Kuprenas, 2002; Hendrickson, 2003). However the site remains a highly volatile environment which could erupt in many issues that affect its management in various ways (Forster, 1995). Increases in project complexity and volume of stakeholders, expectedly stretches site management capacity. Increased strain on process management would translate to project delivery problems, which influence client satisfaction (Ozumba & Shakantu, 2008a). The consequence would be sub-optimal levels of performance. In addition, human limitations create practical management capacity issues such as ubiquity, which plagues management of construction site processes (Ozumba & Shakantu, 2008b).

The scenario above is more evident with current global developments which have made the industry more accessible, especially in developing countries (Ozumba and Shakantu, 2008a). The above mentioned situations are particularly true in emerging economies such as South Africa. Causative factors include the multiplying effects of socio-economic and political realities in so called ‘developing countries’. As shown in (Ofori, 2000), the construction industry in developing countries faces the double impacts of globalisation and culture, and the desperate need for physical development. Management of projects is bound to become even more critical under such circumstances. Thus there is appreciable need for efficient site management in the setting described. The stated need for process enhancement could be achieved through employment of technology such as ICT and related types (Ozumba & Shakantu, 2008a). On the strength of concepts reviewed, the study concentrates on transfer of ICT in the South African construction industry. The SMP is used as context. Therefore investigations are focused on management level practitioners within the SMP.

METHODOLOGY

The study presented here is part of a postgraduate degree project; performed as part of initial studies in the data collection stage. The overall methodology utilised a combined approach which included survey by questionnaire. Data analysed for the paper was collected using survey method (Creswell, 2003).

The pilot survey was limited to practitioners within the Gauteng region of South Africa which is the business centre of the country. Essentially, the Greater Johannesburg area was used. Participants included construction managers and project managers and all who are involved in the construction site processes, at management level. They were essentially people in middle and first line management, and supervisory levels on construction projects. Data for the study was collected in 2011. The time frame covered in the questionnaire was (2008 – 2011). Participants responded to questions fielded for a range of ICT products, technologies and services; numbering 27 in all. Items of ICT studied were grouped into 5 categories namely: Mobile / handheld devices, Geographic and surveillance systems; Sensors and scanners, Hybrid technologies (BIM, Telepresence etc.), and wireless applications and services.

The following constructs were developed for the pilot study: Familiarity with the ICT; ICT usage within time frame of study; ICT utilisation in project stages; physical areas of utilisation; specific site management work of ICT utilisation; and product features utilisation. The pilot study at this stage was basically exploratory. However the questionnaire was largely structured, to reduce ambiguity and misinterpretation. Questionnaires were administered twice in sequence, targeting members of two professional bodies in the built environment. All together 15 practitioners participated in the pilot study. Questionnaires were distributed electronically, in excel and PDF versions. All 15 completed questionnaires were then analysed. Respondents cut across various core disciplines in the construction industry, and have all been involved in the site management process. Such purposive sampling was deemed adequate for the pilot stage of the study. Descriptive analysis was also used at this stage; considering the purpose and sample. Analysis and findings are presented according to the constructs explored. At this stage, the analysis leads to suggestions through which propositions were formed for the main research work.

SUMMARY OF ANALYSIS AND FINDINGS

For the purpose of the paper, analysis and findings are summarised. A binary mode was used for data entry where (yes = 1, and no = 0). For practicality values in each case were added up for all 27 items of ICT. Expected values for each construct were calculated and used to evaluate values derived from responses. Thus a first attempt at painting a picture of the situation on ground was made. Using the sample of 15 respondents, results are presented as approximate proportions of expected values, and also proportions of the sample. For a sample size of 15 and possible observations of "YES" for 27 items of ICT, highest possible value of observations is 405 = (15 x 27). Highest observable sample mean is 15 = (405 / 27). Similarly by proportion, 405 represents 100% (highest possible observation value). Thus any observation falling below 405 is calculated as a percentage of 405.

For familiarity with the product, expected value is 405 while response was scored 251, making it approximately 61%. Under time span of usage (2008 – 2011), respondents scored very low at 23% (375 out of 1620 of expected value). ICT utilisation in project stages concentrated on utilisation during the site or construction phase of projects. For this construct respondents scored low at 31% of expected value

(405). Product features utilisation queried the depth of usage of the features incorporated in each item of ICT, among respondents. The score was similarly low, at 28% of expected value (405).

For site management work of ICT utilisation, the aim was to ascertain the exact function performed with the aid of ICT on site. It is then possible to group various functions indicated, in order to get a picture of major types of usage. Responses were fairly grouped into 6 categories namely: health and safety, access control and security; laser measurements, and identification of hidden objects and lines; site administration, supervision and labour management; logistics and control of materials and equipment; site and project level communication, and information management; and project location verification, setting out and topographic surveys. Of all the above mentioned, general administration of the site was the most indicated. Communication was also equally indicated, but referred mostly to phone calls and the use of emails.

Other highlights include the self-assessment for utilisation of product features. For the purpose of analysing this section, ICT investigated were grouped into 5 categories: Mobile / handheld devices, Geographic and surveillance systems; Sensors and scanners, Hybrid technologies (BIM, Telepresence etc.), and wireless applications and services. Most respondents indicated very high utilisation of mobile/handheld devices. However some of the hybrid technologies and wireless services were not utilised.

DISCUSSION

Generally, usage of the range of ICT in the study was quite low or non-existent in most cases. Response about specific areas of utilisation suggests minimal usage recent ICT in the SMP, during the construction phase, and on site. At best responses suggest very little innovative usage of ICT. They seem to be used for specific purposes though some of the items are versatile in terms of capacity. Furthermore majority of respondents did not indicate familiarity with all items studied, especially some more recent items in the hybrid technologies category. Hence the seeming awareness of ICT among participants, does not translate to commensurate working knowledge and utilisation. The contrast between awareness of ICT and its usage suggests the occurrence of a much larger innovation adoption time frame. The suggestion is further supported by the rate of utilisation observed within the time frame of research.

CONCLUSION

As stated earlier, the study forms part of preliminary work in the course of a post graduate degree. Thus delimitations of time, scope and sampling were placed on it. A larger sample size could be accessed at the time of the pilot study. However it was designed to further clarify directions and adjust the inquiry for the degree project. As such it is possible to draw directions for a more representative research. Therefore only suggestions were made at this juncture. The suggestions have been used to formulate propositions guiding the main research project. They are presented below as possible implications.

Analysis of the survey response suggests that people in the sample population may be poorly exposed to relevant developments in ICT and allied industries. Secondly it seems that utilisation of ICT in the specific context of the study, is limited to pre-set capabilities / features that can be easily grasped. Thirdly, there seems not be much innovation in the usage of items of ICT studied. Fourthly there seems to be very poor awareness of possibilities in ICT such as virtual reality, augmented reality, Telepresence and Building Information Modelling, among others. Such low levels of awareness would negatively affect useful exploitation of recent ICT in the SMP, and other aspects of construction. The last point speaks to management issues surrounding ICT utilisation in construction generally. Much of the awareness indicated does not seem to translate into utilisation. It is possible that management does not provide for such technologies in projects. Another reason could be that respondents were involved in projects which were deemed not to require such technologies. Both of these reasons proffered here would be partly as a result of poor information and probably poor innovativeness.

Generally issues highlighted point towards the need for further investigations. There is also the contextual issue which could be a strong influence on the use of ICT in construction, in this particular case. There could be ICT utilisation specific peculiarities to be found amongst the management class of construction practitioners in South Africa. The representativeness of ICT manufacturers and their products, in South Africa and its construction industry could be a major factor. A key question developing from the findings concerns the mind-set; at industry, corporate, project and individual levels, of interaction with various types of technology. In furthering the study it is necessary to consider diffusion patterns of successfully adopted technologies in construction. It could be insightful also to understand what peculiar factors if any, influence the diffusion process for ICT and related technologies, within the SMP in South Africa.

QUANTITATIVE ANALYSIS OF ICT UTILIZATION PROBLEMS IN THE IRANIAN CONSTRUCTION INDUSTRY

Ali Alaghbandrad[1] Ehsan Asnaashari[2] and Mohammad Bagher Nobakht[1]

[1]*Department of Construction Engineering and Management, Science and Research Branch, Islamic Azad University, Tehran, Iran*

[2]*School of Architecture, Design and the Built Environment, Nottingham Trent University, Nottingham, UK*

ABSTRACT

Fast development of computer, information and communication technology (ICT) has resulted many changes in using of information and knowledge in construction industry. Construction companies have used ICT because they believe that it increases efficiency and safety of their projects and give them the power to compete in the market. In Iran, construction firms have utilized ICT tools in their projects for several years. However they have encountered some problems during adoption of ICT. This research identified some of these problems through a set of interviews with highly experienced construction practitioners and software providers. To determine the severity of each problem, a questionnaire was developed and distributed among senior managers and experts of five civil organizations and construction associations. The returned questionnaires were analyzed quantitatively and the problems were ranked based on their importance. Weak ICT infrastructure, low speed internet and shortage of ICT training to construction practitioners are the three main problems of ICT adoption in the Iranian construction industry.

Keywords: construction projects, ICT, Iran, quantitative analysis.

INTRODUCTION

Information and communication technology include a wide rang of software and hardware and communication tools which can facilitate the heavy calculations, visualization and design process of construction projects. Construction firms have utilized ICT tools to reduce the cost and time of their projects and make much benefit from their works. Effective communication will help managers make on time decision and better manage the project by having updated information and fast communication with other parties. Information are saved and kept in electronic formats so fast and easy access to data is possible by new documentation and archive systems.

[1] a.alaghbandrad@srbiau.ac.ir
[2] ehsan.asnaashari@ntu.ac.uk

In the recent years, Iranian construction companies have increased using of ICT. However, they have encountered with some problems and barriers to adopt ICT in their projects (Alaghbandrad et al. 2011). To overcome these problems, at the first step, they should be identified and categorized carefully, then, be ranked based on their severity. This research aims to quantitatively analyse the ICT utilization problems in the Iranian construction industry.

PREVIOUS RESEARCH

The great values that ICT can bring for construction industry are emphasized in many researches which were conducted in different countries: peansupap et al. (2006), Williams et al. (2007), Hewage et al. (2008), Kaplinski (2008), Adejimi (2009), Ahuja et al. (2009), Isikdag et al. (2009), Abdul Kareem et al. (2011), Underwood and Khosrowshahi (2012).

Abdul Kareem et al. (2011) found some benefits of implementing Information Technology (IT) in construction projects in Malaysia such as client satisfaction, cost reduction, improving management, competitiveness advantages, improving information quality, increasing work flexibility and reducing working time. They also noted some problems of IT adoption process in Malaysian construction industry such as insufficient bandwidth, lack of training and unavailability of expert users in construction companies.

Through a research in India, Ahuja et al. (2009) understood that for SMEs (Small and Medium Enterprises) initial cost and cost of updating IT infrastructure are important barriers for ICT adoption in building projects. Ahuja et al. (2009) recommended that ICT capabilities of SMEs need to be improved by providing education and training facilities for staff members. SMEs should make strategic plan for future use of ICT in their companies.

In Turkey, Isikdag et al. (2009) conducted a series of semi-structured interview with contractors and consultants to investigate three points, 1- the role of ICT strategy in organizations, 2- reasons of investments in ICT and 3- barriers to successful implementation of ICT in organizations. Ill-defined process is explained as a major barrier.

In Alberta, Canada, Hewage et al. (2008) revealed that the managers are worried about skills of workers in construction sites if IT becomes a part of work place. The managers expressed that they have experienced resistance of older workers whenever a new technology is adopted. Lack of industry-wide standard, lack of manager interest on IT, lack of funding, lack of knowledgeable people for new innovation, unclear needs and human issues are the main issues of technology providers in Alberta.

In his research, Kaplinski (2008) indicated that expenditure and investment in IT tools in construction sector is insufficient in poland.

Based on the findings of Peansupap et al. (2006) study, constraints of ICT implementation in the Australian construction industry at the personal level include limited budget for ICT investment, commitment from other project participants, issues of ICT standardisation, and security problems. At the organisational level, constraints include basic levels computer experience, time available to learn, and the identification of clear benefits of ICT use. Constraints at the group level include time available to share information, quality of personal contact and geographical distance.

Williams et al. (2007) research indicated that reluctance by project participants to share data and information is the most important barrier of using of web-based IT in the U.S. Need for training, high cost of implementation and little return on investment are other important barriers.

Underwood and Khosrowshahi (2012) stated that the majority of organisations in the UK intended to 'flat-line' or reduce ICT operating budgets in 2010 owing to the global economic crisis. They expected that this issue continues up to the point that organisations observe a sign of improvement in the economic condition.

ICT in Iran

Alaghbandrad et al. (2010) found that the Iranian construction firms invest in ICT tools based on their needs and functionality of the facility. Quality in ICT application is a key for construction organizations. However, investing wisely is a priority for the managers. The important parts of a typical automation system in Iranian construction companies are archiving, personnel management and communication.

Alaghbandrad et al. (2011) identified the most important factors which should be considered to transform problems to opportunities as following: infrastructure, cultural matters, training, regulations, user friendliness, financial issues and the lack of a common standard for ICT adoption among firms.

Alaghbandrad et al. (2012) understood that barriers and problems of ICT utilization in construction sites in Iran can be described in seven categories: poor ICT infrastructure, lack of local personnel familiar with ICT systems in remote construction sites, no economic justification for ICT training of personnel in small construction sites, lack of feeling transfer in some electronic communication tools (e.g. video conference), inapplicable software outputs, complicated administrative process for ICT development, and poor back up system in remote construction sites.

RESEARCH METHODOLOGY

Each research can benefit from different ways and tools. The literature review helps researchers to know the previous efforts in the research area. The interview is one of the data collecting methods. It helps the researcher benefit from experience, personal histories and perspectives of experts and experienced people (Bryman and Bell 2003). Selected sampling is the best sampling method for qualitative interviewing (Naoum 2007).

This paper is part of a broader research that benefits from interviews and questionnaire for collecting data. This paper presents results of quantitative analysis carried out on data collected from 55 questionnaires.

At the first phase of this research, twelve semi-structured interviews were conducted with highly experienced construction practitioners and senior managers in construction organizations and software providers. The interviewees were selected carefully from experienced experts and managers who were familiar with construction environment and ICT application in construction in Iran. During the interviews, the respondents were asked about the problems and barriers of ICT adoption in their firms. The interviews were continued up to the point that the responses were repeated and no new information were obtained from interviewees (data saturation). Then the interviews were qualitatively analyzed and the main problems were highlighted.

In the second phase of research, a questionnaire was developed and distributed among senior managers and experts of five civil organizations and associations to determine the severity of each problem. The filled questionnaires were analyzed quantitatively.

In the questionnaire, first, a brief definition and explanation about ICT and its application in construction was written. Then, the respondents were asked to answer some personal questions about their position in company, education and work experience. They were also asked about their knowledge of ICT application in construction, use of personal computer and access to internet in their work places. Then, they give their opinion about the situation of using ICT in their organizations. Finally, 14 main problems of ICT adoption in the Iranian construction industry were presented in a table and the respondents were asked to choose an option based on the severity of each problem and the options were scored based on Likert Scale as following: “very important=5”, ”important=4”, ”somewhat important=3”, “less important=2”, “non important=1”

This is a scale developed by Rensis Likert for measuring the degree to which people agree or disagree with a statement, usually on a 3-, 5-, or 7-point scale(Adejimi 2009).

After collecting the questionnaire, statistical analysis was started. Mean and standard deviation were calculated to better describe the results. The average score of respondents is indicated by “mean” and the “standard deviation” shows the variation from the mean. To facilitate the heavy volume of calculation, Statistical Package for Social Sciences (SPSS) software is employed. To rank the problems, each one was given a score. This score comes from the average (mean) of responses for severity of each problem.

Based on the obtained data, the education level of 55 respondents is: 1 person high school diploma, 24 people bachelor degree, 25 people master degree and 5 people PhD. The field of study of 29 respondents were civil engineering, 9 people architecture, 2 people management and the other 15 respondents miscellaneous. 17 people had work experience of 1-4 years, 3 people 5-9 years, 9 people 10-14 years and 27 respondents had more than 15 years of work experience. Based on the responses, 14.3% respondents stated that they are quite familiar with the ICT application in construction, 53.6% were familiar, 23.2% were somewhat familiar, 5.4% were less familiar and 3.6% were not familiar at all. All respondents had personal computer in their work place and all people except one who did not answer, had access to internet in their work place. 17.9% respondents chose “very much” as answer for appraisal of ICT application in their work place, 32.1% said “much”, 37.5% said “average”, 8.9% said “little”, 1.8% chose “very little” and 1.8% did not respond to this question.

DATA ANALYSIS

Data gathered from the interviews were qualitatively analysed. Based on the information obtained from the interviewees, the ICT utilization problems in the Iranian construction industry are categorized in 14 groups. To clarify the severity and importance of each problem, a questionnaire was developed and distributed to 55 senior managers and experts in Iranian construction industry. The data was quantitatively analysed.

Qualitative data analysis

During the interviews, the respondents were asked about the problems and barriers of ICT adoption in their firms. These problems are expressed in the following:

1-Weak ICT infrastructure: Most of the respondents believe that Iranian ICT infrastructure must be improved. The availability and quality of ICT in far-off lands in the country is very important because most construction and civil projects are located far from cities while the ICT is a vital need for these projects.

2-Shortage of ICT training to construction practitioners: Knowledge and skill in ICT is an important item for construction practitioners. Providing enough training for construction personnel within firms is a significant factor in success of ICT adoption in companies. The training courses must be tailored to real needs of each company.

3-Information security and confidentiality: Some of respondents were worried about security of information in the electronic format. They believed that storing data in electronic files increases the risk of information leakage from data storages. In fact, there is a lack of trust about security of information in electronic format.

4-Possibility of data loss: Information storages are vulnerable against events such as electricity fluctuation, hit damage and water penetration.

5-Lack of interest in using ICT tools among older construction practitioners: Some of construction practitioners avoid using new technologies and ICT tools in their work. They resist against the automation systems because they think that these new tools will do their duties and can make them unemployed. This attitude is much seen in elderly people. They also sometimes think that the ICT tools are not helping them in doing their job.

6-Lack of trust in output of construction softwares: Some of the respondents believed that the output of design and construction software is not as much precise as needed. The results may not be constructible in real world and cannot be trusted particularly when an unskilled designer is using the software.

7-Incompatible rules of construction industry with ICT: Most of the current rules of construction industry are formed in a world without ICT. They are not compatible with the needs of new technologies. For example, one of the respondents said that the electronic signature is not usually acceptable in administrative process of construction projects.

8-Shortage of user-friendly softwares: Making a user friendly graphic environment can encourage users to learn the software and use it more. A graphic environment which is similar to famous softwares (e.g. MS Word) can help the users how to work with the software easier and faster. Shortage of user friendly software can discourage construction practitioners to use them.

9-Poor support of ICT providers in construction industry: The support of ICT developers is an important factor which can encourage users to use their products more. Poor support can result in leaving new technology and returning to traditional methods in information and communication management in construction.

10-Low financial support of construction companies for investment in ICT: Investment in ICT is a critical problem in some of construction companies in Iran. In some cases, the firms are not in a stable financial status. They cannot be sure of their expected profit. As a result, they will not invest in ICT systems adequately.

11-Lack of a national standard for ICT utilization in construction: Assigning a national standard of ICT for construction industry was mentioned as a vital need for this industry. This standard must force the construction companies to use a minimum level of ICT in their projects.

12-Low speed internet: Most of the interviewees were not satisfied with internet speed. The main problems associated to internet were low speed and frequent disconnection. Also no access to internet in undeveloped regions was a serious problem that construction companies have to solve it themselves.

13-Preference of in-person communication on electronic communication in construction projects: ICT provides electronic communication tools for construction projects. These tools reduce costs and time of in-person visits and meetings. However, sometimes construction practitioners, particularly managers, prefer in-person communication. That is due to a belief that better supervision can be done in physical meetings.

14-Complex and time-consuming process of getting permission for using ICT: being equipped with some electronic equipment like wireless communication or installing communication tools in place of projects, sometimes needs permission from government authorities. The process of getting permission from these authorities will be complex and time-consuming in many cases.

Quantitative data analysis

After the qualitative data analysis, the main problems of ICT utilization in the Iranian construction industry were ranked based on the severity. The result is presented in Table 1.

Table 1. Problems ranking of ICT adoption in the Iranian construction industry

Problem	N	Minimum score	Maximum score	Mean	Std. Devition
Weak ICT infrastructure	55	3	5	4.5636	0.56972
Low speed internet	54	3	5	4.4815	0.66562
Shortage of ICT training to construction practitioners	55	2	5	4.2727	0.78066
Possibility of data loss	54	1	5	3.9815	1.07266
Lack of a national standard for ICT utilization in construction	54	2	5	3.9815	0.81242
Poor support of ICT providers	54	2	5	3.9630	0.77613
Preference of in-person communication on electronic communication in construction projects	54	1	5	3.8704	0.91211
Low financial support of construction companies for investment in ICT	55	1	5	3.7455	1.04025
Lack of interest in using ICT tools among older construction practitioners	54	1	5	3.7407	0.91497
Information security and confidentiality	54	1	5	3.6852	1.06087
Complex and time-consuming process of getting permission for	52	1	5	3.5385	0.99925

using ICT					
Shortage of user friendly softwares	54	1	5	3.5	0.92655
Incompatible rules of construction industry with ICT	50	1	5	3.46	1.14660
Lack of trust in output of construction softwares	55	2	5	3.2909	0.95593

(N: number of responses)

CONCLUSIONS

This paper presents result of a quantitative analysis to rank the main problems and barriers of ICT utilization in the Iranian construction industry based on the severity of each problem. To reach this goal, after a set of interviews and identifying the main problems by qualitative analysis, a questionnaire is developed and distributed to highly experienced experts and managers of construction industry. The results of quantitative analysis reveal that the three main problems are weak ICT infrastructure, low speed internet and shortage of ICT training to construction practitioners. The future efforts to solve the major problems must be focused on improving ICT infrastructure. Internet speed and quality must be improved and internet access should be extended across the country. The construction personnel should be trained in companies based on the specific needs of that company. The security of information storages must be increased to avoid data loss and leakage. A national standard must be developed for using ICT in construction. ICT providers should support their products more and provide user-friendly programs with reliable outputs. Construction companies have to invest more in developing ICT in their organizations. The value of electronic communication should be explained to top managers and other personnel of construction firms. Particularly older people should be encouraged to use ICT. Authorities should adapt rules to modern world with new technologies and facilitate the permission of using communication equipment for civil activities.

THE 5D QS: TODAY'S METHODOLOGY IN COST CERTAINTY

David Mitchell[1] MRICS FAIQS

[1]*Partner, Mitchell Brandtman - 5D Quantity Surveyors & Construction Expert Opinion, 29 Woodstock Rd, Toowong, QLD, 4066, Australia. dmitchell@mitbrand.com*

ABSTRACT

This paper looks critically at where BIM implementation is on the pathway and sets out the opportunities that arise when 5D (the linking of cost information to a 3D model) is considered to be more than just a quantity take-off exercise. It proposes a methodology, from a practitioner's perspective, for applying 5D BIM to the design and construction of projects with the goal of delivering better buildings with cost certainty. A fundamental of the methodology is to use existing, proven technologies to overcome the problems that exist when the onus is on the BIM author to code model objects in a fashion that estimators can understand. The purpose and intention of this paper is simply to provide context and to start the discussion on what 5D BIM is with a view to developing a mainstream methodology that can be included within a BIM execution plan for a project.

Keywords: 5D BIM, Collaboration, Cost Strategy, Living Cost Planning, Transparency.

INTRODUCTION

To date, a lot of the focus on Building Information Modeling (BIM) implementation has simply been about design firms learning how parametric 3D modeling software works.

Design firms have been learning about the capabilities of their chosen BIM authoring tool, gauging the benefits to the firm, achieving a level of confidence in an isolated way and exploring collaborative work flows where information is exchanged in two directions.

Working against an even more collaborative approach is a belief that BIM can only add value to large projects and when Integrated Project Delivery (IPD) is the preferred delivery system. Whilst integration is the long term outcome, industry is currently grappling with the issues surrounding collaboration and is now starting to solve the stumbling blocks of liability, ownership and protection of data and intellectual property. The development of BIM guides and execution plans have made it possible to define expectations and clearly specify design deliverables at the various design stages.

[1] dmitchell@mitbrand.com

While these developments have been extremely encouraging in the area of 3D design very little development has happened in the fields of 4D - linking time and scheduling data; and 5D - linking cost data to the 3D model. For instance the Veteran's Affairs (VA) BIM guide simply refers to a "4D BIM - phasing plan" and the "discretionary additional use" of "5D - Material take-offs and cost estimating".

For BIM to be truly successful in providing better buildings then all of the D's need to be embraced. This paper will concentrate on 5D and what it can do, so that open discussion can occur and as an industry we can shift to practicing 5D and shaping it as a standard practice for the future.

Change and reform in the construction industry is long overdue, the catalysts for change are here and these will be the accelerators that drive the BIM process to become the industry norm rather than the exception.

CATALYST FOR CHANGE

The Global Financial Crisis and world events have made development and construction uncertain. World thinking has changed our behaviours. For the first time in decades people are saving, credit cards are being avoided and there is a growing sense of frugality.

When a consumer decides to spend, it seems that a "saved" dollar is more valuable than a "borrowed" dollar and that a "saved" dollar won't be wasted. Today's consumers are extremely well researched and won't be rushed because there is no compelling reason to buy. There is no fear that prices will rise because competition is rife, in fact delaying the purchase may mean that the product gets cheaper.

So it makes sense to take the time, to be certain that the product is reasonably priced, is of the highest quality and is supported with a strong level of service.

Previously this delay or slowness to purchase was seen as a lack of confidence in the future – something that will pass but now there is a growing realisation that structural change is occurring and that these conditions are here to stay. There is a new paradigm in play.

For the development and construction industry it is particularly difficult to meet this paradigm because past experience tells us that construction is expensive and it is uncertain. Often a customer does not really visualise what is being built until it is built and there is an expectation that there will be delays and cost increases.

Successful building is about creating certainty - in design, buildability and cost. Wisdom, intelligence and technology can create certainty by getting back to basics and making grounded decisions based on facts.

BIM PATHWAY

At present projects can confidently be managed using a staged and independent process of inputting data into independent models with the parties collaborating but not integrating to use the software in a beneficial way. For example, architects can set their design, engineers can create the structural framework and air-conditioning contractors can submit their components all independent of each other using different authoring tools. Software, like Navisworks and Solibri, are then used to bring each model together to deliver a coordinated design.

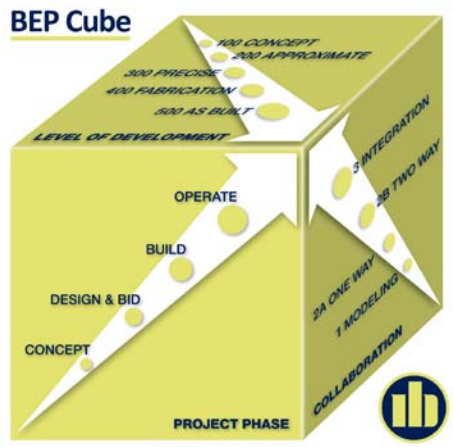
Andrew Gutteridge worked with the Australian Institute of Architects to champion the BIM pathway to provide a logical learning curve for the industry to move from

working in isolation to collaboration. The culmination of their work was production of a diagram "Towards Integration" which was later included within the CRC Construction Innovation publication - National Guidelines for Digital Modelling.

Using this diagram as a reference and applying it to the Australian industry, it was found that the mainstream uses 3D modeling in an isolated way (1B) and the cutting edge design teams are acting in a collaborative way (2A one-way and 2B two-way collaboration). Rather than spending time judging whether what is being done now is BIM or not BIM, it is far more important to acknowledge that industry is practicing and improving and that this is just part of the BIM pathway.

Industry design professionals are mostly engaged in the use of parametric modeling in one form or another but sceptics have a lack of trust in the software's intelligent design to fully integrate the model for each element.

Construction professionals also perceive a lack of protection of the input of information and data, if and when it is changed, by who and how it is tracked. What is important to remember is that even at 2A and B the duties and working practices for two dimensional work remain the same for three dimensional work.



At this point on the pathway it doesn't matter how you relate to parties throughout design, but rather that you do and that the obligations and design outcomes are clear.

Development of the BIM Execution Plan (BEP) has provided this clarity. The BEP defines the scope of design work, the Level of Development (LOD) and the two-way exchange of information for all parties to the project including the quantity surveyor (QS), cost engineer or estimator and can be clearly depicted on three scales – refer figure 1.

Figure 1. BIM Execution Plan Cube

CREATING COST CERTAINTY IN 5D

Developing certainty in cost, design and buildability reduces risk and creates better projects with sustainable profits. We know that 3D modeling and strong design coordination creates certainty in what is being built and that the 5th Dimension, or 5D, is all about cost. While there is considerable discussion and collaboration between different design partners often 5D is reduced to just the simple one liner of "Quantity Take Off" and attention is placed on coding by the designer with an expectation that later the costing process will be made easier.

This approach means that several opportunities are missed:

- The costs are not known until the model reaches LOD 300 or greater.
- The design itself is not tested at an early stage for functional efficiency or benchmarked against known elemental costs.
- There is no integrated cost plan and the design team is not provided with real-time cost feedback as the design progresses.
- The costing process is still a separate exercise which is not transparent.

An alternative and better approach is for the cost planner to push accurate cost codes into the model information and then to extract all of the information that is needed to complete a thorough cost estimate via a 5D BIM authoring tool. Part of this approach includes making allowances for work that has not yet or will not be modeled.

This approach means that all of the "missed opportunities" will be delivered and the result is a better building because the available money can be targeted at the most important features of the building design in a transparent way that builds trust amongst all project partners.

5D QS AND COST PLANNER

The modern QS is taking the traditional QS role to the next level, utilising models to provide detailed and accurate 5D estimates and living cost plans. This assistance is provided to projects at any phase from concept design through to construction and completion.

The ability to complete a series of estimates for various designs at the early phase of a project is paramount because this is when the dye is set, planning evolves and cost overruns are avoided. If the scope of a project matches the budget at the outset then constant redesign is avoided and the priority features of the project are included.

It is well established that early decisions have the highest level of influence on project outcomes at the least cost. This is because redesign, construction delay and disruption, change order and rework costs are avoided.

The technique is simple, basically an estimate is done, then its elemental costs are benchmarked and the functional performance of the design is analysed and tested against competing projects. The QS then provides feedback to the concept designers, a new scheme is produced and the process is completed again.

Once the project design passes this budget test and proving up phase then the Cost Plan is established for the project and this recipe becomes the basis for managing and monitoring the fluctuating construction costs during design.

A 5D QS can do this extremely quickly, an endless number of times and in a complexity of combinations. For a 2D QS this is not possible because project schedules do not allow enough time for endless manual take-offs and even if there was, then the re-measurement process is too labour intensive to be viable, the combinations that need to be considered are too complex and there are too many variables for a QS to complete the required "what if" style calculations manually.

The traditional process is to complete the design to a particular stage i.e. schematic design, developed design, etc.; then freeze further design until an estimate is completed and permission is granted to proceed to the next design stage.

Today there are modern techniques for the 5D QS to use within the traditional frameworks to set cost strategies and a 5D Cost Plan (or Living Cost Plan). These techniques can be blended within the traditional design and construction phases as follows:

CONCEPT DESIGN

At the feasibility and concept design phase, a cost strategy is set that considers all aspects of the project, the client's brief, the designer's vision and the site constraints. The strategy is developed after first completing a concept estimate and then testing its

 ISBN: 978-1-84219-840-7 .

elemental costs by benchmarking and the design efficiency by analysing its functional performance.

Initial Concept Estimate – LOD 100

The initial concept estimate is a fast and effective way to determine the cost of a project and allow decisions to be made quickly and with certainty.

Working with the overall massing model (AIA LOD 100) in Sketchup, Revit or an IFC format, the 5D QS prepares a concept estimate that is presented in an elemental format and sets out each elemental unit rate and quantity. It is understood that not everything is modeled and the 5D QS uses experience to ensure that the total project is included within the estimate. This is done by supplementing the model information with 2D on screen measurement where necessary.

This concept estimate becomes the basis for recompiling the estimate to consider alternative designs during the proving phase of the concept design.

Elemental Cost Benchmarking

The 5D QS uses cost intelligence from past experience and actual project cost data to critique, review and compare the elemental costs contained in the initial concept estimate to other similar or competing projects. This exercise identifies inefficiencies and highlights opportunities that will benefit the project bottom line. Cost benchmarking is done on an elemental basis because this provides the most consistent results; examples of building elements include substructure, columns, upper floors, staircases, roof, external walls, etc and are fairly consistent around the globe. Some of the different elemental formats include UniFormat II (USA), UniClass (UK) or ACMM (AUS).

By way of example a concept estimate containing a rate of $354.90 per m2 for columns and upper floors would exceed the actual average costs of $279.09 per m2. If the design is made more efficient a cost saving of 3.6% against the estimated total building rate of $2,078.57 per m2 is achieved.

Analysis of Functional Performance

In a similar fashion the functional performance and efficiency of a building is analysed against actual project performance data to further identify inefficiencies and highlight opportunities to create further savings.

	Planned Project Concept Design	**Actual Completed Projects (Average)**
Residential Area / Unit	98.5m^2	65.3m^2
Common Area / Unit	30.9m^2	11.6m^2
Carpark Area / Unit	39.5m^2	25.0m^2
Building Area / Unit	**168.9m^2**	**101.9m^2**
Residential Area / Unit	98.5m^2	65.3m^2
Balcony Area / Unit	33.5m^2	12.9m^2
Saleable Area / Unit	**132.0m^2**	**78.2m^2**

Table 1: Functional Performance Analysis

 ISBN: 978-1-84219-840-7 .

In Table 1, the example concept design for a planned apartment building contains 36 apartments with an average area of 168.9 m2. This exceeds the completed project average of 101.9 m2. It is also apparent that much of the inefficiency is occurring within the common spaces and car park areas which are not income producing. Correction of these inefficiencies would improve the building cost performance by 20% without effecting the saleable area and income.

DETAILED DESIGN

At detailed design, the goal of the 5D QS is to produce a schematic design estimate with dynamic links to the model information that will form the foundation for the living cost plan that is used for developed design and bidding. The living cost plan becomes the basis for providing updated estimates every time the model information is changed that can be used for forecast final cost, budget variances, value management, finance, funding and final investment decisions or in negotiations with a contractor.

Schematic Design – LOD 200

Working with the schematic design model (AIA LOD 200) in Revit or IFC format, the 5D QS prepares a sketch design cost plan that is presented in an elemental format stating the generic construction materials, finishes and services specifications.

The 5D QS maps the model and adds an elemental pricing code to the model information. It is helpful if the author has included UniFormat II (USA), UniClass (UK) or ACMM (AUS) codes in the model information but often it is much quicker and more accurate if the 5D QS adds the preferred codes for the task.

Dynamic links are then created between the generic architectural and structural model elements, the 5D QS elemental rate library and the selected project template that is contained within the 5D BIM authoring tool such as CostX.

It is understood that not everything is modeled and the 5D QS ensures that all of the work is estimated by supplementing with 2D on screen measurement where necessary. Trust and transparency is supported by providing a fully functioning and executable CostX reader version of the sketch design cost plan that is easily interrogated because of the dynamic links between the models, elemental areas and rate library. This executable file becomes the basis for the living cost plan which can be recompiled to consider alternative designs, different construction methods, materials and generic engineering systems during development of the schematic design and any time the model information is revised.

Developed Design – LOD 300

Working with the developed design model (AIA LOD 300) in Revit or IFC format, the 5D QS prepares developed design cost plans that are presented on a sub-elemental and trade basis, stating the specific construction materials, finishes and services specifications. The final estimate states each sub-elemental unit rate and quantity.

At this stage an extra level of costing detail is added to the model information. This can be done via key notes and then the model is re-mapped where necessary to create further dynamic links between the specific model assemblies (including architectural, structural, civil and MEP), the detailed rate library and the selected project template that is contained within the 5D BIM authoring tool. Again the model information is supplemented with 2D on screen measurement and the executable file continues to be the living cost plan This detailed information can factor into the different stages of the

design and construction process and helps to consider in detail the labour, materials, equipment, and subcontractor costs for each building element.

Coding
In circulation today there are a number of different coding systems but there is not a published industry code that is suitable for becoming a price code which will automatically link a rate to a specific system or assembly. UniFormat II is one example and while it is close to achieving this goal it has insufficient levels to specifically identify the material and fixing condition. For these reasons the 5D QS uses its own specific code for the material and fixing conditions which is pushed into a model as a key note.

QUANTITY TAKE-OFF AND BIDDING

For design, bid, build procurement the rate library is removed from the executable file so that what remains is a bill of quantities that is easily interrogated by contractors and subcontractors because the dynamic links allow each quantity to be viewed in the model. The file is also recompiled in a trade format so that the quantities reflect the scope for each subcontract. Often the building information comprises individual models and the 5D QS uses tools like Navisworks and Solibri to coordinate visually. MEP forms approximately 30% of the total project cost so special care is needed during this phase to ensure that quantities for mechanical, electrical, hydraulic, fire and transportation services are actively coordinated with the building trades.

CONSTRUCTION

Contractors Priced Bill of Quantities – LOD 300
Working with the construction model (AIA LOD 300) in Revit or IFC format, at the commencement of construction, the 5D QS attaches the contractor's offered rates and prices to the executable file. The contractors priced bill of quantities is presented on a trade and zone basis and states the description for each item (including the specific construction materials, finishes and services specifications), the quantity and the offered rate. In some instances re-mapping of the model is necessary to create further dynamic links between the model zones and specific assemblies.

Change Orders, Variations and Payments
The dynamic links mean that variations and change orders can be calculated reliably, easily and quickly every time a change occurs in the model information. Progress payments are also calculated from the executable file by isolating the completed zones by trade and recompiling the quantities to produce a progress payment calculation that is transparent and easily interrogated.During construction the model will evolve from LOD 300 to LOD 400 as changes occur on site and shop drawings are developed. The 5D QS continually coordinates the construction model with the contractors priced bill of quantities and provides cost updates, budget performance and variances through each stage of construction.

Cost Integrated Construction Model – LOD 400
As construction progresses the model information is changed to produce the revised documents that are necessary for the construction process – this information is stored in the Model software. The 5D QS also changes the cost information to reflect the actual contract sum and any cost adjustments and payments that occur during construction – this information is stored in the 5D BIM authoring tool.

As-Built Cost Data & Facilities Management – LOD 500

Once validation and synchronization is completed between the as-built (AIA LOD 400 or 500) Model and the FM system, The 5D QS pushes the project as-built cost data into the Model key notes. The as-built cost data packet usually comprises several different pieces of information including the replacement cost at the base date, manufacturers expected life for replacement, effective life for depreciation and estimated running cost for operating budgets. Care is taken to omit construction costs that will not be incurred again such as demolition of pre-existing buildings.

This as-built cost information is then ready to be integrated into the Facility Maintenance System and FM database for use throughout the life cycle of the project.

CONCLUSION

The 5D QS has developed specialist technology skills which compliment traditional cost planning techniques that set strategies from preliminary designs when plans evolve and cost overruns are prevented. 5D BIM provides the ability generate savings and efficiencies and to drive costs for buildings, infrastructure, heavy engineering or land development in the direction that is wanted. When negotiating with contractors and subcontractors the ability to visualise quantities creates trust and is relied upon.

5D BIM is here and finally there is traction to make 5D an integral part of the QS tool kit and every project to create cost certainty. It is one thing to use the technology but on its own it will not generate the certainty that customer's desire.

This requires the wisdom and intelligence of a 5D QS and cost planner. So while it's the way of the future and a must for all projects going forward, it is critical to work with people who know what they are doing and know how to leverage it to get the best results for the building from initial concept through to procurement and on-going management of post construction.

UK GOVERNMENT BUILDING INFORMATION MODELLING (BIM) STRATEGY

Joe Martin[1]

[1]*Executive Director, Building Cost Information Service (BCIS), RICS, Parliament Square, London, SW1P 3AD, UK*

ABSTRACT

The UK Government's construction strategy is committed to deliver a structured Government/Industry capability to increase BIM take-up over a five year horizon as part of a joined up plan to improve the performance of the government estate in terms of its cost, value and carbon performance. The strategy was announced in June 2011. The strategy requires the Government to clearly define the data that it requires from the BIM while leaving the industry to take responsibility for the BIM infrastructure. The Government has started to run pilot projects and gain some first hand experience of the benefits while fleshing out the detail of its requirements. The industry is keen to respond particularly those firms that work for Government departments. The use of BIM tools has been patchy and have tended to be 'lonely BIM' used by individual consultants and contractors to improve their performance rather than 'project BIM' that will improve performance of the team through collaborative working.

Key words: Building Information Modelling (BIM), Procurement, Information management, Collaborative working.

INTRODUCTION

An industry working group was invited by The Department of Business Innovation and Skills (BIS) and the Efficiency Reform Group from the Cabinet Office (ERG) to look at the construction and post-occupancy benefits of BIM (Building (asset) Information Modelling and Management) for use in the UK building and infrastructure markets.

THE PAPER DESCRIBES THE WORKING GROUP'S RECOMMENDED STRATEGY, WHICH HAS BEEN ADOPTED BY THE GOVERNMENT. THE OBJECTIVE IS TO DELIVER A STRUCTURED GOVERNMENT/SECTOR CAPABILITY TO INCREASE BIM TAKE-UP OVER A FIVE YEAR HORIZON AS PART OF A JOINED UP PLAN TO IMPROVE THE PERFORMANCE OF THE GOVERNMENT ESTATE IN TERMS OF ITS COST, VALUE AND CARBON PERFORMANCE.

[1] jmartin@bcis.co.uk

 ISBN: 978-1-84219-840-7 .

THE REPORT

Issues, Barriers and Solutions

The Working Group set up nine sub-groups to look at individual issues whose reports make up the Appendices to the strategy report.

- Digital capabilities
- Legal, contractual and insurance
- Delivery standards and processes
- Education, training and support
- Improved information handover
- Information use and benefits
- Communications and Institutional support
- Investment
- Programme

There is a target for all suppliers of construction services to Her Majesty's Government (HMG) to have reached the ability to deliver information and services of at least that of Level 2 in the maturity model (see below).

Next Steps

The strategy calls for the setting up of:

- cross-government 'implementation and mobilisation' Task Group to include local and regional government to
  - Identify current capabilities
  - Consider information needs to ensure consistency and clarity to supply chain
  - Find demonstration projects
- a client/industry group to develop a funded mobilisation plan to include:
  - Creation with British Standards Institute of a deliverables framework
  - Tailor COBie methodology
  - Create metrics to monitor outcomes
  - Consider contractual requirement

The Hypothesis

Rather than define BIM it sets out a hypothesis and a number of tests to guide and validate the proposed strategy focussed on the outputs of BIM. The hypothesis is:

> 'Government as a client can derive significant improvements in cost value and carbon performance through the use of open shareable asset information.'

The tests are that the BIM implementation should be:

- Valuable
- Understandable
- General
- Non-Proprietary
- Competitive
- Open
- Verifiable
- Compliant

BIM Maturity Model

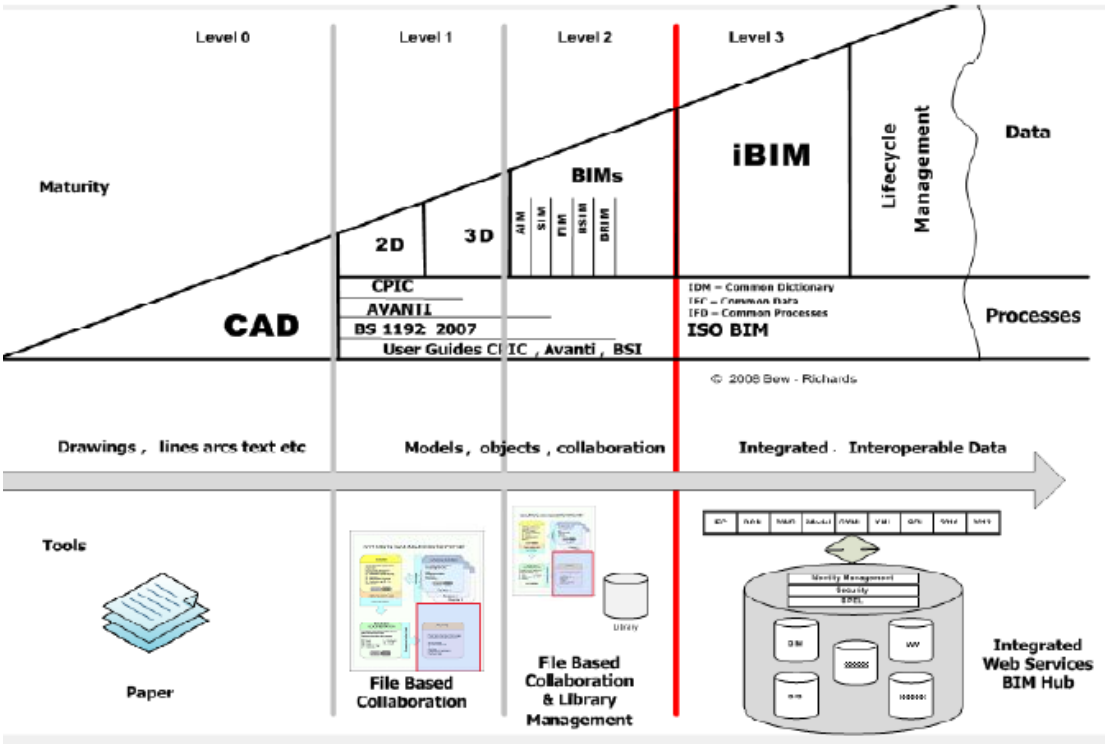
Defines the competence and delivery from a BIM. It illustrates it with the 'Wedge' diagram that has become the industry standard. See Figure 1.

The levels are defined as:

0. Unmanaged Computer Aided Design (CAD) probably 2D with paper (or electronic paper) as the most likely data exchange mechanism
1. Managed CAD in 2 or 3D format using BS1192: 2007 with collaboration tool providing a common data environment, possibly some standard data structures and formats. Commercial data management by stand alone finance and cost management packages with no integration.
2. **Managed 3D environment held in separate discipline 'BIM' tools with attached data. Commercial data managed by an ERP. (Note: 'Enterprise Resource Planning' software) Integration on the basis of proprietary interfaces or bespoke middleware could be regarded as 'pBIM' (proprietary). The approach may utilise 4D programme data and 5D cost elements as well as feed operational systems.**
3. Fully open process and data integration enabled by 'web services' compliant with the emerging Industry Foundation Class/International Framework for Dictionaries (IFC/IFD) standards, managed by a collaborative model server. Could be regarded as iBIM or integrated BIM potentially employing concurrent engineering processes.

To get the industry to Level two in five years is the Government's target.

Figure 1 – BIM Maturity Model



Source: Strategy Paper for the Government Construction Client Group From the BIM Industry Working Group –BIS, March 2011

 ISBN: 978-1-84219-840-7 .

International Alliances
The working group established relationships with established BIM experience elsewhere particularly within the American Government - US Federal Facilities Council, the US National Institute of Building Science (NIBS) and the General Services Administration (GSA).

Legal, Contracts and Insurance
The working group addressed the following issues covering:

- Copyright and Intellectual Property (IP)
- Ownership and sharing of data
- Insurance and liability
- Integration with existing contracts
- Commercial issues- procurement practice, approval and payment
- Maturity model – prioritisation for developments.

The conclusions include:

- That IP will not be a barrier to BIM adoption.
- That BIM competence should be a pre-qualification issue and not part of the selection and appointment process..
- Simple standard contracts amended should be produced requiring BIM compliance.
- Establish standard protocol setting out consistent requirements for project delivery and outputs.
- Define duties for consultants and contractors working in a BIM environment.
- Define duties for the new role of 'model manager' and relationship to others.
- Clients should expect ***'Quantity Surveyors (QS) and Project Managers to be familiar with BIM and actively develop ways in which processes can be made more cost effective and value adding'***.

There is a section on integration of cost management and programme outputs into a BIM model, which states:

'Much BIM software is capable of producing "schedules of quantities" and enabling the Construction sequence to be simulated prior to construction. This capability would suggest that Cost Management and Programming activities can be readily brought into the BIM environment – particularly at earlier stages of design development. However, the effective adoption of BIM technologies by cost consultants and planners has been slow to date, and should this situation remain, then cost and programme services will not benefit from the productivity and speed of response that a settled BIM process can offer. This is not to say that the adoption of BIM will not be without its challenges, but that the ***professions cannot afford to be outside of the BIM loop.'***

It also states that ***'methods of measurement and duties may need to be reviewed to ensure that the appropriate information is produced so that measurement can be automated to a greater degree…Measurement will be accelerated but discretionary skills will still be necessary.'***

 ISBN: 978-1-84219-840-7 .

Process and Documentation
The report sets out the standards and guidance required to deliver the strategy. British Standards Institute (BSi) B/555 is identified as the key producer of guidance, with a third party, potentially the Construction Project Information Committee (CPIC), producing the guidance required to deliver level 2 documentation. It details the BSi, International Organisation for Standardization (ISO) and other standards available and under development.

Education and Training
The report identifies the requirement for training graduates and current industry practitioners and the role that universities and Institutions will have in raising awareness and delivering training. Including the requirement for Institutions to encourage BIM capabilities to their membership

Identifies the need for training and education to support:

- Awareness
- Provide guidance and toolkits
- Technical skills
- Non-technical, ancillary skills
- Accreditation
- Review and benchmarking
- Post project evaluation

BIM Deliverables
The information required on a capital project is identified at each stage of the Office of Government Commerce (OGC) project gateway.

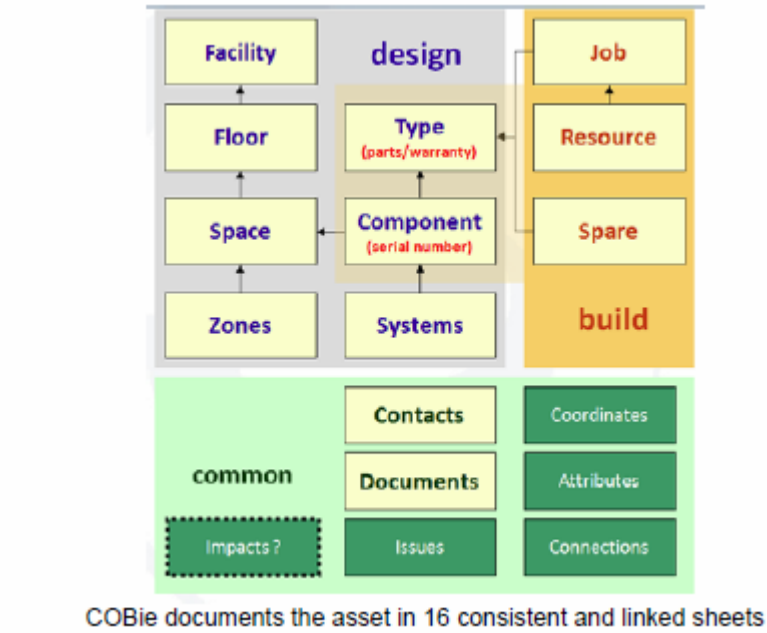
It identifies when costs are required and what information will be available at these stages. It alludes to Life Cycle Cost and carbon data but does not cover output to Facilities Management. The data requirement needs to be mapped to the 'COBie data definitions'.

COBie stands for 'Construction Operations Building information exchange'. It is a means of sharing, predominantly non-graphical, data about a facility. It was developed in America and will need to be adapted for use in the UK and in Infrastructure. It is a non-proprietary format based on a spreadsheet so it can be managed by organisations of any size at any level of IT capability but can be linked to other systems and software. See Figure 2.

COBie transfers information to owner/occupier to manage their assets efficiently. It documents the asset in 16 linked spreadsheets.

COBie will be adopted as the standard means of reporting data from a BIM. Reporting at specific stages is referred to as a 'COBie data drop'.

Figure 2 – COBie format



Source: Strategy Paper for the Government Construction Client Group From the BIM Industry Working Group –BIS, March 2011

Handover Information

The report details how handover can be improved by delivery of consistent data through COBie, but that it requires localisation for UK to support carbon related decision-making and extended to accommodate infrastructure owners.

Implementation relies on three primary functions:

- **Gathering** asset information
- **Maintaining** the information
- **Using** the information

The data to be provided (data drops) are identified at four key stages of a capital project mapped to various process maps used in the UK, e.g. Royal Institute of British Architects (RIBA) plan of work, Office of Government Commerce (OGC) Gateways, Network Rail's Governance for Railway Investment Projects (GRIP) stages, etc. The Key stages are identified as:

1) To check design brief against clients brief and provide cost plan and risk management
2) To check tender design against project brief, cost plan, environmental requirements and provide tender transparency
3) To check detailed design and contract packaging for scope, cost and carbon
4) To provide and check handover data, actual cost, actual programme, actual carbon performance.

Caveat

'The key principle of the strategy is that the Construction Industry will respond to the opportunity created by government with innovation and solutions, the Government Construction Client should anticipate some inertia, should aim to encourage a single voice in the industry and be prepared to manage the outcomes of the initial development work streams.'

EVIDENCE OF IMPROVEMENTS RELATING TO BIM

The first UK Government pilot projects procured with a project BIM in accordance with the strategy are yet to report costs and savings, but what evidence there is to savings resulting from the use of BIM tend to relate to the use of BIM by individual participants in the process; consultants or contractors, 'lonely BIM' as distinct from a 'Project BIM' used by all participants.

For example:
A Stanford University report (Gao and Fischer, 2008) based on 32 projects showed:

- Up to 40% elimination of unbudgeted change.
- A savings of up to 10% of the contract value through clash detections
- Up to 7% reduction in project time.

And a report by Holder Construction (Himes and Steed, 2008) on an individual project showed:

- $90k cost of BIM
- Identification of 590 M+E clashes
- Savings of $800k

CONSTRUCTION COST MANAGEMENT AND BIM

There is an on going dialog between BCIS and the BIS implementation team about classification of costs and measurement rules to be adopted in the data drops.

In many cases a budget expressed as an elemental cost model will be prepared as part of a business cases, before the BIM is set up. Therefore as the model is developed it needs to support the measurement required to report costs against the budget in an elemental form.

For the QS to reap the efficiency benefits from the BIM process measurement rules and cost reporting requirements need to form part of the client's 'Employers Information Requirement' for BIM.

CONCLUSIONS

The strategy is described as 'Push-Pull'. 'Push' being things that the supply side of the industry should do to facilitate the use of BIM and 'Pull' being the requirements that the client side needs to demand to specify, collect and derive information to add value.

The time scale for the strategy is five years.

There are six key recommendations summaries as follows:

- Make the supply side responsible for the BIM infrastructure.
- Client contract requirements for deliverables and responsibilities must be clear and specific.
- Client must use the required information and be transparent as to how it influences key decisions in both delivery and operational phases of a project.

- A level of investment will be required to provide the infrastructure but the technology need be no more complex than systems already in use by the industry.
- Changes in requirements should be made in small but significant steps.
- The Governments target is for all projects to deliver information at the 'level 2 of the maturity model' (i.e. from 3D models for separate disciplines (architecture, structural, services, FM etc) together with programme data an costs) within the five-year horizon. - ***But never underestimate the power of inertia!***

The clients 'Employer's Information Requirements' need to include requirements measurement and cost reporting.

STAKEHOLDER MANAGEMENT AND CORPORATE CULTURE IN THE UK CONSTRUCTION INDUSTRY

Jason von Meding[1], Kevin Kelly, Lukumon Oyedele and John Spillane

[1]*Queen's University of Belfast, School of Planning, Architecture & Civil Engineering, David Keir Building, Stranmillis Road, Belfast, BT9 5AG, Northern Ireland.*

ABSTRACT

Traditionally stakeholder management and corporate culture have been seen as two very different knowledge areas. It is important for this study to investigate the two within the context of the UK construction industry and attempt to generate a framework that demonstrates the dependency of each on the other. The wider research project employed both qualitative and quantitative research methods, including semi-structured interviews, cognitive mapping and questionnaire survey. This paper will specifically present some of the quantitative results as well as theory generated by the study. The data suggests that stakeholder management and corporate culture are key areas of an organisation's success, and that this importance will only grow in future. In addition, it was discovered the UK Construction Industry has not yet fully accepted stakeholder theory. Evidence of a relationship was established between the two theoretical areas and a framework developed and quantified. It is evident that change is needed within the UK construction industry. Companies must employ ethical and social stakeholder management and manage their corporate culture like any other aspect of their business. Successfully doing this will lead to more successful projects, better reputation and survival. The findings of this project begin to show how change may occur.

Keywords: corporate culture, framework, stakeholder management, theory, UK construction.

INTRODUCTION

According to Jongbloed et al. (2008) the current application of stakeholder management in theory comes from the Stanford Research Institute which in 1963 used the term to expand the belief that shareholders were the only group management needed to be concerned with (Mainardes et al. 2011). The term stakeholder first came to light in the business world with *Strategic Management: A Stakeholder Approach* written by Freeman in 1984. The concept took even greater importance given public interest, media influence and ethical concerns about the conduct of businesses (Mainardes et al. 2011).

[1] j.vonmeding@qub.ac.uk

 ISBN: 978-1-84219-840-7 .

In recent years construction companies have realised that it is important to fully embrace 'stakeholder theory' due to the increasing diversity, power and influence of stakeholders. Within the UK construction industry project success has become measureable by more than profit and client satisfaction. Companies are now expected to deliver projects with social value, sustainability and consideration of all stakeholder needs.

Corporate culture, meanwhile, is 'a set of morals, values, attitudes, beliefs and meanings that are shared by the members of an organisation (Williams, et al. 1993.) As such, it influences the way in which a business conducts itself. Culture allows business to differentiate itself from others, but still remains one of the most difficult aspects of business to understand. According to Schein (1985), if the construction industry is to become more efficient and effective it must understand the role culture plays. Ankrah and Proverbs (2004) suggest that culture has been used as the 'black box' for many of the construction industry ills. They argue that this is unfair given the lack of research into the area.

This particular study aims to investigate current stakeholder management practices and corporate culture norms within the UK construction industry and to generate new theory that links the two, with qualitative and quantitative data to support the proposed framework. We will be able to determine whether the UK construction industry has embraced stakeholder theory and whether a relationship exists to corporate culture.

Stakeholders

Freeman (1984) defined stakeholders as 'groups or individuals who can have effects on, or are affected by, the objectives of an organisation.' Starik (1994) refined this saying that stakeholders could also be those who are, or could be, influenced by or could themselves influence an organisation (Kolk and Pinkse 2006). It is widely accepted that stakeholders have a claim or interest in a project and its activities (Nguyen et al. 2009; Mitchell et al. 1997; McElroy and Mills 2007).

Many parties have been identified as stakeholders, from both within and outside of a firm's direct operations. Project managers, site personnel, contractors, sub-contractors, local government, communities, media and professional bodies have all been cited as possible stakeholders (Newcombe 2003; Ward and Chapman 2008; Chinyio and Akintoye 2008).

Stakeholder Management

According to Jones and Wicks (1999) and Savage et al. (2004) there are numerous basic principles of stakeholder theory. Firstly, the organisation enters into relationships with many groups that are impacted on or have the ability to impact on an organisation (Mainardes, et al. 2011). Stakeholder management is about understanding the nature of these relationships.

Modern procurement methods have led to a higher number of stakeholders for construction projects to contend with. The very existence of relationships means stakeholders need to be managed. Chinyio and Akintoye (2006) suggest that a number of stakeholders mean that participants are not always going to be in agreement. The

different interests represented can influence and at times threaten projects (Freeman 1984; Cleland 1999).

Likewise, Cleland (1999) suggests that success in construction projects is significantly dependent on meeting the needs of stakeholders. Bourne and Walker (2005) attribute many project failures to poor consideration of stakeholder needs. In their study of public-private infrastructure projects, El-Gohary, et al. (2006) claim that stakeholder input is crucial. Waddock et al. (2002) suggest that stakeholders need to be managed due to pressures not only from stakeholders themselves but because of social trends and institutional expectations, as well as serious ethical and legal obligations.

Stakeholder management approaches

Smyth (2008) suggests that the most common form of stakeholder management used in construction is utilitarianism. This approach is largely concerned with maximising the utility of a firm in terms of profit and growth. Newcombe (2003) agrees with this, suggesting that there is a 'Machiavellian approach' to stakeholder management that is more pragmatic than ethical. He suggests that a more 'Kantian approach' will become the norm where the project will be managed to the benefit of all stakeholders and trusting relationships will be formed.

By the same token, Bourne and Walker (2005) believe stakeholder management should be approached in a corporately responsible way. Part of this, they state, is to adapt a sustainable approach to projects while simultaneously learning and innovating. On the other hand, Kolk and Pinkse (2006) describe 'stakeholder mismanagement,' characterised by a lack of moral responsibility.

Corporate Culture

The mostly widely accepted definition of corporate (organizational) culture is given by Schein (1985). He describes it as a pattern of shared assumptions that a group learns from the successful confronting of problems. He indicates that this can then be taught to new members of a group as the correct way to feel and face problems.

The meaning of culture will differ depending on a number of factors such as industry, business or leadership. Zabid and Rashid (2003) suggest that while numerous definitions of culture exist, it is seen as holistic, historically determined and socially constructed by all. Despite the clear importance of culture, Williams et al. (1993) say that little attention is given to the practical procedures of managing culture.

Zabid and Rashid (2003) suggest that management and leadership style are important aspects of any company. This view argues that leadership and not simply management is important to establish a strong and positive culture. Many academics suggest that another internal stakeholder, the employee, is an important driver of culture within an organisation. Zabid and Rashid (2003) concur, citing in particular that employees' attitude and behaviour as vital factors.

The Importance of Corporate Culture

Schein (1985) indicates that culture is important because it is a powerful, latent and mostly unconscious force that impacts on the behaviour of those within a company. Assessing it allows managers to better understand their company and how to improve,

 ISBN: 978-1-84219-840-7 .

responding to the business environment. Schein (1985) further suggests that culture is one of the last mechanisms that the companies within the construction industry have available to improve their competitiveness.

Cameron and Quinn (1998) developed the Competing Values Framework in an attempt to classify culture types. Within this model four culture types were identified; hierarchy, market, clan and adhocracy. Each of these cultures displays their own characteristics. In order to assess the dominant orientation of an organisation the Organisational Culture Assessment Instrument (OCAI) was developed (Oney-Yazici 2006). Based on these studies, Fig. 1 represents the culture types considered further in this research.

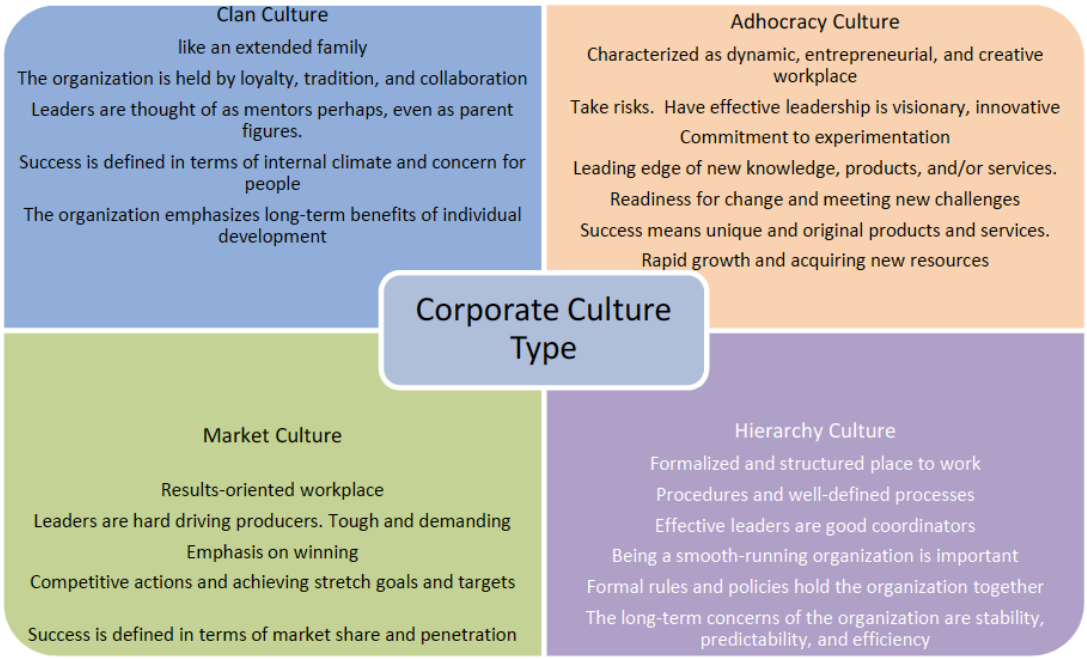

Figure 1. Culture types. Source: authors from Cameron and Quinn, 1998 and Oney-Yazici 2006

The primary reason that culture influences and impacts on stakeholder management is that culture guides the behaviour of those in the company (Galbreath, 2010). As Schein (1985) found, culture is one of the main ways that social organisations are connected to their environment.

METHODOLOGY

This paper examines some of the quantitative findings and theory development to emerge from a mixed-methods study conducted in 2011. 5 exploratory interviews were conducted with internationally experienced construction professionals and the information resulting was combined with existing knowledge based on previous literature to produce a questionnaire survey.

The questionnaire investigated both culture types within UK construction firms and prevalent stakeholder management approaches. 300 requests were made for participation via email and 45 responses were received for a 15% response rate.

FINDINGS

Fig. 2 shows in the second column the distribution of culture types within the UK. According to this research the construction industry is made up of three main culture types (90%). Type A, the clan culture; type C, the market culture and type D, the hierarchy culture. Type B, the adhocracy culture was less present within the industry, according for only 10% of the sample. This would suggest that the UK Construction industry culture quite possibly lacks entrepreneurial, creative and innovative characteristics.

The fourth column shows how the four stakeholder management extremes are represented within the UK construction industry. Sixty-six per cent of companies claim that their stakeholder approach is dominated by stakeholder management extreme 1, the Ethical and Social approach. It is interesting to note that all professionals surveyed confirmed that they practiced some form of stakeholder management.

However, these results also show that 34% of the industry falls into stakeholder extreme groups 2 and 3; the utilitarian positive and negative approaches respectively. This implicates that just over one third of UK construction companies put self-interests and economics ahead of stakeholder interests.

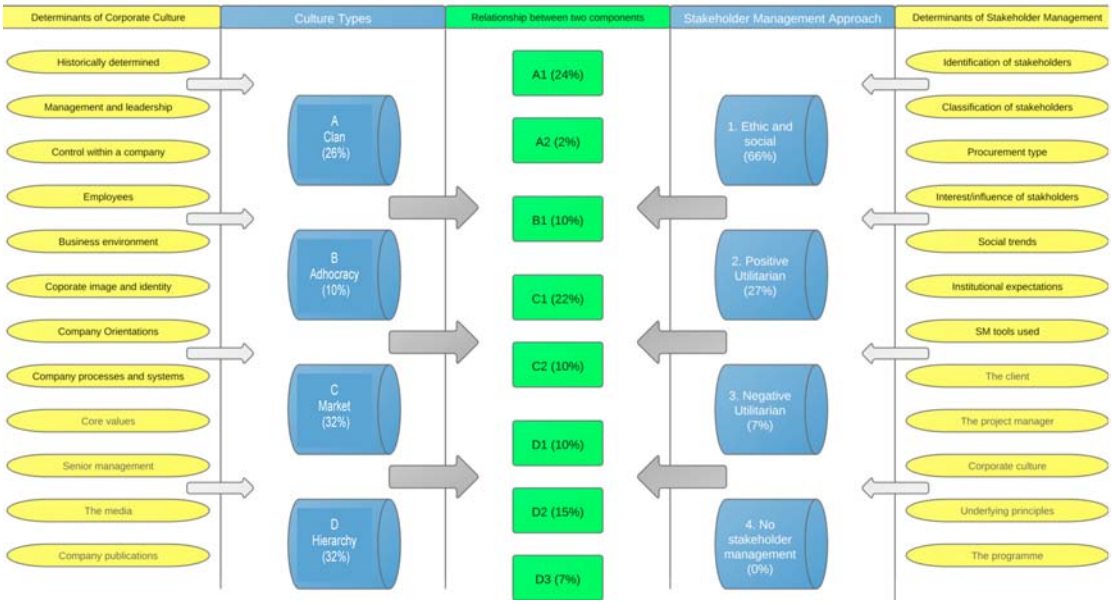

Figure 2. Stakeholder Management/ Corporate Culture Framework in UK. Source: authors

It can be seen from the framework that the UK construction industry is dominated by organisations of clan (A) and market (C) culture types, approaching stakeholders in an ethical and social way (approach 1). Interestingly it can be that the seven per cent that fell into stakeholder approach 3 (negative utilitarian) also fall into culture type D, the hierarchy culture. Perhaps it is their formalised and well-defined processes that contribute to this. Such companies often show resistance to change and perhaps this is why stakeholders are approached negatively.

DISCUSSION

This research found that the UK construction industry believes that stakeholder management that helps deliver profit and growth is the most successful, and this carries certain dangers. Many companies put self-interest above all else and this can seriously impact stakeholder management, hindering optimum results. There are many benefits to a more inclusive stakeholder approach, including long-term relationships and improved corporate image and reputation.

For the UK construction industry corporate culture is the ethos, beliefs and behaviours of an organisation. Furthermore it describes the systems and processes used to conduct business. Most employees that discussed this research described their organisational culture as good and this suggests that organisations within the UK industry appoint individuals that match their culture type. Alternatively, perhaps employees are drawn to companies that have a similar belief system to themselves.

As discussed earlier within this research corporate culture within the construction industry was determined based on a set of four typologies; clan, adhocracy, market and hierarchy culture. The research suggests that there is a healthy mix of these culture types within the UK construction industry. The market and hierarchy types were most prevalent. This indicates that the UK construction industry is mostly made up of companies that are results orientated, that aim to be the market leader and outpace their competition; and on the other hand organisations who are very formalised and structures and are driven by well-defined procedures and processes.

As Galbreath (2010) suggested, the primary reason that culture influences and impacts on stakeholder management is that culture guides the behaviour of those in the company. The questionnaire allowed for the idea of a relationship to be tested within the UK construction industry based on the stakeholder approaches and corporate culture types that were determined. Evidence was found of a relationship between the two theories. For example, clan culture almost entirely corresponded with ethical and social stakeholder management. Given this culture is described as being family-like and that success is defined in terms of people perhaps this is unsurprising. Likewise, adhocracy culture recorded entirely ethical and social stakeholder management scores. However, unlike clan culture, this culture is typified by innovation and risk taking. Perhaps, this willingness to engage new ideas and readiness for change explains why these firms approach stakeholders in an optimal way. This research has highlighted the growing importance of stakeholders within the construction industry; it appears that given the dynamic attributes of adhocracy culture they have been able to clasp this significance and stakeholder management effectively.

Market culture also correlated largely with ethical and social stakeholder management; however some positive utilitarian approach was also present in the findings. Market culture's strong stakeholder performance may be attributed to a competitive nature and emphasis on winning. Notably these characteristics can on occasion lead to a utilitarian approach. Being very results orientated may suggest that companies would act in self-interest, yet it was found that an ethical and social approach was common. This seems to suggest that ethical and social stakeholder management is also best for a company's interest and will deliver better results for the company. Unlike the other stakeholder typologies hierarchy culture does not approach stakeholders in an ethical and social manner. Hierarchy culture is dominated by

positive utilitarian stakeholder management; this is to say that their interests are put first.

Given the prominent features often associated with this culture type it is conceivable that this is an unintentional outcome. Due to the structured and process driven approach of hierarchy culture, maybe this approach is due to habit more than anything else. There are no obvious reasons apart from this why hierarchy culture would approach stakeholders in this way. Possibly it is their reluctance to embrace change and unwillingness to take risks that lead to this stakeholder approach.

It is evident from the findings that many companies within the UK construction industry must address issues within their stakeholder management approach. Given the relationship demonstrated between stakeholder management and corporate culture this may implicate that these companies must also change their corporate culture. On an individual organisational level, a better understanding and management of business processes and behaviours is essential.

CONCLUSIONS

It is obvious from this research that stakeholder management and corporate culture are important considerations for the UK construction industry and will increase in stature with time. However, the problem remains that the construction industry has not yet fully integrated a stakeholder agenda that takes this into consideration. This needs to change if the industry is to improve its performance and reputation.

In addition, as Williams et al. (1993) found there is too little consideration given to the day-to-day management of culture. It has been described by many as the primary way an organisation can distinguish itself from another and also represents one of the last sources of competitive advantage (Schein 1985; Lin and Lai 2008).

UK construction firms must employ a long-term perspective and realise the ways the industry is changing, and that acting now will ensure long-term survival. This research suggests that companies can address problems with corporate culture alongside stakeholder management in future given the clear links that have been established.

LEGAL AND REGULATORY ISSUES CHALLENGING THE PAKISTANI CONSTRUCTION INDUSTRY

Khalid M. Malik[1], Syed M. Ahmed, PhD[2], and Jodi J. Farrington, PhD PE[3]

ABSTRACT

The Pakistani construction industry suffers many of the same pains as that of a developing country. Corrupt governmental involvement and lack of regulatory constraints allow ill-qualified consultants and contractors to structure the industry to suit their purposes. To continue leveraging on domestic opportunities and competing in the global marketplace, Pakistani construction industry players need to address these challenges. Improvements need to be implemented by all parties along the entire construction industry value chain for lasting transformation to occur. The absence of a strong regulatory environment and authority is a problem that requires priority attention. Structurally weak legal and regulatory framework acts as a deterrent for attracting qualified consultants and contractors. To present a construction opportunity that will appeal to ethical and competent companies of both national and foreign ownership the Pakistani construction industry must provide an improved business environment.

Keywords: business, ethics, legal, Pakistan, regulations.

INTRODUCTION

This paper is founded upon the findings of a study performed by NED University of Engineering and Technology and Florida International University. The scope of the study was targeted toward identifying the key issues related to – and developing a strategic model for improvement of – construction project management framework in Pakistan, the findings of the study were more concentrated on identifying the gaps in construction project management education, research and practice in the industry. However, while diagnosing these specific issues, a number of macro-level industry issues in relation to the overall business and operational environment of the construction industry of Pakistan, in general, were also identified and noted. Two of the authors of this paper have an in-depth knowledge and understanding of the Pakistani Construction Industry through many years of work experience and consulting.

[1] khalidmalikz@hotmail.com
[2] ahmeds@ecu.edu
[3] farringtonj@ecu.edu

Of the multitude of macro-level topics revealed those listed below will be discussed herein:

- Construction industry business environment
- Construction industry regulatory environment
- Construction industry legal environment
- Ethical behaviors in the construction industry

To continue leveraging on domestic opportunities and competing in the global marketplace, Pakistani construction industry players need to address these challenges. Improvements need to be implemented by all parties along the entire construction industry value chain for lasting transformation to occur. Therefore, in addition to contractors all of the other participants in a project such as public clients, approving authorities, consultants, and other stakeholders must be involved in this transformation.

Construction Industry Business Environment

Political interference, corruption, transparency, and security issues are among the major impediments to the growth of the construction industry in Pakistan. Additionally, the lack of regulatory reforms, inadequate government planning, cumbersome policies and weak client agencies are responsible for many of the problems faced by Pakistani contractors. All of these factors contribute to the poor business environment and serve to multiply the transaction costs of doing business.

Disproportionately cumbersome business processes such as land acquisition; obtaining clearances; external agencies processes; funding and payments; cost escalations; changes and modifications; and, final certifications serve as enormous obstacles for companies trying to enter the industry. Even established businesses face difficulties in carrying out these project cycle activities.

There is no restriction on entry into construction by unqualified players, which further results in low quality and productivity; serving as a disincentive to the qualified professionals. Compound this with the nearly non-existent practice of black-listing and eradicating poor performing contractors/consultants from the available pool causes the problem to appear to outsiders as insurmountable.

A further detriment to the growth of the construction industry in Pakistan is that the industry is dominated by a few construction and consulting firms who subcontract an appreciable portion of their work to smaller contractors. Generally, the size of these subcontracts does not appeal to foreign contractors and consultants, hence, competition is scarce. Additionally, specialty contractors with adequate skills, manpower, equipment and tools in the fields of electrical, mechanical, HVAC, etc. are largely limited.

Pakistan is a high risk country in which the owners' practice to accept low bids by local (albeit poor performing or unqualified) consultants and contractors discourages foreign consultants and contractors from competing in the market.

 ISBN: 978-1-84219-840-7 .

Construction Industry Regulatory Environment

Construction, engineering and consulting organizations in Pakistan are subjected to three types of registration which are:

- Registration for the legal entity of the business upon its formation, followed by the requirement to submit annual/periodic reports;
- Registration with the official engineering body: Pakistan Engineering Council (PEC), requiring periodic renewal of registration and
- Registration with client agencies

In the case of registration as a legal entity, the submission of annual/periodic returns applies only to incorporated business entities such as limited liability, public or private companies. Other registered entities, such as registered partnerships and sole proprietorships do not have a requirement for annual returns. In registration with PEC, the periodic renewal plays a limited role, in so far as regulation is concerned, and registration requirements with the client agencies vary from client to client. Apart from the above, other associations which exist for the construction and consulting organizations mainly provide a forum and voice for their members, but cannot be considered as part of the regulatory framework of the construction and engineering consulting industry.

The PEC is however a formally recognized legal body which plays the role of a regulator for the industry, ensuring that minimum criteria are met for initial registration of an organization (construction contractors and consultants) and those criteria are maintained to enable yearly renewal of registration. A participating construction or consulting organization is required to keep its registration with PEC up to date. Although PEC is the official body for the industry, its role as a regulator is not dynamic or effective. PEC is not capable of monitoring projects and activities, their performance, adherence to professional and ethical standards or quality of construction materials used or application of technical skills on a project. There exists no form of continuous reporting or verification mechanism which should be in place for enabling such continuous monitoring.

Regulation of the construction and engineering consulting organizations is hence weak if not altogether absent, and in the absence of an effective regulatory body the owner plays the role of a regulator to a great extent through flawed and one sided contract documents. At times, in addition to client, several other government agencies and “committees” (such as the Chief Ministers’ inspection team) also indulge in acting as regulators. The client can, in the short to medium term and until such time as an effective overall regulatory environment develops, play its de facto role of a regulator in a more positive manner, provided that the relationship between client, “The Engineer” (consultant), and the contractor is honored as laid down in the FIDIC and PEC standard contract documents in letter and spirit. Adding the role of Construction Manager as an entity for professionally managing the project in its entirety is a dire need. Strengthening of the PEC or establishing a separate regulatory body is an option, which should be explored.

Suggested Steps to Improve the Regulatory Framework

1. PEC, being the primary regulatory body, should be more proactive in developing the industry.
2. PEC's capability needs to be enhanced on the following aspects: monitoring projects and activities, their performance, adherence to professional and ethical standards or quality of construction materials used or application of technical skills on a project. Continuous reporting or verification mechanisms need to be in place for enabling continuous monitoring.
3. The client can, in the short to medium term and until such time as an effective overall regulatory environment develops, play its de facto role of a regulator in a more positive manner, provided that the relationship between client, "The Engineer" (consultant), and the contractor is honoured as laid down in the FIDIC and PEC standard contract documents in letter and spirit.
4. Added role of construction manager as an entity for professionally managing the project in its entirety is a dire need.
5. Strengthening of the PEC or establishing a separate regulatory body is an option, which needs to be explored.
6. Current PPRA rules also support lowest bidder selection. This indicates that a lot of work is needed to streamline procurement rules and practices as well develop institutional capacities to implement procurement rules.
7. Granting "industry" status to the construction business has had no impact as without corresponding support from financial/lending facilities and without the implementation of reforms, no positive results are possible.
8. Audits are not concurrent, and delayed audits create opportunities for corruption. The role of auditors and the audit procedures need to be re-defined.
9. The only criterion emphasized in the regulations available is price competition and no provision is made to ensure the quality and safety of work being delivered. Hence there is a dire need to revise the regulations.
10. The role and mandate of institutions such as the PEC should be clarified and be made devoid of conflicting agendas as both a representative of the profession and an agent of the government.

Construction Industry Legal Environment

With multiplicity of contract forms, varied dispute resolution mechanisms, lack of willingness of parties involved to honor the awards, and no effective implementation mechanism in practice, disputes, in most cases, end up in courts of law and remain unresolved for long durations.

The Pakistani construction industry has tried to implement an ad-hoc arbitration process. However, the process has some major shortcomings that include:

- No provision of specific rules and requirement for parties to sign an agreement regarding the rules to be followed
- No provision for a neutral body to administer and supervise Arbitration
- No quality control of Arbitrator's qualifications and expertise and an obvious lack of close supervision/monitoring of arbitrator's progress
- No assistance available in managing Arbitrator's fees, and any administrative support.

One of the major reasons attributed to the poor effectiveness of the Ad-hoc Arbitration process is that at the time of signing the arbitration agreement, the owner often insists on having arbitrators from among its own serving or retired corporate officers or a panel with which it has some direct or indirect association. While this works in a large number of cases where the real intent of both sides is generally to reach an agreement, this also provides grounds for resorting to judicial remedies after the award is given.

Even when a settlement is reached through the arbitration process there is an increasing tendency to appeal on the grounds of "misconduct" on the part of arbitrators. Claimants particularly take the view that the arbitrator's decisions are not being approved by any responsible organization. This has added to the delays in the arbitration process which are increasingly resulting in time and cost overruns of projects.

Another grey area pertains to non-availability of clearly defined eligibility criteria and code of ethics with the appointing authority. Eligibility criteria for arbitrators are not fully transparent and do not follow a defined code of conduct.

Legal council needs to become involved to transform the ad-hoc arbitration system to one with credibility. At the least, the process must be modified to establish uniform requirements for qualification of arbitrators as well as instituting a method of establishing an unbiased panel.

Suggestions to Improve the Legal Framework

1. Construction Industry being the largest asset creator and second largest component of the economy having unique dynamics of business it is crucial that disputes be resolved speedily to minimize the business losses and capital blocked due to delayed and Ad-hoc process of dispute resolution.
2. The need has been widely felt to develop and set up in position the Institutional frameworks which can effectively tackle the hard-care problems of time and cost of the arbitration proceedings. The main objective for such an effort is to develop and place in position an Institutional Arbitration system, which would provide the following:
    a. appointment of arbitrators from the International and National or Regional panels,
    b. giving time commitment with a view to conduct arbitrations in an expeditious and cost effective way
    c. ability to act for conducting an audit for possible conflict,
    d. appointing an institutional appointee to execute institutional code of ethics,
    e. and providing a code of ethics for an Arbitrator focusing on impartiality, transparent communication, agreement on fees, and confidentiality.
3. A corrective measure needs to be taken to ensure the following:
    a. Laying down the eligibility criteria for nomination of arbitrators.
    b. Laying down the work ethics for nominated arbitrators, and setting up an implementation mechanism.
    c. Drawing up and adopting the arbitration and dispute resolution mechanism.

   d. Notifying and embodying the approved mechanism as a part of Standard Contract Conditions.
4. It is proposed to constitute a Construction Industry Arbitration Association (CIAA), which may operationalize these recommendations.
5. The CIAA will be entrusted with the task to articulate the following, in particular:
   a. Arbitration under Institutional rules formulated by Institution and revised periodically based on user feedback.
   b. Providing a panel of accredited Arbitrators based on selection criteria to maintain quality and standards and code of ethics/conduct.
   c. Management of Arbitrator's fees
   d. Monitoring and supervision of progress of case
   e. Arrangement of logistics, facilities and services for hearing.
   f. Controlling quality of Arbitrators,
   g. Maintaining a close supervision and monitoring of arbitrator's progress
   h. Providing administrative support for the whole process.

Ethical Behaviours in the Construction Industry

Corruption and transparency issues are the major challenges the government has to address in order to develop the capacity to improve the country's image. Implementation of FIDIC guidelines and contracts in letter and spirit is considered by industry participants to be essential for helping solve such problems.

Corrupt practices, which are a bane in the overall environment but over time have come to be accepted as 'necessary' and to be included if a project is to be won and then delivered with minimum hindrances. Offering bribes during the project lifecycle has become institutionalized. These practices cannot be called business processes but are an integral and unavoidable reality of the current business environment. These include unwritten procedures and fixed financial costs and charges for procedures such as; obtaining successful pre-qualification; having an audit objection cleared or expedited; obtaining timely approvals of work and release of payments; mobilizing the police to assist when needed; and for getting customs to give a favorable ruling of the duties and taxes on imports.

CONCLUSIONS

Generally, the contractors and the business environment in developing countries also tend to be under developed. Given the opportunity, they can overcome their inadequacies, but they cannot easily change the environment. The challenges being faced by the industry in developing countries include lack of long-term vision and planning for the industry; fluctuations in work load; defective contract documents; corrupt contracting procedures; and, unfair competition from state-owned contractors and consultants.

The structure of Construction Industry in Pakistan is highly skewed and characterized by small number of large construction companies, followed by very few medium level companies, and then followed by a very large number of small and petty contractors. It is ironic though, that the companies belonging to large segment in domestic context are also small when compared with those having International presence.

If the massive task of construction industry improvement has to be carried out, concerted efforts have to be made by the government under an institutionalized framework to change the skewed structure of construction industry, infuse better technology, further construction labor welfare and increase productivity and capacity of construction industry in Pakistan.

As the first step, the following initiatives need to be taken, for institutionalizing the framework that would improve the construction industry on strategic basis.

1. A Construction Industry Review Committee (CIRC) needs to be formed to comprehensively review the current state of the construction industry and to recommend improvement measures. The report to be submitted by the committee should outline improvement measures covering the whole spectrum of construction activities to uplift the quality and cost-effectiveness of the industry.

2. A statutory Construction Industry Development Board (CIDB) encompassing all key sectors should be formed to promote the culture of self-regulation in a market-driven environment. As an umbrella organization, the CIDB would be responsible for spearheading reforms and sustaining momentum to achieve continuous improvements across the construction industry.

The absence of a strong regulatory environment and authority is a problem that requires priority attention. Structurally weak legal and regulatory framework acts as a deterrent for attracting qualified consultants and contractors.

Finally, a dispute resolution process that has legitimate regulations as well as ethical and unbiased procedures will serve to encourage confidence in Pakistan's construction industry.

Abstract:
It is now almost a Century since the concept of subsidiarity in the law of unjust enrichment was coined. Some jurisdictions have enacted it in their Civil Codes while others apply it to a variable degree even if not enacted in the Code or not officially sanctioned in their jurisprudence/case law. This article revisits the concept once again and challenges some of its theoretical foundations and its unqualified application in the law of unjust enrichment as a whole. Using South Africa and Brazil as main references, but extending the analysis to common-law jurisdictions, it explores the extent and limits of the applicability of such concept in claims arising from the built environment context by analysing the interaction of the subsidiarity rule or (otherwise) with the defence of change-of-circumstances/loss of enrichment where a legal system directly or indirectly sanctions or aspires sanctioning a general principle against unjust enrichment. It concludes that in three party cases subcontractors may be able to use enrichment law against owners to obtain an adequate remedy.

Key Words:
Contract and enrichment, subsidiarity, unjust enrichment.

1 Introduction

Placing special emphasis on claims arising from subcontracting scenarios in the built environment, this article re-examines the subsidiarity rule in the law of unjustified enrichment.[1] In essence, the subsidiarity rule precludes a free choice of actions between enrichment and contractual claims or other legally recognized claims. The rationale for such a rule is, inter alia, to prevent subverting the legal order, to safeguard the *paritas creditorum* rule in cases of intervening insolvency and to direct the plaintiff to the proper claim.[2] The paper argues that the direct and unqualified application of the

[1] The use of 'unjust' and 'unjustified' enrichment terminology: The concepts are not interchangeable. I have discussed their differences elsewhere in my works. But in this article they are used interchangeably whenever they refer to the subject as a whole, that is to say, whenever common-law would use 'restitution' or 'unjust enrichment' I refer to it uniformly as 'unjustified enrichment' for elegance sake in reading.
[2] Avoiding a concurrence between contractual and enrichment actions in such scenarios strengthens the legal system by preventing plaintiffs who concluded bad bargains from circumventing their *cum causa* claim and pursuing a more

subsidiarity rule (if a legal system officially sanctions it), or its indirect application (where the rule is not officially recognized but nevertheless applied), often leads to incongruent results.

The discussion approaches the issue from South African and Brazilian law[3] perspectives. Brief references are made to the Franco-Italian treatment of the problem for pioneering the concept of subsidiarity in its most reported forms. An overview of the common-law treatment of the rule is also provided. The American approach is slightly singled out at some point. The analysis looks at the issue regardless whether the respective legal system expressly provides for a subsidiarity rule or not.

The re-examination of the rule starts with a conceptual analysis of subsidiarity in general. It proceeds with a practical assessment of the rule in specific jurisdictions, namely South Africa, Brazil and common-law jurisdictions, collectively termed in the paper as the Anglo-American approach. The study culminates by revisiting the roots of this old concept and re-assesses the working or otherwise of the rule in the South African case *Palabora Mining Co v Coetzer*[4] as illustration. An underlying idea that permeates the discussion is the question whether the recognition of a general principle against unjustified enrichment (or the aspiration to that aim[5]) in a legal system impacts on the operation of this rule. If it does, the question is asked whether the rule has any effect on the change-of-position defence.

2 Conceptual Analysis

2.1 What is generally understood by subsidiarity?

At its simplest form, 'subsidiarity' in legal discourse means that two principles or doctrines are in a primary-secondary relationship. It may also mean that one principle or doctrine is constrained in the presence of the other;[6] or simply that there ought not to be a concurrence between two subject matters, because the existence of one renders the other unnecessary or undesirable.[7] However the precise connotation given to the notion

rewarding claim. Jacques du Plessis expresses this scenario with an analogy of a plaintiff "**A**" having someone's cake and eating it by enjoying both a contractual claim against "**B**" (their contractual partner) and an enrichment claim against the third party, "**C**" (see Jacques du Plessis, *The South African Law of Unjustified Enrichment*, (Juta Publishing 2012) 302).

[3] The Brazilian approach is assessed through the analysis of the provisions of Articles 875-886 of the New Brazilian Civil Code of 2004.

[4] (1993) 3 SA 306 (T).

[5] See Niall Witty and Daniel Visser, 'Unjustified Enrichment', in Reinhardt Zimmermann, Daniel Visser and Keith Reid (eds), *Mixed Legal Systems in Comparative Perspective: Obligations and Property in Scotland and South Africa* (2004) 366-98; CM Jooste 'Compensation for Improvements by Tenants in South African Law' in Eltjo Schrage (ed) *Unjust Enrichment and the Law of Contract* (Kluwer 2001) 257-274.

[6] Here the basic principle that is applied is that the specific rules concerning one doctrine take precedence over the general rules concerning the other: Expressed in the Latin version we say: *lex specialis derogat legi generali.* However, see Lionel Smith in David Johnston & Reinhardt Zimmermann (eds), *Unjustified Enrichment: Keys Issuesin Comparative Perspective,* (CUP 2002) 610, commenting on the limits of such an approach in understanding the subsidiarity of unjustified enrichment.

[7] See for example the position advanced in English law in *Pan Ocean Shipping Ltd v CreditCorp Ltd* [1994] 1 All ER 470 (HL) 473-474 where Lord Goff said: "there is a contractual regime which legislates for the recovery of overpaid hire. It follows that, as a general rule, the law of restitution [unjust enrichment] has no part to play in the matter; the existence of the agreed regime renders the imposition by the law of a remedy in restitution both unnecessary and inappropriate". For subsidiarity in Scots Law see among other, Martin Hogg *Obligations* 2ed

dependents on the legal system that uses it. It also depends on the specific circumstances in which the term is used, and how it came to be used in that legal system. Inasmuch as legal systems formulate their legal doctrines and principles differently, so will vary their understanding of subsidiarity. Therefore, it cannot be assumed without more that the concept of subsidiarity means the same thing in all legal systems or even that its use in a particular legal system is necessarily an unequivocal one.

Some commentators see in subsidiarity the expression of the ordering of the private law itself. They argue that it reflects the values and commitments of a liberal society. The drive of a liberal tradition, which accords primacy and maximization to individual autonomy to citizens, requires subsidiarity of one 'branch' of the private law such as unjustified enrichment to serve protective interests. It empowers private parties to facilitate their private decisions.[8] Others simply state that subsidiarity is a technique of limiting the applicability of the general enrichment remedy. As such its exact meaning is a matter of legal policy.[9] Within this second reasoning falls another approach, advocated by Visser.[10] He says that the whole debate around subsidiarity in a particular legal system is nothing more than a discussion about the role to ascribe to unjustified enrichment doctrine. But Visser cautions that subsidiarity may not be the best way to delineate the scope of enrichment liability as the predominant trend in the world indicates.

Sometimes legal literature describes subsidiarity in two other different modalities:[11] 'weak subsidiarity' and 'strong subsidiary'.[12] Weak subsidiarity directs the claimant to the correct claim. Strong subsidiarity usually denies the plaintiff any claim. Deeper analysis reveals however that weak subsidiarity is nothing more than the relationship between two different claims. Strong subsidiarity on the other hand, is a relationship between legal dispositions or a set of rules. On this analysis subsidiarity, at its weakest point, denotes the subordination of one claim where another claim in fact offers the plaintiff a basis of recovery. At its strongest point, subsidiarity denies the availability of a claim because another claim is in principle available, even though on the facts it does not avail the plaintiff.[13] In some jurisdictions, these two modalities are described as

(Avizandum Publishing 2006) 241-247; Niall Witty, '*Transco v Glasgow City Council*: Developing Enrichment Law after *Shilladay*' (2006) 10 *Edinburgh LR* 113.

[8] See Epstein 'The Ubiquity of the Benefit Principle' (1994) 67 *Southern Cal. L R* 1369; Ross Grantham and Charles Rickett 'On the Subsidiarity of Unjust Enrichment' (2001) *LQR* 273, 293.

[10] Daniel Visser, 'Unjustified Enrichment' in Jan Smits (ed) *Elgar Encyclopedia of Comparative Law* (Edward Elgar Publishing 2006) 767, 772-773.

[11] CM Jooste, 'Compensation for Improvements by Tenants in South African Law' in Eltjo Schrage (ed) *Unjust Enrichment and The Law of Contract* (Kluwer 2001) 269-271 who thinks that there are at least four usages of the concept. The other types of subsidiarity that he mentions are 'practical' or 'factual' subsidiarity. Factual or practical subsidiarity according to the author consists in legal representatives usually framing their pleadings in the first place in terms of contract or delict, for instance, and only as a last resort, a final alternative claim – as it were an afterthought – dragging in the enrichment idea.

[12] Lionel Smith in David Johnston and Reinhard Zimmermann (eds.), *Unjustified Enrichment: Key Issues in Comparative Perspective* (CUP 2003) 596-597.

[13] Ross Grantham and Charles Rickett 'On the Subsidiarity of Unjustified Enrichment' (2001) *LQR* 273.

'concrete' subsidiarity and 'abstract' subsidiarity.[14] For 'concrete subsidiarity' is understood the situation in which one action (ordinarily an enrichment action) is excluded only when, in the circumstances of the particular plaintiff, the other action will in fact enable him to make good his loss. 'Abstract subsidiarity' denotes the situation in which the enrichment is excluded whenever in principle the other action is available, or could have been available even if in the particular case the plaintiff will derive no benefit from it.[15]

More recently, Visser[16] added a modified analysis to these modalities of subsidiarity just described. He argues that subsidiarity can be analysed in a tripartite enquiry. Ultimately this inquiry gravitates around the problem of whether a particular jurisdiction has or has not recognised a general enrichment action. If it has recognised one, the question then becomes is how it views or classifies it, and how concurrence of actions is perceived. In Visser's own words the threefold enquiry is as follows:

[Subsidiarity] is a complex notion and it could encompass several different questions, namely (a) whether a claim based on a general principle against unjustified enrichment should be subsidiary to specific existing actions (in systems where a general action is introduced alongside existing remedies); (b) whether, in the case of concurrence of actions, an enrichment claim must be seen as a last resort, or one which may be chosen as an alternative to, say, a contractual claim (provided of course the elements of both types have been shown to be present); and lastly (c) to what extent, if the nature of the concurrence takes the form of the claimant having a claim in contract against his contractual partner and a claim in enrichment against a third party, the claimant should be allowed to chose whom to sue'.

The first question is only relevant in jurisdictions where a general enrichment action is already recognised. The second is relevant to jurisdictions that contemplate introducing a general enrichment action. For these last jurisdictions, Visser suggests that the safest route is to recognise a general enrichment action which is subsidiary to the currently existing actions[17] because the unitary approach may not necessarily work.[18] The second question also underlines the debate what role a particular legal systems wants to give to the doctrine of unjustified enrichment. The third question is mostly relevant to the views on concurrence of actions between the different branches of private law or where actions are allowed to be pleaded in the alternative, especially where third parties are in issue. Hence, Visser concludes that

'if in a particular system the rule is that, once a claimant has exhausted the possibility of getting satisfaction from his contractual partner, he may institute an enrichment action

[14] This is the Italian position. Netherlands also had something similar. See Eltjo Schrage 'Unjustified Enrichment: Recent Dutch developments from a Comparative and Historical Perspective' (1999) *Netherlands International Law Review* 57-87.
[15] Barry Nicholas, 'Unjust Enrichment and Subsidiarity' in *Studi in Memoria di Gino Gorla, Vol III* (1994); Jack Beatson and Eltjo Schrage (eds) *Cases, Materials and Texts in the Law of Unjust Enrichment* (Hart Publishing 2003) 428.
[16] Daniel Visser, 'Unjustified Enrichment' in Jan Smits (ed) *Elgar Encyclopedia of Comparative Law* (Edward Elgar Publishing 2006) 767, 771-773.
[17] This view reflects the approach followed by the Quebec Civil Code and to some extent the structure reflected in the new Brazilian Civil Code to which I will refer later in this paper.
[18] This is mostly true of the German law treatment of its provisions in articles §§ 812- 822 of the BGB.

against a third party on the basis of unjustified enrichment, one has a situation of true subsidiarity. If however, a jurisdiction allows only one of the actions, that action is not subsidiary to the other possible action, but alternative. This is the province of multiparty enrichment'.

For the aforesaid it is obvious that the precise understanding of the concept 'subsidiarity' can only be captured if it is analysed in the context in which it is used.

Before I consider the concept in the specific jurisdictions mentioned above, some illustrative diagrams depicting different enrichment scenarios are in order.

A does work for B on C's premises.

A is fully paid by B. C evicts B

with no compensation

Fig.3

C contracts with B for a building Project. B subcontracts it to A. In turn A duly performs the building work on B's behalf on A's land. B goes insolvent. A sues B for recover of benefits conferred on C at C's expense.

Fig.4

C engages B to Build for him for $200.000. B does substantive work, but he does not complete it. C engages A to finish the work and pays him $50.000 A is enriched at B's expense for $150 000

Fig. 5

C engages B for building services. B subcontracts the work to A. A sends his own subcontractor D to do the work. D does the work and incurs. expenses. C is unaware of this chain. B becomes insolvent and D is not paid.

Fig.6

C engages B for a work. B subcontracts the work to A. A in turn uses two specialist services provided by D and E. D does the work on C premises on C's premises using own resources not agreed with A but E does so in agreement with A. B who has engaged A goes insolvent. A is clearly enriched at expense of D and E through services subcontracted by A.

2.3. The Operation of the subsidiarity rule in specific jurisdictions.

2.3.1. The South African approach to subsidiarity rule.

The notion of subsidiarity in the South African law of unjustified enrichment is virtually unknown.[19] As the law now stands, the basic approach is to allow a plaintiff the freedom of choice between alternative remedies. This in essence amounts to concurrence of contractual and enrichment remedies, or probably with any other area of the law. However, such freedom of choice is not so wide open in practice. Each factual scenario is to be evaluated on its own merits. A general distinction occurs between situations involving only two parties and those involving more than two parties. For example, in *ABSA Bank (Pty) Ltd v De Klerk*[20] the judge held that where 'the plaintiff has requested judgment on the alternative claim, the choice of relief lies with the plaintiff. The law does not compel the court to exclude the alternative claim merely because the plaintiff made the *conditio indebiti* its main claim.

A closer look at other South African decisions reveals generally two scenarios:

Firstly, where two parties are involved the choice of remedies lies with the plaintiff. But that choice may be curtailed for what I call 'an internal subsidiarity'.[21] The *condictiones* generally preclude the claimant to institute freely the *condictio* of his choice because the elements of each *condictio* are different. Also different requirements apply to each *condictio*. If a claimant is entitled to a relief under *condictio indebiti* he may not claim his relief under the *condictio sine causa*. Despite inconsistency in some cases, this is the prevailing attitude of the courts. In *Govender v Standard Bank,*[22] the Court held that a formalistic approach should be avoided where possible. 'In some cases it is necessary to classify the cause of action; in others where no issue turns upon classification of the cause of action, a plaintiff need not place a label upon this case. If he can show a prima facie case for a relief, it is not necessary for him to commit himself in advance in his pleadings to one form of action to the exclusion of another'. But later the judge notes that 'the *condictio sine causa*, in the special form (*specialis* as opposed to *generalis*) may be brought where the *condictio indebiti* is inappropriate to the case. Indeed, it cannot be brought where the *condictio indebiti* applies to the case'.

Secondly, where three parties are involved the situation is wide open. In some instances free choice and concurrence of actions will readily be allowed. In others such choice will be curtailed for the sake of internal consistency of the legal system. Such an

[19] The editor of chapter seven in Jack Beatson and Eltjo Schrage (eds.) *Cases, Materials and Texts on Unjustified Enrichment* (CUP 2003) 424 is puzzled why the issue is not discussed at all in South African law. He notes that that might be the case because the question of the subsidiarity of the enrichment-claim plays a more important role in jurisdictions which acknowledge a general claim than those that stick to the older specific remedies. And South Africa is still one of the few jurisdictions sticking to the piecemeal older Roman law remedies. However, the learned editors may have overlooked a recent case in the Cape Provincial Division (Cape Town) that has done remarkable survey on the extended *actio negotiorum gestio* that highlights cases in which an analogous approach to the *actio de in rem verso* is present – *ABSA Bank Ltd t/a Bankfin v Stander t/a Caw Paneelkloppers* (1998) 1 SA 939. But see Jacques Du Plessis, *The South African Law of Unjustified Enrichment* (Juta 2012) 298-306.

[20] (1999) 1 SA 861 (W).

[21] By implication, the other not mentioned is considered 'external subsidiarity'. By 'internal subsidiarity' I mean the exclusion of the other action within the same branch of law (in *casu* within unjustified enrichment) and 'external subsidiarity' in relation to the other branches of law (e.g, contract, delict (tort), property, etc).

[22] 1984 (4) 392 (CPD) at 396D-E.

approach can be inferred from various dicta in the cases. For example, the Supreme Court of Appeals in *Bowman*[23] case inter alia, held that the principles underlying the *condictio* (*condictio indebiti* in casu), are not immutable. In principle, a party is entitled to rely on the application of the *condictio indebiti* by analogy'.[24] The rules of the *condictio* are also not identical for all situations and there is scope for deviation, for instance where deceased or insolvent estates and the like are concerned.[25]

Thus, where third parties are involved, or where A tries to recover from C that which B has paid to C, there is a possible subsidiarity rule (or otherwise) in South African law. Ulpian in the *Justinian Digest* 12.6.5 mentions that 'there is nothing new about one person recovering with the *condictio indebiti* what another has paid'. It is my view that the same dictum would apply where other *condictiones* are involved if the facts so demand and justify it. Similarly, there is a rule in South African law stating that 'an unpaid or underpaid creditor of a deceased estate is entitled to recover from overpaid heirs and legatees, even though the payments have been made by the executor'.[26] He may do so under the *condictio indebiti* or *condictio sine causa*. This rule also seems to support the availability of an enrichment claim where third parties are in issue. The courts show some flexibility in practice. They extend the same rule of the unpaid creditor of a deceased estate to the case of a creditor of a dissolved company. Such extension enables a creditor to claim an overpayment from a shareholder who received more than he was entitled to.[27] This flexibility therefore points to a willingness to consider some sort of weakened subsidiarity in South Africa law.

This willingness is clearer in the 'subcontractor' cases. These cases however, are equally tricky because the decisions are not always easily reconcilable on strictly legal analysis. They invite more policy considerations. Visser and Miller[28] suggest that the anomalous outcome these cases expose could be addressed on a two-tier policy consideration. The first-tier is analogous to the process followed in delict (the law of torts), specially in pure economic loss situations.[29] The second-tier (which, with due respect, is unclear and very discretionary) dependent upon a positive outcome of the first-tier, is to 'determine whether, in the particular circumstances of the case at hand, a claim based on unjustified enrichment should be allowed'.[30] If the decision in this

[23] *Bowman, De Wet and Du Plessis NNO and Others v Fidelity Bank Ltd* 1997 (2) SA 35 (A) 43B-C.
[24] *Komissaris van Binnelandse Inkomte en 'n Ander v Villiers en Ander* 1994 (3) SA 203 (A) 333G-H; *Bowman v Fidelity Bank Ltd* (1997 (2) SA 35 (A) 40B-C.
[25] *Bowman, De Wet and Du Plessis NNO and Others v Fidelity Bank Ltd* 1997 (2) SA 35 (A) 43B-C.
[26] Idem at 40C.
[27] *Komissaris van Binnelandse Inkomte en 'n Ander v Villiers en Ander* 1994 (3) SA 203 (A) 330H-J. Here the Appellate Division effectively overruled an earlier decision in the Transvaal Provincial Division in *Rapp and Maister Holdings Ltd v Ruflex Holdings (Pty) Ltd* 1972 (3) SA 835 (T) that had held otherwise. In *Bowman, De Wet v Fidelity Bank* 1997 (2) SA 35, 43 D-E Harms JA held that 'depending on the circumstances of the case, A may claim from B that which C has overpaid, especially if C was acting in a representative or fiduciary capacity'. Hence, where liquidators acting in a joint capacity are impoverished to the full extent of an overpayment made to other creditors, where there has been an scheme of arrangement providing to pay such creditors, the liquidators in their capacity as joint receivers, become entitled to recover what was lost to the creditors, and the recovery would include any other party to the scheme whose money had been used to pay a creditor (*Bowman* 43E-F).
[28] Daniel Visser and Saul Miller 'Between Principle and Policy: Indirect Enrichment in Subcontractor and garage Cases' (2000) 117 *South African Law Journal* 594, 603-617.
[29] For an extensive exposition of the pure economic loss situations in the interaction between contract and delict, see Martin Hogg *Obligations* 2ed (Avizandum Publishers 2006) 108-194.
[30] Daniel Visser and Saul Miller 'Between Principle and Policy: Indirect Enrichment in Subcontractor and Garage Cases' (2000) 117 *South African Law Journal* 594, 606.

policy consideration is negative, the matter ends there. If however, it is positive, the courts should proceed, allegedly on *ad hoc* basis, to decide the actionability of the case based on the requirement of 'unjustifiedness' or that of 'at the expense of'[31].

A positive outcome on the first-tier, leaves further hurdles in place. These include the following questions: (i) how to reconcile the decisions with the possibility that allowing the subcontractor a claim may deprive the owner a possible defence against the main contractor? (ii) How to avoid the possibility that the subcontractor's claim could disturb the '*paritas creditorum*' rule against the owner in cases of insolvency? (iii) How to avoid the risk of placing the owner in the position of facing two potential successful claims by both the subcontractor and the main contractor? If the subcontractor is allowed to institute his claim, a later claim by the main contractor, as rightly Visser and Muller recognise,[32] could be met with the change-of-position defence for having given up the enrichment to the subcontractor.

Obviously, these difficulties strengthen the need for a general enrichment action that will allow the legal system to fully explore the contours of its defence of change of position.[33] If such a defence is conceptualised in two main versions, that is to say, in the reliance versions and the disaster version, an exit door to the difficulties posed by such cases could be conceptualised.

However, the clearest cases of subsidiarity in South African law arise in the so called 'extended *actio negotiorum gestio*[34] which is effectively an action *de in rem verso.*[35] Usually such action takes place in three party situations (see *Diagrams* Fig. 2 to 6 at 2.2 above) where A at the instance of B performs services for C without agency or something similar linking A and C. Sometimes A is unable to recover from B, where A was impoverished and C enriched as a result of A rendering services to C. In such cases A is sometimes allowed to claim directly from C on the basis of the latter's unjustified enrichment at the expense of B.[36] This situation involves an 'indirect' or 'third party'

[31] Idem 605.
[32] Idem 607.
[33] The defence of change of position in South African law is known as 'loss of enrichment'.
[34] The same action has historically been referred to with various names. It is sometimes called as *actio negotiorum gestorum contrar*ia, or according to some glossators as '*utilis actio negotiorum gestorum*'. Some Pandectists called it '*actio de in rem verso utilis*'. See generally Dion Van Zyl, *Die Saakwaarnemingsaksie as Verrykingsakie in die Suid-Afrikaanse Reg: 'n Regshistoriese en Regsergelykende Ondersoek* (1970) 87-88. For a similar study in Portuguese law, Diogo De Campos, *A Subsidiariedade da Obrigação de restituir o Enriquecimento* (Almendina Publishers 2003)) 55ff, also arrived at the same conclusions in his survey and uses in Pre-BGB Codifications such as the Prussian ALR 1794; the Austrian ABGB 1811, etc, which are however in contrast with the Codification Projects of Hessen 1842-1853 (art. 640ff), The Bavaria Project Code 1860 (arts. 902 and 750) and the Saxe Civil Code 1863 (arts. 1357, 791, 1519 and 1547) all of which either ignore the *actio de in rem verso* or the action is restricted to the cases of *negotiorum gestio* or severely curtailed.
[35] *Actio de in rem verso* is the concept mostly used in French law and generally refers to an enrichment claim not provided for under the French Civil Code, but it was sanctioned by the Cours de Cassation in *Boudier'*s case in 1892.
[36] See for example what Cloete J said in *Hubby's Investments (Pty) Ltd v Lifetime Properties (Pty) Ltd* 1998 (1) SA 295 (W) referring to the *Buzzard Electrical* case (1996 (4) SA 19 (A) 25H-26A): '[T]he Appellate Division characterized two of the situations which frequently arise in matters such as the present as 'type 1' and 'type 2' claims. The two types are as follows: The first arises when A effects improvements to the property of an owner, not pursuant to a contract with him but pursuant to a contract with B, and A then sues the owner for enrichment. The second type arises when the owner contracts with B for improvements to his property but B, instead of doing the work himself, subcontracts it to A and A sues the owner once he has completed the work' (at 297H-I). However the Appellate Division had already said in *Brooklyn* case [(1970) 3 SA 264 (A)] that 'Dit is byna vanselfsprekend dat verryking van die eienaar deur die besteding van nuttige of noodsaaklike uitgawes aan die saak, ten koste is van die persoon wat die uitgawes aangegaan het, en na my oordeel is dit, met betrekking altans tot die bestaan, al dan nie, van

enrichment. Huber in *Prelaetiones Juris Civilis*[37] based the action in these circumstances on equity and regarded it as subsidiary to a direct action based on contract. He says that '*ex aequitate contra alium dandam in subsidium actionem, quia quod de me ad te pervenit, hoc a te mihi rendid, bonum et aequum est*'.[38] The recent case *ABSA Bank Ltd t/a Bankfin v Stander t/a Caw Paneelkloppers*[39] echoes Huber's assertion above. The same approach also appears in *Knoll v SA Flooring Industries Ltd*[40] where De Villiers J criticising *Williams' Estate*[41] case, inter alia, said the following:

'[it] seems to me if a person, thinking that he was authorised to do so, that he had been engaged by the owner, *bona fide* does certain work to his house by which he has benefited – been enriched – in a certain amount it would be unjust for the owner to be enriched at the expense of the builder, and the latter could in equity claim the amount by which the owner has been enriched. That seems to me a perfectly good cause of action and, although one may bring it under the principles of *negotiorum gestor* (sic), it does not seem to me it is essential, for success in an action, to bring it in that principle. The equitable doctrine of unjust enrichment is wide enough to cover the facts in William's case to my mind'.

At this moment, however, there appear to be two conflicting decisions in South African law on the extended *actio negotiorum gestor: Gouws v Jester Pools (Pty) Ltd*[42] and *ABSA Bank v Stander.*[43] Both these cases were decided on appeal by two judges in their respective provincial divisions and are not the final word on the issues raised for all other provincial divisions. However, it is theoretically possible that *Gouws* case has been overruled by implication by the Supreme Court of Appeals in *Brooklyn House*[44] or at least by the rejection of the artificial distinction between an 'enrichment action' and 'enrichment lien' in *Buzzard*[45] *case*. If that is not the case, then the situation remains unsettled.

Academics on the other hand disagree on indirect enrichment claims in South African law. One group is keener to maintaining consistency and strict logic in the legal system.

---

so 'n retensiereg, nie ter sake nie dat die uitgawes aangegaan is ingevolge 'n geldige kontrak met 'n derde teen vergoeding'. Therefore, 'once the Appellate Division has recognised a right of retention in the first type of cases (*Brooklyn, JOT Motors*); and once the Appellate Division has declared that the distinction between right of retention and action is a distinction without a difference (*Buzzard* case), it must follow, as a matter of logic, that an action is also maintainable in the first type of case' (at 299C-D).

38 This text is translated as follows:"A subsidiary action must be given against the other because it is good and fair that that which you have received from me should be returned by you to me".

39 (1998) 1 SA 939 (CPD). In this case, Van Zyl J, said the following: '[I]n cases of indirect enrichment, recourse is had to the action arising from the *bona fide* management of another's affairs under the mistaken belief that they are the *gestor's* own. The varying nomenclature used to describe this action is irrelevant. What is relevant, however, is that it appears to operate as a subsidiary action, when a direct action against another party should not be available or effective. Equity then dictates that the *gestor* should not be unjustifiably impoverished and the *dominus* unjustifiably enriched as a result of the *gestor's* performance which has been the *dominus'* (at 946 C-D).

44 *Brooklyn House Furniture (Pty) Ltd v Knoetze and Sons* 1970 (3) SA 264 (A).

45 *Buzzard Electrical (Pty) Ltd v 158 Jan Smuts Ave. Investment (Pty) Ltd en 'n Ander* (1996 (4) SA 19 (A). The *Buzzard's* distinction was again referred to by the Supreme Court of Appeals in *Singh v Santam Insurance Ltd* 1997 (1) SA 291 (A).

The other group is more pragmatic and policy oriented. Among the first are De Vos[46] and Sonnekus.[47] This group basically contends that allowing indirect enrichment opens the door to subverting the legal order. Sonnekus' contention is that whenever there is any intervening contractual obligation to render performance, the relevant impoverishment and enrichment cannot be regarded as *sine causa* but it is always *cum causa*.[48] De Vos in turn objected to allowing such claims because they would, inter alia, conflict with the principle of *paritas creditorum* in case of intervening insolvency. If, for example, B (the enriched) should become insolvent and A (the claimant) would then have a choice between contractually suing the insolvent estate of B, on the one hand, or suing C (a third party) on the basis of unjustified enrichment, on the other. He contends that in the first scenario the claimant would only have a concurrent claim against the insolvent estate, while in the second scenario he would be able to claim the full amount owing on an enrichment basis.[49] This situation effectively subverts the legal order.[50] Among the second group are Honoré,[51] Van Zyl[52] (later a judge), Scholtens,[53] Visser[54] and Du Plessis.[55] Although for different reasons, either based on the presence of such an action in South African law by surveying the common law authorities and the South African case law (Hororé), or by a rigorous analysis of the requirement 'at the expense of' among others (Scholtens), or for equitable reasons, judicial expediency and judicial policy (Visser and Du Plesiss), all authors agree that unjustified enrichment has an 'equitable connotation'. As such it must be able to grant a relief where there is manifest injustice and no policy considerations militate against granting such a relief. Where, for example, it will be unjust and inequitable to deny A an action against C when it is clear that A has been impoverished and C enriched as a result of A's services or activity on C's property, and A would not have recourse against B, because B, for instance, has disappeared from the scene rendering any potential action against him or by him academic, justice and fairness certainly demand that there must be some recourse. In such a case to adhere to a rigid approach is inequitable. If a contractual action should be useless or academic, the plaintiff should not be allowed to suffer an irrecoverable loss and the defendant to derive an unassailable benefit for which he does not pay. The fact that, on the face of it, the claimant might not have (strictly) complied with the causal requirement should not, in the circumstances of these kinds of cases, deprive the plaintiff of an enrichment action.

In sum, although not expressly discussed under a specific heading, the issue of subsidiarity has been ventilated in South African law either through third party and indirect enrichment cases or through the discussion of the appropriateness or priority of one *condictio* over the other (or others), and the result is that policy considerations and other factors may dictate some departures from strict logic and formalism. In other words, concurrence of actions in contract and unjustified enrichment is recognised if policy considerations are not against granting the third party an action.

2.3.2. *The Subsidiarity rule in Brazilian law.*

Brazil, similarly to the Quebec *Code Civil*[56] and Portuguese *Codigo Civil*,[57] has now enacted a general enrichment action in the Civil Code of 2004 (articles 884-886). However the action for the *repetição do indevido* (reception of a thing not due (articles 878-883))[58] also continues to exist separately from the general enrichment action. But both actions fall under the heading 'unilateral Acts' (*Dos atos unilaterais*). Thus the nature of enrichment liability in Brazilian law as codified entails a general enrichment action alongside other claims of unjustified enrichment that apply only to particular fact patterns. Because this legal system provides more than one type of claims for unjustified enrichment, the way the provisions are structured reveals that a plaintiff is not allowed a free choice among these different types of claims, even where the facts of the case satisfy more than one claim. Under its dual structure, one type of claims is considered to be of a general nature while the other is of specific character. The law structured in this way, will more likely hold that the general claim will not be appropriate where the facts fit the claim for *repetição do indevido* even though the latter may not succeed.[59] The subsidiary character of enrichment claims is defended inter alia on the basis that it is the only way to prevent the judge, under the apparent cover of equity,[60] to fall prey to

[56] Québec Civil Code, articles 1493-1496.

[57] *Portuguese Civil Code*, articles 473-480. Article 474 provides 'Não há lugar à restituição por enriquecimento quando a lei facultar ao empobrecido outro meio de ser indemnizado ou restituído, negar o direito à restituição, ou atribuir outros efeitos ao enriquecimento' [There shall be no restitution by enrichment *sine causa* if the law provides to the impoverished another means for indenmization or restitution, or that negates him the right to restitution or that gives to the enrichment other results]. Note however that this subsidiarity in Portuguese law was vehemently opposed in the *Travaux Préparatoire* leading to the 1966 Civil Code, especially by Vaz Serra (in articles 721 of the 'Anteprojecto de Direito das Obrigações' [Project Draft on the Law of Obligations]. However, Article 474 of the Project that emanated from the Second Ministerial Revision, leaned towards the Italian Civil Code article 2042, to keep Portuguese law in line with Belgium law and French jurisprudence (See Antunes Varela *Das Obrigações em Geral* 10th Ed (Almendina 2000) 500). Up to 1970, Vaz Serra maintained his position that the subsidiarity of the unjustified enrichment introduced in the Code was not a secure principle (Annotation to judgment of S.T.J. (Supremo Tribunal de Justiça) of 6 January 1970 in *RLJ (Revista de Legislação e de Jurisprudência);* No. 104, 24).

[58] This is the French action of *réception de l'indu.*

[59] See for example a Canadian case decided under the Civil Code of the Lower Canada with similar structural provisions – *Willmour Discount Corp. v Vaudreil (City)* (1994) 2 SCR 210, 227.

[60] The exaltation of equity can for example lead a court to find a 'constructive trust' such as in the Canadian case *Pettkus v Becker* (1980) 117 DLR (3d) 257, where there would probably be none in many legal systems. There Dickson J for the majority in the Supreme Court held, inter alia, that 'the great advantage of ancient principles of equity is their flexibility: the judiciary is thus able to shape these malleable principles so as to accommodate the changing needs and mores of society, in order to achieve justice. The constructive trust has proven to be a useful tool in the judicial armoury…'. Then the judge referring to his previous case in *Rathwell v Rathwell* (1978) 83 DLR (3d) 289 applies the constructive trust in the unjustified enrichment case in the context of matrimonial property controversies (at p 273 ff). But Martland J, for the minority immediately warns: 'In my opinion, the adoption of this concept involves an extension of the law as so far determined by this Court. Such extension is, in my view, undesirable. It would clothe the judge with a very wide power to apply what has been described as 'palm tree justice' without the benefit of any guide-lines. But what test is a judge to determine what constitutes unjustified enrichment? The only test would be his individual perception of what he considered to be unjustified' (at 262).

arbitrariness. He would then transform the bench into an 'office of public assistance', instead of a court of law.[61] Thus, failing to make enrichment claims subsidiary, equates to allowing uncertainty to govern the law.

However various borderline problems that other legal systems tend to resolve under enrichment liability, such as why a transaction was declared invalid or the fundamental agreement that served as the base of the transfer of property has prescribed, etc, Brazil deals with them through the simple mechanism of nullity, rescission or through the contract itself.[62] Therefore this system accords maximum primacy to a contractual regime. It endeavours resolving most of the issues within the contractual realm as long as they have any contractual link real or apparent. This choice seems very narrow. However this choice seems to reduce litigation, promote finality and certainty, and encourages self-reliance. For Brazilians, a less restrictive approach to enrichment liability such as that of Germany and more recently the English approach are mostly seen as unsettling people's power to control their affairs through contract and gifts, and/or as opening the floodgates of litigation. That is so because every disposition of wealth is vulnerable to be subjected to a review with inquiries into the effects of legal transactions not only on the immediate parties but also on third persons and persons further removed. Whether these and other fears regarding the law of unjustified enrichment and the ambits of its defences are well founded, and to what extent justice is fully served under the narrow paths are issue that may need further analysis. For the time being, however, that is all that I have to say.

One problem that arises under current Brazilian enrichment law, is whether the now sanctioned 'general enrichment claim' which states in article 886 that the claim is subsidiary, also applies to the *condictio*-version of the claim. That is to say to claims arising under Articles 887-883 of the Brazilian Civil Code. That is so because those claims are not labelled as enrichment "*sem causa justa*" [senza justa causa]. A quick glance to article 886 would suggest so, because it says 'enrichment claim shall not lie if the law offers another remedy for the aggrieved party to redress his loss'.

2.3.3. *The Anglo-American approach to subsidiarity rule.*

The current common-law of unjust enrichment is very diverse. It varies greatly from jurisdiction to jurisdiction. In many instances there is little agreement. In some jurisdictions, especially in the USA, it is still called the law of quasi-contracts[63] with all

[61] Antunes Varela, *Das Obrigações em Geral* Vol. I (Almendina 2000) 507.
[62] Idem. 505.
[63] Louisiana Law, for example, following its Civil-law tradition, abandoned as recently as 1995 the '*Quantum Meruit*' as the basis for recovery in unjustified enrichment. It codified its main law of unjustified enrichment in article 2298. An history and explanation of Louisiana law is provided in Jeffrey Oake, Comment, 'Article 2298, The Codification of the Principle Forbidding Unjustified Enrichment, and the Elimination of Quantum Meruit as a Basis for Recovery in Louisiana' (1996) 56 *Louisiana LR* 873. A handful of other States call it the 'law of enrichment by impoverishment' whose elements are (i) an enrichment, (ii) an impoverishment, (iii) a connection between the enrichment and the impoverishment, (iv) absence of justification for the enrichment and impoverishment and (v) an absence of a remedy provided by law (for this view see generally Mark Gergen 'What Renders Enrichment Unjust?' (2001) 79 *Texas LR* 1927); others such as Lionel Smith in the Canadian context call it 'autonomous unjustified enrichment' (see Lionel Smith 'Restitution: The Heart of Corrective Justice' (2001) 79 *Texas LR* 2115, 2116); Andrew Kull on the other hand, leans more towards a civilian approach as he holds that the enrichment determination

the intricacies of that concept. Equity still prevails in the field, despite the enactment of the Restatement First of Restitution nearly 80 years ago and more recently the Restatement Third of Restitution and Unjust Enrichment[64]. Though they are becoming rare, some cases still hold that the three elements of unjustified enrichment are: '(i) a benefit conferred upon the defendant by the plaintiff; (ii) an appreciation or knowledge by the defendant of the benefit; and (iii) the acceptance or retention by the defendant of the benefit under the circumstances as to make it inequitable for the defendant to retain the benefit without the payment of its value'.[65] These expressions still mimic the elements of quasi-contract or implied contract theory. In Canada (excluding Québec), unjustified enrichment is based on three pillars, the third of which is enrichment without '*juristic reason'.* The remedy of constructive trust first sanctioned in *Pettkus v Becker*[66] is being extended beyond the realm of marriage. In such a context it is difficult to extract a unified concept of subsidiarity, if any, that covers to all common-law jurisdictions. However, it is encouraging (unlike in the South African law)[67] that the existing literature highlights certain instances in which an unjustified enrichment is subsidiary to other branches of the law,[68] although such view is not universally shared

---

is inescapably normative, for it is only possible to determine whether a person's welfare has been improved after establishing a baseline from which it can be measured, and the choice of the baseline is inescapably a normative question (Andrew Kull, 'Rationalizing Restitution' (1995) 83 *Cal. L Rev*. 1191, 1235-36). Opponents of the normative approach argue that all attempts thus far in common-law jurisdictions to try to systematize and understand the law of restitution as based in unjustified enrichment – i.e, the pivotal event triggering it 'is a state of the world' – the enrichment of D at P's expense – (an attempt to give the law a structure, like Tort, by organizing it around events that make enrichment unjustified (Seavy and Scott's *Restitution*, Goff and Jones treatise, Palmer's treatise, Birks' book) have thus far been forced efforts, for, they argue, in none of these works, is possible to find a conceptual apparatus that we would expect to find in a general body of law that takes the general form of the principle 'event *x* causing outcome *y* gives rise to an obligation of D, who as an agent of *x* (or otherwise responsible for event *x*), to make amends for *y*'. Such efforts, they conclude, lack a cause-in-fact theory and a theory of legal cause to connect *x* to *y* '. It even lacks a well-worked-out rules and standards of conduct to define *x* (*x* being an event from which any resulting enrichment of B would be unjustified). That is so because, in the law of Torts (delict), for example, the events are called wrongs and the proscribed result is injury. Therefore even if it were possible to say that the concept of enrichment by impoverishment makes the causal event of D's gain P's loss, it would still look somewhat odd to speak of P's loss as a causal event of D's gain, because though the causative event is the combination of gain and loss, what in reality this event causes is the obligation to make restitution'. The contenders however acknowledge one exception where the normative theory works: In situation where the occurrence of a non-consensual transfer from P to D is made an essential element of a claim for restitution [under the heading of enrichment by impoverishment], then it is possible to organise this part of the law around the causative event of a non-consensual transfer (see Mark Gergen 'What Renders Enrichment Unjust' (2001) 79 *Texas L R* 1927, 1951).

[64] ALI *Restatement Third of Restitution and Unjust Enrichment* in 2011) and the First *Restatement of Restitution* in 1937.

[65] See for example the following recent cases still applying the same concepts: *Great Rivers Co-op of Southeastern Iowa v Farmland Industries, Inc.,* 198 F.3d 685 (8th Cir. 1999) (applying Kansas law); *Planet Productions, Inc. v Shank* 119 F. 3d 729 (8th Cir. 1997) (applying Missouri law); *Oregon Laborers-Employers Health and Welfare Trust Fund v Philip Morris, Inc.* 185 F.3d 957 (9th Cir. 1999), cert. denied, 528 U.S. 1075, 145 L. Ed 666 (2000) (applying Oregon law); *University of Colorado Foundation, Inc v American Cyanamid Co.* 196 F.3d 1366 (Fed. Cir. 1999), cert. denied , 529 U.S. 1130, 146 L. Ed 2d *956* (2000) (applying Colorado law); *Media Services Group, Inc v Bay Cities Communications, Inc.* 237 F. 3d 1326 (11th Cir. 2001) (applying Florida law).

[66] (1980) 2 SCR 834. The same approach was also used in *Sorochan v Sorochan* (1986) 2 SCR 38.

[67] Daniel Visser touches the issue in passim in his Article 'Searches for Silver Bullets: Enrichment in three party situations' in David Johnston & Reinhard Zimmermann (eds.) *Unjustified Enrichment: Key Issues in Comparative Perspective* (2003) 452-456, and a short introductory note to the issue in chapter seven on the South African perspective in Jack Beatson and Eltjo Schrage (eds.) *Cases, Materials and Texts in Unjustified Enrichment* (Hart Publishing 2003) 486 simply observes that 'It should be noted, however, that the virtually free choice of remedies in South Africa exists only when there are two parties involved. The question whether one can choose between, on the one hand, a contractual remedy against one possible defendant and, on the other, and enrichment action against the other possible defendant in a three-corned situations receives a more cautious answer'.

[68] Lionel Smith 'Property, Subsidiarity and Unjust Enrichment' in David Johnston and Reinhard Zimmermann (eds.) *Unjustified Enrichment: Key Issues in Comparative Perspective* (CUP 2002) 588. (also available at

by common law writers. The late Birks, noted in passim that 'the fact that a misdirection of funds may involve both claims in unjustified enrichment and claims to compensatory or restitutionary damages in conversion should not distract. It is a common phenomenon. English law has recently reaffirmed that it tolerates concurrence, without insisting on separating the different causes of action by doctrines of priority and subsidiarity'.[69] Because different causes of action have different characteristics at common-law, it is for the plaintiff to choose the cause to plead. In short, Anglo-American law generally recognises a narrower notion of subsidiarity, albeit its strength varies from one jurisdiction to another.

Some general trends, however, can be deduced from the organization of the law itself. First, there is generally no requirement that a person seeking restitution must proceed directly against the immediate payee or transferee of the benefit rather than a third party whose title or interest derives from the transfer,[70] except in some well defined cases.[71] Therefore the law becomes flexible and recourse to subsidiary concept to limit liability is attenuated. Secondly, some rules nonetheless have an adverse effect on the generality principle of recovery of benefits transferred where it later transpires that there was some anomaly. For example, the existence of a contractual regime between the claimant and a third party may preclude restitution from the immediate payee/transferee.[72] Thirdly, a subtle subsidiarity arises where there are potentially claims in contract and unjustified enrichment (restitution). The rule that restitution for failure of consideration is only available where a contract was discharged for breach or frustration,[73] or otherwise held to be ineffective has similar effect. It gives primacy to the contractual regime (with its valuation benefit) and only gives unjustified enrichment a role in determining the parties' rights once their own contractual allocation of risk ceases to be effective.[74]

---

http://ouclf.iuscomp.org); Ross Grantham and Charles Rickett 'On the Subsidiarity of Unjust Enrichment' (2001) 117 *LQR* 273.

[69] Peter Birks 'Change-of-Position' in Mitchell McInnis (ed) *Restitution: Developments in Unjustified Enrichment* (Law Books Company 1996) 55; See also *Henderson v Merrett Syndicates Ltd* (1994) 3 WLR 761, the actual case where English law reaffirmed its tolerance of concurrence of actions.

[70] For example, we read in *American Jurisprudence* ((2003) 66 2d § 24) that 'the mere existence of a written contract governing the same subject matter does not preclude a *quantum meruit* recovery from third persons or non-parties so long as the other requirements for quasi-contract are met'. See also *U.S. v Applied Pharmacy Consultants Inc* 182 F. 3d 603 (8th Cir. 1999); *U S East Telecommunications Inc v U S West Communications Services Inc*. 38 F. 3d 1289 (2nd Cir. 1994).

[71] Among such cases is the rule that a non-compulsory payment to a creditor does not discharge the debt since that rule precludes a restitutionary action against the debtor and forces the payer to proceed against the creditor (e.g. on ground of failure of consideration).

[72] *Pan Ocean Shipping Co. v CreditCorp. The Trident Beauty* (1994) 1 WLR 161. This case concerned an attempt to recover benefits conferred on a person in the course of performing a contract with a third party. The owner of a ship chartered it and then assigned the right to payment of hire under the charter. The charter-party contained a provision for the repayment to the charterer of any hire paid for a period when the ship turned out to be off-hire. It was held that the assignee, to whom the charterer had made such payment, was not liable to the charterer, to repay the hire paid in contract or restitution. The liability to repay the hire in the charter-party remained exclusively with the party to the contract, the ship owner. For American law, see for example *R.B. Ventures Ltd v Shane* 112 F. 3d 54 (2nd. Cir. 1997) (applying NY Law); *Marple v Kurseg* 902 F. 2d 397 (5th Cir. 1990) (applying Louisiana Law); *Klein v Arkoma Production Co.* 73 F.3d 779 (8th Circ. 1996)(applying Arkansas Law); See generally 66 *American. Jurisprudence* §§ 24-26 (2003).

[73] Gerald McMeel *The Modern Law of Restitution* (Blackstone Press 2000) 130. The author also discusses modern criticisms of such a rule.

[74] Jack Beatson and Eltjo Schrage (eds.) *Cases, Materials and Texts in the law of Unjustified Enrichment* (Hart Publishing 2003) 426.

While that description applies to all common-law jurisdictions in general, the American experience is somewhat peculiar. The trend there in sub-contractors' cases, or in other three parties' cases in general, is not to favour liability. However, this general rule is really *prima facie* only. The rule is often qualified in practice either directly by judicial decisions, or academics in general doubt its unqualified application. The rule on subcontractors in most States is clearly captured in Dobbs Law of Remedies[75] as follows:

Rule 1: The subcontractor is generally not entitled to a restitution claim against the landowner. *Rule 2*: A subcontractor is however, entitled to enforce his claim against any funds still held by the landowner but which are owed to the general contractor.[76]

How should we read the rule as presented by Dobbs? Is really the general norm stated in rule 1 a clear-cut one? If read together with rule 2, it becomes clear that the rule in item 1 establishes a very limited principle. Reading both rules together shows that a plaintiff A in such scenarios cannot recover from C –the owner – if C has paid the main contractor. If on the other hand, C has not really paid the main contractor, then a claim based on restitution (or unjust enrichment) is clearly actionable. Under what conditions such an action is allowed in practice? There is no universally accepted idea in the cases. Generally, however, the courts use a three fold inquiry: first they pose the question as to whether the defendant (in most cases the owner) was in facts enriched. Secondly, if the answer is affirmative, then the following question follows: was the enrichment unjust? Thirdly, is there sufficient causal link between defendant's (owner) enrichment and the plaintiff's loss? In other words, is whether the defendant's enrichment is 'at plaintiff's expense.

In short, the position in American law is that subcontractors' enrichment claims against owners are allowed if the owner would benefit from the subcontractor, but there is no direct contractual relationship between the owner and the subcontractor. The mechanisms, however, how such claims are raised are not very clear.

3 Revisiting the roots of an old concept. How does *Palabora* case fit in?

Current multiple interpretations and models of subsidiarity ranging from those based on mere policy considerations to philosophical, political and historical reasons, sometimes have little to do with legal reasoning. Examining closely the various approaches reveals that they engender more confusion than clarity. The old French cases that gave birth to subsidiarity rule did not always do so with convincing reasons. They often produce more inconsistencies than clarity.[77] The judgments[78] in which the *Cour de Cassation*

[75] Dan B Dobbs, *Dobbs Law of Remedies* Vol 3 2nd Ed (West Publishing Co 1993).
[76] Dan B Dobbs *Dobbs Law of Remedies* Vol 3 2nd Ed (West Publishing Co 1993) 470.
[77] Here are just a few conflicting reasons advanced for the concept and based on the same authorities: (i) Demongue says that «la seule raison en faveur du caractère subsidiaire est celle de l'économie des moyens, il faut éviter l'action d'enrichissement quand on a une voie plus simple» [the only reason in favour of subsidiarity is that of economy of means; it is necessary to avoid an enrichment action if there is a simpler way to achieve the result] ; (ii) Renard denying its subsidiarity character, but explaining the same cases (below *arrêts* de 12.5.1914 and 2.3.1915) by means of the causa requirement says: 'c'est plutôt pour des raisons de fait sans rapport avec la nature de l'action *de in rem*

says expressly that the plaintiff may not have at his disposal '*pour obtenir ce qui lui est dû aucune action, naissant d'un contrat, d'un quasi-contrat, d'un délit ou d'un quasi-délit',*[79] are usually considered as the 'authoritative' remote pronouncements for the notion of subsidiarity. However, these judgments may also be exhaustively explained without any appeal to any other action. Arguments were advanced that in the first judgment an appeal is made to enrichment because of performance. In the second judgment the enriched party enjoyed the enrichment as a result of his position as a creditor.[80]

Certainly the formula used summarises all the requirements as formulated in Aubry and Rau and taken over in *arrêt Boudier* and the *Cour de Cassation* in these two *arrêts* above (*Clayette* and *Briauhant*). The judgments intended to accord a certain kind of subsidiarity to the actio *de in rem verso*. But what kind of subsidiarity is it? The formulation adopted allows different interpretations. For example, explanations in French texts on Obligations in general[81] and specifically those referring to Aubry and Rau such as Bartin's work[82] do not offer any certainty on the issue. Bartin's opinion is that Aubry and Rau's formula can be interpreted in three different ways: Firstly if another action exists, whether against the same person or against another person, there can never be an *actio de in rem verso*. Secondly, if such action exists, there can only be an *actio de in rem verso* if this action has become legally ineffective. Thirdly, except in the case mentioned under the second possibility, the *actio de in rem verso* is admissible, if the other action has become practically worthless due to the insolvency of the debtor. Bartin leaves here the choice between the views given open to the reader. He does however point out that, in his view, an enrichment action is excluded, if the impoverished party has a contractual action at his disposal. The same threefold interpretation appears in Flour and Aubert.[83]

In South Africa Visser also advocates a threefold enquiry in subsidiarity understanding, albeit slightly different from Bartin's interpretation above. Again, Jooste's analysis notes four approaches to this notion, adding yet another difficulty. The first three notions of subsidiarity in Jooste's[84] assessment largely correspondent to the elements discussed above. They simply reflect the Franco-Italian approaches. But Jooste adds a

---

verso qu'on peut parler du caractère subsidiaire de l'action'. And explaining the same cases on the basis of *causa* requirement concludes: 'la situation contractuelle exclut inter partes l'action *de in rem verso* pour tout deplacement patrimonial ayant sa source dans le contrat même' [It is rather for reasons that have nothing to do with the nature of the *actio de re in verso* that one may speak of the subsidiary character of the action'; (…) 'a contractual situation between the parties excludes the *actio de in rem verso* for any patrimonial shift whose source is the contract itself']. (See generally English translation of Marcel H Bregstein, Dissertation, *Ongegronde Vermogensvermeerdering* (PhD Thesis, Amsterdam (1927) 260-261) in Jack Beatson and Eltjo Schrage, *Cases, Materials and Texts in the Law of Unjustified Enrichment* (Hart Publishing (2003) 461-464.

nuanced interpretation borrowed from two Dutch scholars, Snijders and Hartkamp.[85] These scholars refer to a 'practical' or 'factual' subsidiarity which allows lawyers first framing their pleadings in contract or delict, for instance. Thereafter, as a last resort, pleading a final alternative claim – as if it were an afterthought – dragging in the enrichment idea. This in fact is nothing more than a procedural subsidiarity. Visser's approach also envisages such subsidiarity implicitly when he mentions his third leg with claims in the alternative.[86] Jooste however adds a fourth conception, which apparently is in contrast with the other three in that the previous ones are all framed in the negative. 'All of them determine when an enrichment is (at least not primarily) competent, but they do not tell what an enrichment claim can do'. Jooste's fourth 'subsidiarity' conception, however, is 'both theoretical and positive'. Theoretical because of it 'concerns with the taxonomic status of enrichment law within the entire legal system'.[87]

How does the case *Palabora Mining Co v Coetzer* fit[88] within this enrichment liability approach?

In brief, the facts of this case were as follows:

The plaintiff, Mr Coetzer had been employed by *Palabora Mining Co* (the Mine). The Mine provided him with rented personnel accommodation as part of his employment package. He was at some point dismissed by the Mine (allegedly unfairly so) and evicted from the leased premises. While in occupation of the leased premises, he had built a swimming pool with an apparently horrendous 'Blue Grotto' effect concrete superstructure. He now wanted compensation from the Mine for the alleged improvement to the premises.

The facts above clearly establish an enrichment. But is it an actionable enrichment? If the subsidiary rule just analyzed is recognized under South African law based on Roman-law tradition, such circumstances of improvement to another's property 'without their express consent', the claim would require the principal's express consent (which was lacking in the event). Alternatively, it would require, at least a 'tacit consent/ 'free acceptance/acquiescence' (in English terminology) (which was apparently the case, though uncertain). A third avenue is to argue that the expenses were such that he Mine as owner would have (been able) to make them themselves. What is then the most desirable approach?

For Jooste, *Palabora* case fits adequately into enrichment liability. This fact-pattern invites a general enrichment action to cure the defects in the system. That is so because as long as there is some sort of say, tacit consent the facts should be actionable.

[85] CM Jooste 'Compensation for Improvements by Tenants in South African Law' in Eltjo Schrage (Ed) (2001) 270.
[86] Visser says: 'If however, the jurisdiction allows only one of the actions, that action is not subsidiary to the other possible actions, but alternative' (Daniel Visser, 'Unjustified Enrichment' in Jan Smits (ed) *Elgar Encyclopedia of Comparative Law* (Edward Elgar Publishing 2006) 772). Though what Visser envisages here is objectively a substantive issue, it nonetheless raises the procedural issue, because for the alternative to be available to the claimant, it must be pleaded. That is what really a practical or factual subsidiarity means, although procedural rules may prevent it from being pleaded at a later stage.
[87] CM Jooste 'Compensation for Improvements by Tenants in South African Law' in Eltjo Schrage (ed) *Unjust Enrichment and the Law of Contract* (Kluwer 2001) 270.
[88] (1993) 3 SA 306 (T).

Alternatively, where the requirement laid down by a Celsus-Voet[89] approach are met in circumstances an action should lie. All that is required is that the judge be satisfied that beneficiary 'would have made such improvements himself'. Or 'that these kinds of expenses should fall within the normal pattern of expenditure'. An enrichment claim in such a case 'harmonises with, and does not subvert, the general idea of contractual liability as based on consent'.[90] Allowing the improver of another's property a claim should not be totally out of proportion to what would or could realistically have been contemplated between the parties themselves'.[91]

Applying this 'positive subsidiarity' to the facts in *Palabora Mining Co v Coetzer* Jooste however resorts to a highly discretionary approach apparently based on the Celsus-Voet approach above. He says:

'Certainly the mine being famously wealthy, they could afford it, and what is more, it probably would have been an immediately realisable benefit in the form of higher potential rental accruable. A swimming pool is certainly not a luxury item in *Palabora*, which is scorchingly hot and dry hell-hole with temperatures often in the higher thirties. There is therefore, in the circumstances of the case, nothing in terms of the subsidiary principle which would defeat the lessee's claim. It would have been different if, for instance the owner had been of modest means, or was not in his or her general course of affairs in the business of re-letting' the property, or if the home were situated in a climate hostile to recreational outdoor swimming'.[92]

What to make of this analysis?

Certainly most legal systems generally accept that where there is a subsisting contract between two parties, claims in unjustified enrichment are excluded. However, this observation should never be taken at first value. It is an oversimplification. There are instances in which enrichment claims are allowed in the presence of a valid contract. Such happens either because the contract does not speak to the status of the benefit in question,[93] or in other cases, the enrichment claims are denied, even though the parties'

[89] Celsus in D 6.1.38 'Suppose that the owner is a poor man who, if forced to pay such a sum [as compensation for improvements effected by a bona fide possessor], would have to give up his household gods and ancestral graves, it would be sufficient that you be allowed to remove what you can of the building materials…'; and Johannes Voet *Commentarius ad Pandectas* (Johannem Verbessel 1698-1704) 6.1.36 'Exceptions –'to the bona fide possessor recovering his expenses to the extent of the enhanced value are where such expenses are too heavy and the owner himself would not have incurred them. In that case he merely removes the results so far as he can…'.

[90] CM Jooste'Compensation for Improvements by Tenants in South African Law' in Eltjo Schrage (ed) *Unjust Enrichment and the Law of Contract* (2001) 270-271.

[91] Idem, 271. See however Article 1592 of the Italian Civil Code saying that the 'tenant is not entitled to restitution for improvements made without previous authorization of the lessor'. Obviously Jooste defends the applicability of the enrichment remedy in the circumstance based on what he calls 'tacit consent' or the Celsus-Voet approach (D.6.1.38 and Voet 6.1.36) or alternatively a justification analogous to the English 'subjective devaluation' or 'free-acceptance' principle.

[92] CM Jooste 'Compensation for Improvements by Tenants in South African Law' in Eltjo Schrage (ed) *Unjust Enrichment and the Law of Contract* (Kluwer 2001) 271.

[93] See for example the Canadian case *Hoffman v Sportsman Yachts Inc*, 89 DLR (4th) 600 (1992), (Ont.CA); The American cases *Toolrend Inc. v CMT Utensiles SRL* 198 F.3d 802 (11th Cir. 1999) (applying Florida law); *Elliott v Joyce* 889 P. 2d 43, 53 ALR 5th 791 (Colorado 1994) holding that a remedy of *quantum meruit* exists independently of any contract claim); for South Africa see *ABSA Bank v Stander* (1998) 1 (SA) 939 (CPD) and *Hubby's Investments (Pty) Ltd v Lifetime Properties (Pty) Ltd* (1998) 1 SA 295 at 298H-J where Cloete J held 'A right of retention cannot exist *in vacuo.* If there is a right of retention, there must be an action' and the explication that follows that assertion at 298J-299A-E.

contract no longer exists, because the now-discharged contract speaks to the status of the benefit in question.[94] Yet in other instances, what is required is simply that there is no inconsistency between the remedy in unjustified enrichment[95] and what would have been recovered had a breach of contract claim been pursued. In all these scenarios the defendant must not suffer injustice for allowing the unjustified enrichment remedy.[96]

In the instant *Palabora* case, no such injustice would arise though the facts do not square entirely with a proper contract, as a tenancy was terminated. The rule can still be applied similarly to a normal three party contractual scenario. There are further arguments supporting the contention that the contract-bar rule is not universal.

Therefore subsidiarity of enrichment claims to contractual claims cannot be assumed without qualification. On the issue of risk allocation, modern trend advocates that the contract-bar should only apply if the contract has allocated the risk of the event giving rise to the enrichment onto one of the parties. If there is a gap in the contractual allocation of them the subsistence of the contract is no bar to a claim in unjust enrichment.[97]

4 Conclusion

In conclusion, the analysis of the subsidiarity rule where there is interaction between contract and enrichment liability seems to yield the following result: there are usually two main groups of cases. One group is normally based on what I call 'defective consent'. The other group is based on policy considerations. Being this the case, it is safer to say that unjustified enrichment claims, based on defective consent, as opposed to those based on policy considerations alone, will not be allowed when there is a consensual distribution of risks and rewards. Put differently, the principle of subsidiarity must be operative at least in these last cases.

Seen from a corrective basis of enrichment liability, the exclusion of enrichment claims where there is a consensual distribution of risks and rewards, or what the parties have bargained for, the consensual distribution normatively operates to validate any transferred benefits and eliminates any prospect of normative gain or loss. This perspective leads to two consequences: The first is that a policy-based claim for unjustified enrichment can be made even in the presence of such a bargain because the normative flaw in the transaction is not inconsistent with the consensual bargain. The second consequence is that the perspective provides a positive reason for excluding unjustified enrichment claims (at least those that are not policy-based) whenever there is

[95] *American Jurisprudence* (2d 2001) Vol 66, p 624. It is also with similar reasoning that the South African judge in *ABSA Bank Ltd v De Klerk* (1999) 1 SA 861 (W) says: 'Mr Roos has requested judgment on the alternative claim. If my assessment of the situation is correct the reason is obvious: The choice of relief in fact lies with the plaintiff. Nothing in law compels me to exclude the alternative claim merely because the plaintiff made the *condictio indebiti* its main claim.

[97] Ralph Cunnington, 'Failure of Basis' [2004] *LMCLQ* 234, 251.

a bargain.[98] However, this conclusion is normally operative where there is a clear recognition of a general principle against unjustified enrichment.

The defence of change of position in unjustified enrichment law has nothing to do directly with the issue of enrichment liability as such. The defence properly analysed relates to the extent of the remedy which is awarded rather than to the negation of the plaintiff's cause of action. However, a careful analysis of the way in which liability is structured or constrained in a particular legal system shows that there is an impact on how the defendant may resist a plaintiff's claim. Because the doctrine of subsidiarity tends to deny plaintiffs' claims outright at the liability stage, the outcome is that the defendant may find himself with an undue windfall because the claim was prevented. That is of course 'good news' for the defendant. In such circumstances, the doctrine of subsidiarity unfairly places the risk on the plaintiff, should he be faced with unexpected difficulties in proving that the enrichment was *sine causa* and the other action being worthless pursuing.

However the notion of subsidiarity affects the defendant alike. Once the plaintiff has established a cause of action at the liability stage, generally then the onus shifts to the defendant in all enrichment claims. The defendant must now establish that it is inequitable for the defendant to make restitution because of the change of his position. Because the onus is now on the defendant, he has a chance to defend himself with all means. That being so, if a claim is not allowed at the liability stage, for being constrained by the doctrine of subsidiarity, the outcome is that either the defendant is freed totally from any liability, or if the claim is sanctioned in any other way, the plaintiff's measure of recovery may be flawed to the detriment of the defendant, because the other measures may not take into account any alteration in the defendant's circumstances. Therefore the concept of subsidiarity (specially an unqualified subsidiarity) leaves the assets of innocent and *bona fide* defendants vulnerable.

LINK BETWEEN KNOWLEDGE MANAGEMENT AND HUMAN RESOURCE MANAGEMENT

Nawaf Alshanbri[1], Vineet Tawani[2], Malik Khalfan[3], Farshid Rahmani[4] and Tayyab Maqsood[5]

[1-5] *School of Property, Construction, and Project Management, RMIT University, Melbourne, Australia*

ABSTRACT

This paper presents a brief literature review of both Knowledge Management (KM) and Human Resource Management (HRM) and demonstrates the link between them. We acknowledge the role of Intellectual Capital (IC) in bestowing competitive advantage to any firm and thus contributing towards its success. The paper also explores the role of KM and HRM both in sustaining IC particularly in the case of hiring for employees' replacement. Further, it also explains the relationship of HRM's main domains such as: selection, training, appraisal and rewards with KM in detail and their roles in the effective installation of KM system. Based on the extant literature, it reinforces (argues) that a new worker could be transformed to a knowledge-worker if appropriate transition processes were in place for knowledge retention and captured from leaving personnel. These knowledge-workers may be considered as talents that need to be nurtured under a suitable Human resource environment that supports the KM system. This paper confirms that the learning organizational structure provides conducive environment for knowledge-workers to realise his/her potentials. Finally, it concludes that if HRM is well linked to KM, then the replacement of employees may not be considered as a knowledge retention and capture problem for any firm.

Keywords: Knowledge Management, Human Resource Management, Intellectual Capital, Knowledge Worker, Knowledge Retention and Capture

INTRODUCTION

Unarguably, Knowledge is one of the key elements in sustaining the organization's success. A thorough knowledge of current systems at work leads to effective planning for future. Sustaining knowledge certainly needs a proper management and hence knowledge management is one of the important subjects in the organizational field. While, many organizations have developed the tools needed for managing and sharing knowledge within their employees by exploiting technology still a large number of them struggle to share knowledge with staffs. The literature about the issues of Knowledge management and the role of using technologies in managing knowledge is fairly rich and has been investigated at many levels. However, the literature of

Knowledge Management itself and its link with Human Resource Management is sparse (Afiouni, 2007; Haesli and Boxall, 2005; Har et al., 2010 and Maqsood, 2006). This paper contributes by investigating that link and attempts to clarify the importance of Human Resource Management themes for managing knowledge in order to achieve the sustainable success for organizations.

Knowledge Management and Intellectual Capital

Intellectual capital (IC) is an organizational asset, which provides competitive advantage. The proper management of IC has a significant impact in supporting and sustaining business life cycle. Nahapiet and Ghoshal (1998) define IC as "a valuable resource and a capability for action based in knowledge". Ulrich (1997) maintains that when effectively managed, IC may assist in achieving success and enhancing organizational survival and suggests that, Human resource (HR) departments should take the lead in dealing with IC. He also claims that this success might depend on attracting and developing individuals in order to retaining them. Further, Edvinsson and Malone (1998) classify IC into three categories: (a) Human capital: the organization's workers, (b) Structural capital: the organization's systems or work processes and (c) Customer capital: the relationship between the organization and its customers

Each category reflects key assets for any organization. Clearly, they focus on two main subjects: knowledge ("know what") and people ("know how"). Further, Davis (2009) suggests a "close link" between IC and the core process of knowledge (acquisition, codification, sharing, development and application).

Petersen and Poulfelt (2002) define KM as "the process of developing, sharing and applying knowledge within an organization to gain and sustain competitive advantages". Drucker (1993) supports the argument which KM is the only way to attain competitive advantage in this age. Further, Barney, (1991) suggests that gaining and sustaining the competitive advantage -"Knowledge" is related in the first place on human resources management, because human resources are considered the most critical aspect of organizational success. Ulrich (1997) opines the same about human resources. Even, Davenport and Völpel (2001) mention that managing knowledge is equivalent to managing people. When put together, evidently, there exists a relationship between knowledge and human resources. Dealing appropriately with just one of them and ignoring the other might negatively affect the successful implementation of a system that depends on knowledge and people. Storey and Quintas (2001, p 344) say "It is a paradox that, while so many authorities and commentators on knowledge management (KM) have come to the conclusion that KM ultimately depends upon people, it is precisely the people (or HR) aspect that has been the most neglected in studies in this field". Hislop (2003) explains that KM and HRM integration is still not complete and effective. Chen and Huang (2008) suggest that both human resource management (HRM) and KM strategies need to be integrated to derive benefits from the IC and thus increase the organization's performance and achieve success. While the KM literature acknowledges the importance of people management themes, still it has not reached the next step of investigating and theorizing them in detail. Clearly, though HRM and KM are established management concepts, the significance of HRM in KM is only partly realized. Ruggles (1998) includes research conducted on a 431 U.S. and European organizations, and concludes that most organizations acknowledge that knowledge is highly people-based yet these organizations' efforts in KM are towards technology implementation. Though

organizations can facilitate creation, sharing, and knowledge transfer by having the latest and newest technologies; yet their effectiveness in managing KM is not absolute (Hislop, 2003). May be the integration of HRM with knowledge management has not been completely achieved primarily due to a lack of studies relating KM with IT.

In conclusion, in order to achieve success and optimum benefits from its resources, it is vital for the organizations to pay more attention to their internal capabilities, specifically people and their knowledge. The aim of this analysis is to show how strong links between KM and HRM may affect the ways organizations hold knowledge and assist the staff replacement process. To our knowledge, there exists no prior research related to staff replacement on a nationwide scale. This research attempts to fill this gap and to help understanding the links between KM and HRM.

Thus far we have established that Human Resources Management has strong relations with Knowledge Management and that gaining the competitive advantage of "knowledge" is all about managing, developing and retaining people. It also implies, that losing people is equivalent to losing knowledge.

Role of HRM strategies in effective KM:

Influencing human resources towards knowledge sharing is a key to KM. Soliman and Spooner (2000) emphasized that employees' involvement, commitment, and trust will foster the application of KM. This involvement can also be controlled and managed under Human Resource Management (HRM). Shih and Chiang (2005) also argue that to achieve the main goal of KM, which is effective knowledge transfer, organizations' HRM strategies and practices should play the central role in knowledge management. Hence, the role of HRM practices in facilitating knowledge absorption, creation, sharing, and transfer is critical. HRM strategies need to be aligned with the corporate and KM strategies to derive consistent competitive advantage.

Shih and Chiang (2005) argue that the adoption of proper HRM strategy and practices facilitates the successful implementation of a KM strategy. They also suggest a model. For instance, if corporation has a cost-leadership strategy, the KM strategy would be a codification strategy and the HRM strategy would be buy-bureaucratic HRM strategy with close supervision and high control to minimize cost of errors, result-oriented performance, limited training, etc.

According to Storey (1989), the traditional HRM domains revolve around selection, training, appraisal, rewards, and performance management systems. These HRM domains take a "different colour" when they contribute to organizational knowledge assets (Narasimha, 2000). According to Storey and Quintas (2001), HR professionals confront five key challenges in dealing with knowledge: developing and sustaining the knowledge culture in the organization, accessing employees' tacit knowledge, securing trust and commitment between employees, handling non-traditional employees such as knowledge workers, and "handling the organizational vulnerabilities arising out of a heavy dependence on key knowledge workers" (Afiouni, 2007).

All the discussion thus far highlights issues related to employees more than knowledge system itself and suggests that HRM strategies need to be equipped with knowledge processes in order to achieve effective KM. The next few sections evaluate HRM domains and their effects on KM.

Selection process and KM:
Organizations adopt highly advanced and complex methods of selecting and recruiting employees to attract the best talent in the market. To create a knowledge repository and increase the benefit of sharing knowledge between employees, selection of individuals with competent skills and the right attitude is essential. Highly innovative selection processes have been introduced that are technologically sound and efficient (Scarbrough, 2003). Selection processes are customized to the job descriptions and corresponding skills and competencies that ensure the right candidates are hired for the job. However, such customized selection processes can conceal certain employee behaviours as mentioned by (Narasimha, 2000).

Training and Knowledge Management:
Training activities are regarded as core knowledge sharing processes. The most important practices adopted by HRM are KM processes. Training is a process that directly connects HR personnel with other employees in order to source knowledge transfer, which stands at the core of any KM process. Training also plays an important role in the development of the three dimensions of organizational knowledge: breadth/depth of knowledge, competence, and exploratory/exploitative knowledge (Narasimha, 2000). Training provides an opportunity to improve employee performance through work-related knowledge and skill-development (Swanson, 1999). Tacit and explicit knowledge related to skill-specific work can be transferred through systematic and frequent training (Robertson and Hammersley, 2000). Har et al., (2010) hypothesized that training leads to higher knowledge transfer. Frequent training that supplements organizational knowledge can be accomplished by creating a learning culture. In conclusion, training is a practice that improves competitiveness, enhances technical and social learning, results in knowledge acquisition outside one's main domain, and improves overall business performance.

Performance management and KM:
Performance management processes can make an important contribution to knowledge management by setting behavioural expectations related to knowledge-sharing, ensuring that actual behaviours are reviewed, and where appropriate, establishing financial or non-financial rewards (Armstrong, 2006). Performance appraisals aim to provide role and goal clarity to individuals, and are key process by which employees' performance and improvement is assessed. Soliman and Spooner (2000) posited that HR can drive KM by evaluating employee performance, providing feedback for leadership, enhancing the decision making capabilities of individuals, creating interpersonal relationships, minimizing high turnover and absenteeism, and clarifying roles and goals. Performance appraisals should be designed to evaluate the degree of usage of competencies, which can be taken as indication for further training and development (Narasimha, 2000).

Rewards and KM:
The means to improve knowledge sharing have to be motivational, and rewards and recognition must improve employee motivation and commitment. Har, et al. (2010) suggested that learning behaviours should be rewarded when performance is achieved in order to avoid negative effects on employees' performance and failure to achieve desired outcomes. Furthermore, Bartol and Srivastava (2002) emphasized that reward structures are necessary to motivate people to communicate and to share their knowledge. Employee commitment and willingness to share are critical to knowledge sharing processes. Employees can be motivated to share knowledge through rewards

and recognition (Storey and Quintas, 2001). Moreover, motivation by rewards and recognitions will assist in encouraging innovation in different aspects such as products, services or communication style between staff. Knowledge sharing that is backed by a reward system is an excellent tool to install KM in an organizational culture through group performance, knowledge sharing, and innovative thinking (Yahya and Goh, 2002).

Knowledge worker and Talent Management in learning organization:

Talent management is one of the most important concepts in contemporary management that is pressured by globalization issues, immense competition in labour market, vast advancements in information and technology and enormous struggle to compete in businesses. According to Serrat (2010; p.3), talent management can be consider as an "additional processes and opportunities" that an organization can make available strategically to a group of people who are "deemed to have talent".

Serrat (2010), asserts that the ignorance of talents from human resource management in any organization can be consider as "untapped quality to be accessed in the future" or unused efforts that the organization can benefit from in the future which will have an effects on both; talented staff and the organization.

These statements show the significance of talent management. Knowledge worker can be considered as a talent for the knowledge that s/he obtains. Drucker (1999) refers to knowledge workers as capital and not labour. Employees with specific skills and talents can use their ideas and expertise during turbulent times, which can add great value to organizations during such challenging situations (Lawler, 2008). Talent management of knowledge workers is highly essential as it creates value for their knowledge; it creates systems and procedures that track and manage the talented personnel. Bano et al., (2010; p.7) assert, 'The organization which is dealing with the management of talent strategically and purposefully explains that how they attract, source, select, develop them by trainings and ultimately retain them by promoting and rotating them throughout the organization.' Knowledge workers' turnover is a major challenge to firms because when the knowledge workers leave, they take along their tacit knowledge. Even if firms develop highly sophisticated codification processes to tap employee knowledge, these processes cannot capture the employees' willingness, attitude, and passion for knowledge. Hence, the focus of HR towards talent management of knowledgeable workers should constitute appropriate selection, rewards and training beside KM processes.

The knowledge workers are a part of the human capital that is developed through continuous learning and innovation. A learning atmosphere that provides flexibility and a holistic learning opportunity for knowledge creation and sharing is most favourable for knowledge workers (Storey & Quintas, 2001). A learning organization instills learning behaviour in their culture; they have a supportive and encouraging leadership; strong information and technology base; strategically aligned rewards and performance management system; and constantly strive for employee retention (Nelson & McCann, 2010). Organizational culture influences the behaviours required for KM in four ways. Firstly, it educates people about KM and highlights the critical knowledgeable aspects. Secondly, it establishes a relationship between individual and organizational knowledge. Thirdly, it creates framework for network processes for fostering knowledge sharing and usage. Lastly, it shapes processes for creation, sharing, and usage of new knowledge.

As discussed above, there is a strong relationship between KM and HRM. These issues have not been thoroughly explored, nor has the relationship or its effects on retaining knowledge been documented. Furthermore, in spite of the immense work related to KM strategies for knowledge retention via IT systems and tools, knowledge retention along and employee recruitment or replacement remain one of the core strategies that have not yet been developed (Wong, 2008).

Forcing a company to replace its employees can have significant effects on the company's success. Employee turnover can potentially cause knowledge loss. This issue is going to happen in one of the Middle East countries. In Saudi Arabia, the new localization program "NITAQAT" that launched by the Ministry of Labour last June 2011, which aim to replace foreign workers in the country with locals" will lead to the export of a huge amount of knowledge outside the country. Replacing foreign workers with domestic labour will take place on a nationwide scale, and the foreign workers' knowledge, which could be considered as the most valued asset in this stage, will be lost. This loss of institutional knowledge will affect the country on many levels, including economically and socially.

In order to transfer foreign workers' knowledge successfully to the local labour market, the country should act soon to retain the needed knowledge and maintain the competitive advantage of IC. This can be accomplished by using the benefits of good KM strategies for firms/organizations with the right strategies and practices of HRM and applying them on a larger scale.

CONCLUSION

The effectiveness of HRM in sustaining KM, and the role of both KM and HRM in supporting employee replacement processes, is the main goal of this paper and it is a part of a PhD study that will study the Saudi Arabia's new localization program "NITAQAT". This research will further examine these strategies in order to understand the impact of KM strategies and HRM strategies on organizational effectiveness. In order to avoid losing knowledge while maintaining the competitive advantage of IC, the study will investigate KM-HRM links in order to assist the employee replacement process. Moreover, the study aims to test the current status of the Saudi Arabian organizations and its ability to adopt KM and HRM links.

REUSE OF DOMAIN KNOWLEDGE TO INCREASE ADOPTION OF OFF-SITE MANUFACTURING FOR CONSTRUCTION IN AUSTRALIA

Sittimont Kanjanabootra[1], Moe Wynn[2], Chun Ouyang[3], Russell Kenley[4] and Toby Harfield[5]

ABSTRACT

Many construction industry decision-makers believe there is a lack of off-site manufacture (OSM) adoption in Australia. Identification of construction business process to assist decision-makers to increase OSM adoption is a proposed solution. The premise that domain knowledge can be re-used to provide an intervention point in the construction process led a team of researchers to develop base-line process models for a generic construction project. Sixteen domain experts in the Australian construction industry were asked to review the base-line process model related to Arranging the Project Team by answering the question "Where in the process illustrated by this base-line model has OSM implications?". Through an iterative and generative process a number of off-site manufacture intervention points were identified and integrated into the base-line process models. The re-use of industry expert domain knowledge provided suggestions for improvement to current practice. It is expected that implementation of the new processes will lead to systemic industry change and thus increases adoption of OSM.

Key words: Australia, construction knowledge reuse, OSM adoption.

INTRODUCTION

Off-site manufacturing (OSM), off-site assembly, off-site fabrication and prefabrication are modern methods of construction. For simplicity in this paper OSM is used to indicate a number of different process types that take place distant from the construction site. There are a numbers of factors that foster the adoption of OSM according to the extensive literature (Nadim and Goulding 2011; Blismas and Wakefield 2009; Goodier and Gibb 2007). OSM offers better waste control through coordination and use of a controlled environment. In times of skills shortages, OSM

[1] skanjanabootra@swin.edu.au
[2] m.wynn@qut.edu.au
[3] c.ouyang@qut.edu.au
[4] rkenley@swin.edu.au
[5] tharfield@swin.edu.au

can solve the problems of limited on-site workforce availability. In addition, repetitive standardised processes, such as constructing door frames, can be controlled for quality more effectively using a single manufacturing facility. However, OSM adoption is still limited outside of the residential housing sector (Nadim and Goulding 2011; Blismas and Wakefield 2009). Rodriguez-Melo and Mansouri (2011) suggesting that stakeholders, including clients, architects, engineers, project managers, builders, contractors and suppliers are unable to make decisions to utilise OSM due to the lack of understanding OSM processes (Goulding et al. 2012; Kenley et al. 2012).

Smith (2010) however, suggests that some construction stakeholders do have specific domain knowledge concerning OSM processes, but do not effectively share this knowledge with other project stakeholders. Sharing domain knowledge can facilitate problem-solving and decision-making that enables cost trade-offs thus improving manufacturability and increased product quality (Lawson, et al. 2009). Domain knowledge is a defined concept in a number of disciplines such as education, psychology, engineering, and information technology (Vitharana et al. 2012). The concept is widely used with multiple meanings: cognition, language acquisition, professional practices, institutional processes and information systems.

The common thread for application of the concept of domain knowledge is that individuals, groups, organisations and temporary organisations such as construction projects can create, store, disseminate or reuse specific process knowledge. In the construction industry most of the expert knowledge is related to occupational domain knowledge such as engineering or project management. Thus one mechanism of providing support for increasing adoption of OSM could be linking specific domain knowledge about construction off-site manufacture with current construction projects processes. However, many studies have shown that individuals, teams and organisations become ‘experts’ about specific tasks and processes, but often with limited ability or desire to reuse that knowledge for change (Kanjanabootra 2011).

Self-interest and competitive advantage are often cited for lack of knowledge sharing, but studies also indicated that knowledge sharing has a positive net effect (Harfield 1999). This is especially true in relation to innovation or changes to traditional industry practices (Kanjanabootra and Corbitt 2010; Heywood and Kenley 2008). The difficulty appears to be that individual domain knowledge cannot be reused and applied outside of the knowledge process framework of an individual unless specific mechanisms are in place to facilitate that domain knowledge reuse.

For example, Heywood and Kenley (2008) introduced a competitive advantage framework for corporate real estate. Their study reports that managers knew about CRE functional practices such as financial management and resources allocation, but they did not know how to reuse this knowledge for competitive advantage practices. In one part of the framework the authors provide a competitive advantage framework (fit to purpose) for location selection. This new dimension to the decision-making processes assists managers in developing strategy, which has now become a core CRE activity. In much the same way, this study aims to provide OSM adoption

frameworks for construction industry stakeholders in Australia to re-use their domain knowledge.

RESEARCH DESIGN

The aim of the study is to develop a mechanism to facilitate domain knowledge re-use through domain knowledge sharing concerning OSM adoption for construction projects. Specifically the research focuses on development of construction project process models to provide the framework for the reuse of construction stakeholder domain knowledge (Demian and Fruchter 2006.

Business Process Management

Business process management (BPM) systematically documents, manages, automates and optimises business processes (Weske, 2007). This is achieved by promoting a process-centric view of an organisation through end-to-end management of business processes. Business processes are activities in a sequence that have conscious or un-conscious decision-points linked to them. For example, when we go into a bank to deposit money the teller takes our money and provides us with evidence of the transaction. The money goes into a specific drawer, in a set order, and a copy of the transaction is entered into a computer database. These sequential activities are called 'depositing'. These activities involve human interactions and decision-points throughout the process of depositing. These activities are also linked to other business processes, which make up the complexity of process we know as 'banking'. From a process perspective, all organisations, industries and projects are sets of inter-linking processes providing frameworks within which business operates.

The purpose of business process management is to identifying processes in order to provide the mechanism for change. The BPM lifecycle typically has a number of distinct phases: design, implementation, enactment and diagnosis with the intention of creating an IT system change mechanism (Dumas et. al 2005). Each of process identification lifecycle phases are generative and iterative (Holliday 2007). For example, during the design phase, the process requirements are gathered from stakeholders (multiple viewpoints) resulting in an initial set of base-line process models. These models are used for further communication with stakeholders assisting them in sharing their domain knowledge for all phases of BPM.

A business process model can be depicted using a number of different process modelling languages, each with their own advantages and disadvantages (White and Miers 2008). In this study we use Business Process Modelling Notation (BPMN). BPMN provides a visual representation of the order of activities taking place within business processes together with the types of people who normally do these activities. Another important category is the information required for these activities, especially because the expected outcome of BPM is an IT-based change process

Construction Process Models with OSM Intervention Points

Stage One of this study developed a simplistic generic construction project process model encapsulating the research scope. This draft process model was informed by a review of construction industry professional knowledge-based literatures. The draft model provided a high-level overview of a generic construction project enabling researchers to identify key activities, resources and information linked to defined project phases. A second level of complexity was captured in draft models of six

phases. These were refined using the domain knowledge of the research team (Mechanical Engineering, Project Management, Quantity Surveying, and Building). For more information concerning the construction projects phases see Kenley et al. (2012). For clarity, only a section of one phase base-line model is shown in figure 1 as an example of process model development for this research.

Figure 1: Section of Base-Line Process Model, Arrange Team (Multiple Viewpoints)

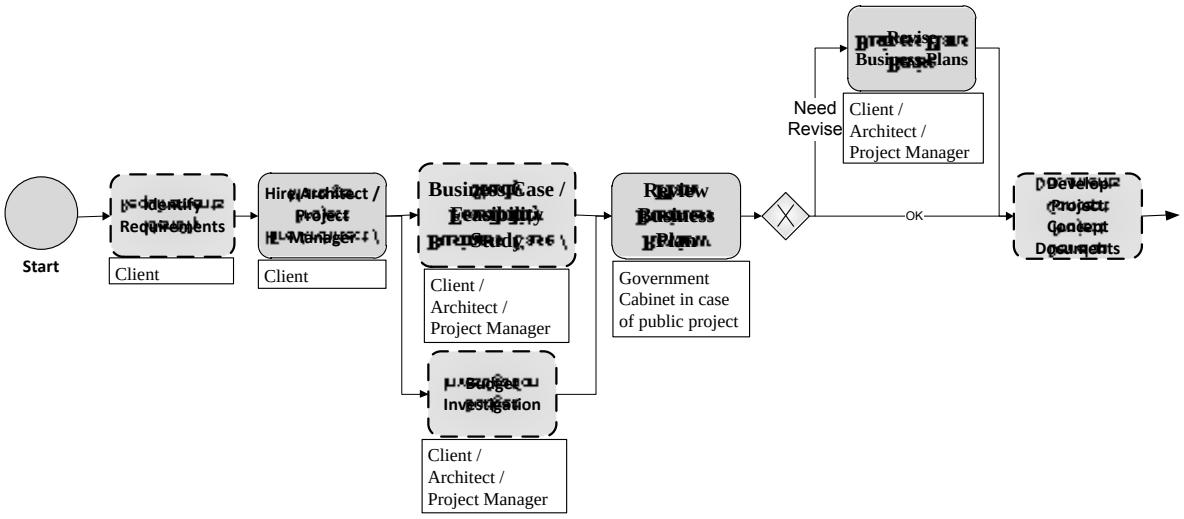

Figure 1 is an example a BPMN generated process model. It provides a picture of activities (in the grey box) relating to specific stakeholders such as the client or architect (in the white box) involved in arranging a construction project team. The addition of government as a stakeholder is because in Australia most the infrastructure projects are government initiated. This model illustrates high-level processes related to different categories of activities: resources, such as Budget Investigation or information, such as Review Business Plan. The sequencing is indicated by the arrows. The possible OSM intervention points identified in the literature are indicated with the dashed-line grey activity box.

Complex models of all phases of a generic construction project, developed as base-line process models, became the framework used to obtain construction industry stakeholder domain knowledge for reuse (Kanjanabootra 2011). This report describes domain knowledge reuse collection and application in the base-line process model section of Arrange Team phase shown in figure 1.

DOMAIN KNOWLEDGE REUSE

The definition domain knowledge reuse is when personal knowledge of how to do a task (a process) is used to do a similar task in another context (Kanjanabootra 2011). *Stage Two* of the research attempted to capture the domain knowledge for re-use within the context of OSM adoption interventions. Interviews with construction industry professionals resulted in model modification related to usability (based on expert domain knowledge). Modifications requested during stakeholder interviews were incorporated in the base-line model used in the next interview, forming eight generative iterations (Vitharana 2012). In this way changes were also verified as

usable for multiple domain knowledge areas. This open-ended qualitative approach (Holliday 2007), involved an opportunistic sample of 16 experts (see table 1).

Table 1: Domain Experts and their Expertise for Knowledge Re-use

Domain Experts	Number =16	Type of Organisation
Architect	2	Australian-based International Architectural Organisation
CEO	1	Australian-based Consultant for BIM and Precision Instruments
Government Client	4	Government Buildings and Works (Finance)
Project Manager	5	Australian-based International Infrastructure Contractors
Site Manager	3	Australian-based International Infrastructure Contractors
Service Supervisor	1	Australian-based International Asset Management

The base-line model in figure 1 was firstly used to verify possible OSM intervention points (the boxes with the dashed borders). The first column of Table 2 indicates the experts' answers to the question "Where in the process illustrated by this base-line model has OSM implications?" The second column shows suggested process modification to the base-line model activities (see Figure 2) related to re-use of personal knowledge by the domain experts interviewed.

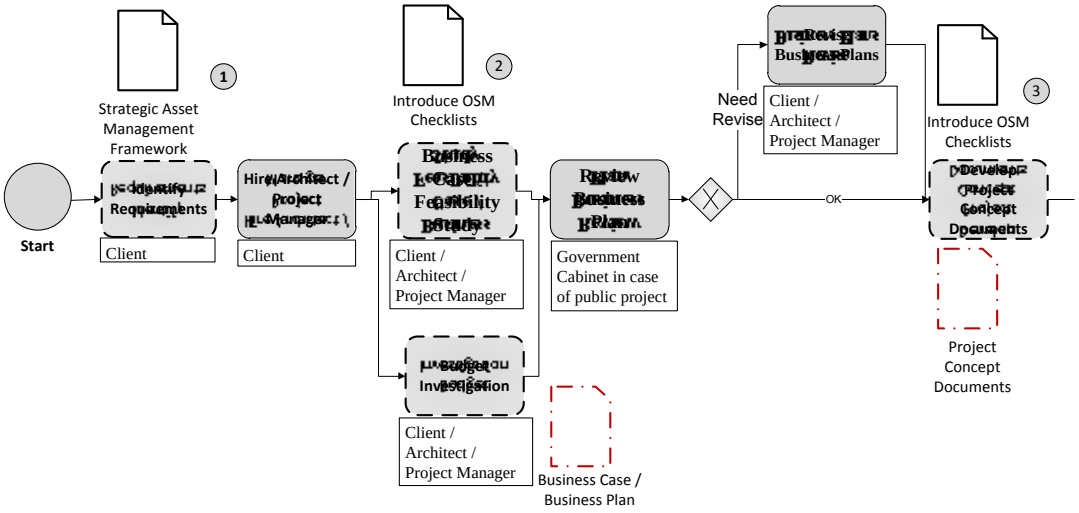
Table 2: Changing the Process by Adding an OSM Adoption Intervention

Domain Knowledge Re-use Interview Data	OSM Intervention (number in Figure 2)
"It is often the OSM concept has not been initiated during the "Identify Requirements" and the project has been carried away into the design phase and the project is trapped in the non-OSM concept which is difficult to change."	**1** Additional Process: Organisational Strategic Asset Management Framework review has been added to the task of developing the project requirements to ensure that the option of OSM is included as per the SAMF.
"There is a lack of OSM option analysis guidelines to help governments make decisions during the 'Business Case/ Feasibility Study', as a result the project team cannot see overall benefits of adopting OSM."	**2** Additional Process: OSM checklists to assist project teams evaluate OSM adoption in order to make a business case.
"Ideally, it would be useful if we have some input or comments regarding to production process and transportation aspects from suppliers/contractors during 'Develop Concept Documents'.	**3** Additional Process: OSM checklist to assist with project logistics for OSM options along the supply chain.

Based on the outcomes of the interviews, base-line construction processes modelled in BPMN for *Stage One* of the research were modified. Figure 2 illustrates the first section of the modified process model. The first activity Identify Requirements has been verified as an activity as OSM intervention point (depicted using dash-line) which is carried out by a client. Number 1 (in the grey circle) indicates the addition activity suggested through the reuse of domain knowledge: the sheet of paper is the BPMN notation for information linked to an activity, in this case the Strategic Asset Management Framework. Number 2 (in the grey circle) the 'Business Case/Feasibility Study' and 'Budget Investigation' activities undertaken by various people were also verified as opportunities for OSM adoption. Domain knowledge

reuse in the form of decision-making checklists have been added to the process model. Number 3 (in the grey circle) is linked to additional information needed, in the form of a checklist, at the 'Develop Project Concept Documents' activity.

Figure 2: Example of Domain Knowledge Reuse Modification of Base-Line Model



Industry expert understanding the purpose of a construction project process of Arrange Team has provided innovations to that process. Figure 2 shows the modified process which is facilitated the re-use of their personal domain knowledge at each OSM intervention point. As with all innovation, the new process is expected to be a more effective way of doing the same activity (Kanjanabootra 2011). In this instance the activity of arranging the projects team will have more information about OSM adoption at an earlier stage in the construction project process.

CONCLUSIONS AND FUTURE RESEARCH

This report describes research into how to provide OSM adoption frameworks through business process base-line models. This paper has been able to provide only three examples of OSM intervention points being created through domain knowledge re-use in the base-line model. However, it is clear that even these small process interventions have the possibility of a large effect. The reuse of individual domain knowledge for innovation is evident because the industry experts interviewed for this research requested specific modifications to the identified construction project process models. The effect of sharing this re-used domain knowledge to support OSM adoption means that other industry stakeholders will now be able to be able to consider OSM adoption earlier in the construction process. The modified processes are expected to increase stakeholder confidence in perceiving opportunities for productivity gains through OSM adoption.

Stage Three of this research will be the creation of an IT-based prototype of the processes that have been integrated in the Baseline Models throughout *Stage One* and *Stage Two*. The pilot application using process/workflow technology will be able to provide automated support for selected tasks. Thus, a demonstration of how an IT-based tool that can provide automated support for adoption of OSM. It is expected the tool will facilitate knowledge sharing among industry stakeholders. For example

the tool could be used together with documents including embedded OSM checklists for specific projects to expedite changing project processes. The tool will also have the ability to integrate with other technologies within the construction industry such as BIM systems thus becoming a champion for change: increasing OSM adoption.

ACKNOWLEDGEMENT

The authors acknowledge the funding and support provided by Australia's Sustainable Built Environment National Research Centre (SBEnrc) and its partners. Core Members include Queensland Government, Government of Western Australia, John Holland, Parsons Brinckerhoff, Queensland University of Technology, Swinburne University of Technology, and Curtin University. Health and Safety - Teaching the Law and Educating for Prevention

Carrie de Silva[1]

[1]Harper Adams University College,
Newport, Shropshire, TF10 8NB,
United Kingdom

Email : *cdesilva@harper-adams.ac.uk*

Abstract:
The teaching of law to non-lawyers can involve an unreceptive audience, particularly when the subject is health and safety. The author works with prospective rural practice chartered surveyors who are likely to be professionally involved with the two highest risk working environments in the UK : construction[1] and agriculture.[2] Unlike construction, the agricultural industry has failed to reduce annual fatalities in the past quarter of a century and continues to account for around 20% of workplace deaths, whilst employing under 2% of the workforce.[3] This paper explores the use of court cases, as an introduction to studies, to pique student interest, enhance legal skills and, importantly, to attempt to influence life-long behaviour for those with future responsibilities in these areas. Students are also exposed to the field work of the Health and Safety Executive. The paper sets out some of the issues and experiences of teaching health and safety law to non-law students, outlines the cases used (for the 2011/12 cohort) and reviews the responses to preliminary research ascertaining student attitudes and understanding of the area before and after teaching.

Keywords:
health and safety, law teaching, surveyors.

1 Introduction - home institution, courses and study

This paper is based on the author's teaching experience on law modules to students of the RICS[4] accredited rural land / estate management undergraduate and post-graduate 0rural Shropshire, between Birmingham and the Welsh border and was, until 1995, known as an Agricultural College. It was founded in 1901 on the legacy left by Thomas Harper Adams in 1892 (Williams, 2000). The College has a working mixed[5] farm of nearly 1,000 acres together with 175 acres of woodland. The

[5] Dairy, beef, sheep, pigs, poultry and arable.

agricultural roots of the college are apparent from the notice outside rooms urging students to remove their wellies before entering!

It is worthy of note, that the degree course in question has a vocational focus and the vast majority of students (normally well over 90%) go into course relevant graduate jobs each year, i.e. as trainee chartered surveyors in rural practice, with the most of the remaining students going into agricultural consultancy, non-rural surveying, farming and just one or two a year going into completely unrelated jobs.

The objective of this study is to reflect on the issues raised by teaching law to non-law students, particularly in the key area of health and safety law, using evidence of student attitudes, understanding and achievement to inform the development of effective pedagogic materials and techniques.

2 The imperative of understanding health and safety law and practice

Health and safety is a subject which should be covered at various points in a land based curriculum, most certainly not just becoming a 'tick box' exercise, a symptom of poor practice in the sphere of health and safety which is all too prevalent[6]. In the undergraduate course it is currently introduced in the first year as one lecture in an introductory law module, supported by a tutorial session and on-line quiz, in the second year in a number of pre-placement briefings and exercises (all students do a mandatory sandwich year) and in the final year in a professional practice module. It is also addressed in a range of practical situations in modules involving, for example, construction, agricultural machinery, livestock and site visits to farms, woodlands and estates.

As an adjunct to the in-house delivery, the Health and Safety Executive, Agriculture Sector, work closely with the institution and give an annual talk and video showing pictures of shocking injuries and even fatalities and some harrowing footage of close relatives of victims discussing the personal and practical cost of serious injury and death, often in the context of a family business. These materials are not replicable and are an invaluable aid to embedding the message of safe working practices and management.

The subject is particularly relevant in the sector involved as in agriculture and related industries (such as forestry) there were 42 fatal injuries in 2010/11 with a corresponding rate of 8.0 deaths per 100 000 workers, compared to an overall rate across all workers of 0.6 per 100,000. In construction there were 50 fatal injuries, with a rate of 2.4 deaths per 100 000 workers (Health and Safety Executive, 2011). Comparing the figures of 1987/88 where the rate of deaths per 100,000 was 10.2 in agriculture and 10.7 in construction, although there is improvement, clearly in over 20 years agriculture and the land based sector has not made the strides of other hazardous occupations. This picture is replicated in other western countries.[7]

An understanding of the need for and content of health and safety teaching has evolved with reference to various sources. Several members of staff are practicing rural chartered surveyors, examiners for the RICS and other relevant bodies such as the CAAV (Central Association of Agricultural Valuers) and the ICF (Institute of Chartered Foresters) and are thus well placed to know what students require in their future working lives, as is vital on vocational courses. Regular liaison, in course development, with practitioners highlights health and safety as being of major importance and a level of competence is mandatory in qualifying as a chartered surveyor (RICS, July 2006). The number of workplace fatalities and serious injuries in the past year in rural practice,[8] with (from industry discussion) an increasing concern in livestock markets, has highlighted the need for an understanding of the legal framework and compliance, for legal and financial reasons and, of course, to protect the health, safety, welfare and possibly, life, of employees and others. As well as the importance of understanding the issues as individual workers, the students will often have responsibility for other staff, premises and contractors at an early stage in their careers.

In developing effective teaching methods and materials, the long term goal is to try impact behaviour (Gielen and Sleet, 2003) in the land based sector. Whether the most effective means of imparting the health and safety message is through ever more straightening legislation and sentencing (Zimring and Hawkins, 1971; Hawkins, 2002), through general industry publicity such as the press (Ozegovic and Voaklander, 2011), through behaviour-based management (Stranks, 2009) or through formal, classroom education (Germeni *et al.*, 2009 and 2010) such as is under consideration in this paper, is a matter for further research.

This, then, directs thinking very clearly to the *purpose* of teaching non-law students - not to get students to 'think like a lawyer' (Mertz, 2007), but rather to impart practical information directly relevant to their working lives (Morris, 2010). The health and safety curriculum clearly illustrates the interaction of primary law - the legislative framework and a body of cases - with reference of how to comply with that law in terms of practical workplace behaviour, from carrying out risk assessments to the practical matters such as lone workers leaving contact details, location and expected time of return, not carrying out certain animal handling operations unaided, leaving tractors in a safe position, and so forth - good practice as well as an understanding of legal liability.

This emphasis on skills (Cox, 1992) and context (Saunders and Clarke, 1997) rather than purely 'knowledge' (Harris, 1992) is, of course, a feature of the law, as well as non-law, curriculum, discussed for decades and encouraged nearly a quarter of a century ago by the Marre Committee Report (1988). It enables a greater interaction between law and non-law pedagogic literature and lecturers with an inter-disciplinary relevance that was, perhaps, not always the case. The need for context is, then, embedded in course objectives (Woodcock, 1989) with the imperative of carefully considering how the law will impact the working life envisaged by most of the students (Endeshaw, 2002).

for Health and Safety in Agriculture - http://www.cchsa-ccssma.usask.ca/aboutus/index.php ; for Australia see Australian Centre for Agricultural Health and Safety - http://www.aghealth.org.au/ (viewed 21st May 2012).

[8] The unconfirmed figures from the Agriculture Sector of the Health and Safety Executive for 2011/12 are 50 agricultural (and related) industry deaths.

Having established that health and safety law needs to be taught for substantive content, to comply with professional and practical needs and, of course, to develop transferable skills beyond the acquisition of core knowledge - what problems have been encountered in attempting to cover this area with non-law students?

3 Teaching Law to Non-Lawyers

When teaching law, that there is a difference in learning styles and receptiveness between law students and non-law students has long been acknowledged by researchers (Twining, 1967 and Richard, *et al.* 2009). The teaching of law to non-lawyers can involve an unreceptive audience, particularly when the subject is health and safety, based on student perceptions of relevance (Dobson and Marsh, 2008), accessibility and pedagogic issues surrounding delivery.

As prospective rural practice chartered surveyors the students can find 'black letter' law dry and demanding (see Hutchinson, 2005, for a useful comparative discussion of the legal content of construction and surveying courses across seven institutions). This paper explores the use of court cases to engage student interest, enhance legal skills and underpin wider legal studies and, importantly, to influence behaviour for those with future responsibilities in these areas. The paper also includes responses to preliminary research ascertaining student understanding of the area before and after teaching.

3.1 Academic Range

The course in question involves a wide academic range of students due to the specific professional focus of the course and the limited number of institutions offering a rural practice specialism.[9] For most UK university courses it would be unusual to have a course with an entry requirement of 280 UCAS points (in 2011/12) to have applicants with three, or even four A grade A2s. Students also come in with 'A level equivalent' qualifications such as BTEC National Diplomas in vocational subjects such as Agriculture or Countryside Management. This academic diversity makes the careful consideration of teaching methods particularly important (Davis, 2003), to help ensure the inclusion of those coming in with lower previous academic achievements, whilst maintaining the interest and fully challenging and developing the most able.

3.2 Relevance?

Pleasingly, (mercifully!) some students clearly understand the relevance of health and safety law, particularly as they will be undertaking a working sandwich year (all Harper Adams undergraduate degree programmes include a mandatory placement year, which for most students includes APC[10] registration) which ensures that formal employment is a key feature of the course culture from the outset. Many students also have extensive agricultural work experience or experience in other potentially hazardous environments such as livestock markets or in property businesses.

[9] The Universities of Cambridge, Reading and Aberdeen offer closely related courses but only the Royal Agricultural College at Cirencester has a direct equivalent.

[10] Assessment of Professional Competence - the work based element required for RICS qualification as a chartered surveyor.

However, although, as lawyers we might live and breathe Lord Wright's : 'Law in its own way covers the whole range of human activity …' (Gower, 1950) others, who have not really considered what their chosen profession actually involves, do not always arrive at university ready to embrace legal studies (Allen, 2007).

Effective teaching requires that students understand the relevance of their studies and that their engagement is maintained and the effective lecturer will constantly evaluate, both formally and informally, whether this is occurring and adjust delivery and materials accordingly (Ramsden, 1992 and Corbin, 2002). In developing an understanding of relevance, and best engendering learning, utilising students' existing knowledge of practical situations and relating the operative law to that setting through case studies has been found to be effective (Oppenheimer, 1999).

3.3 Demanding?

As the teaching of health and safety matters is underpinned by an overview of the key primary and secondary legislation (this being, of course, a densely regulated subject) the nature of the material and the unfamiliar terminology can make the subject forbidding for some who can be, as expressed by Allen in her considerable work on teaching law to business students, 'alienated' by the discipline (Allen, 2007). This is not the place to explore perceived standards of British secondary education - the students arrive at the start of the first year as a product of their preceding education (Datta and McDonald-Ross, 2002), but it is clear that the written language of law can be unfamiliar (Vick, 2004), inaccessible (Christudason, 2004) and generally overwhelming (Allen, 2007) to some, even those whose entry qualifications mark them out as more 'able'.

In a vocational, non-law course, students perceived demands of legal studies are often exacerbated by comparison with other modules, such as Forestry. There has been a consensus, following discussions in Course and Examination Boards, that all modules on a course need not be of precisely equal demands if, indeed, such an exact science were possible.

So the challenge is to present materials which are demanding enough to be accurate, to stretch ability and to develop higher level cognitive processes (Bloom, 1956), whilst being accessible (McGeveran, 2007).

3.4 The *Law* Lecturer

A final and, obviously, crucial feature that can impact the success or otherwise in the teaching of law to non-lawyers (or any teaching, for that matter) is, of course, the lecturer. Those who read law may be immersed in 'black letter' content and the traditional domination of the study of primary sources (Soetendorp and Byles, 2000) probably through the medium of lectures, tutorials with a heavy pre-reading load and assessment through essays.

That a concentration on legislation and precedent, with little reference to context and the wider world, is limiting has been recognised well over a century (Holmes, 1897). It is, then, most certainly apparent that the 'law school' approach is inappropriate to courses where, in particular, (a) the students will not / cannot / are unlikely to engage in a high volume of reading, (b) where a wide range of topics have to be covered in

limited detail, and (c) where the nature of the subject has, as with health and safety, a very practical aspect.[11]

This concern of a black letter approach for non-law students was usefully explored by David Doorey in the context of Canadian employment law courses. Drawing on Twining's exposition of developing separate theories of legal education for lawyers and non-lawyers (Twining, 1967), he particularly highlighted the need to ask *why* a particular course is being taught and what students want and need from a course rather than taking the same approach as with law students (Doorey, 2007).

Morris (2007) suggests that the goal in teaching law to land and property students is both to be able to work intelligently with lawyers, *and* the goal of keeping themselves out of trouble through the practice of 'preventative law' (Ridley, 1994). We are, for reasons of practicality and accessibility, into the realms of 'translating' the law rather than having students make extensive use of primary sources. The materials are reduced to a core. Although there are dangers in this (Ward and Slater, 1990) there is a considerable need (regardless of an academic ideal), in many of the legal subject areas, to get across a level of 'prophylactic law' - a base level of knowledge to avoid dangerous or expensive mistakes in professional life (Soetendorp, 1999 and Soetendorp and Byles, 2000) and with health and safety this can literally mean the difference between life and death.

These, then, are some of the issues which the teacher of law on a non-law course needs to address. Subject benchmarking statements, professional guidance and the experience of colleagues have been drawn on to determine the mix of substantive knowledge and the transferable (NCIHE, 1997) research and evaluation skills needed which also seek to support ' … diversity, flexibility and learner autonomy' (Hinett, 2002). Also, whilst not teaching future lawyers, there are key points to be transferred across the disciplines, such as :

- where to find the law
- that the law is constantly changing (Soetendrop, 1999)
- the ability to identify legal issues (Cownie, 2004)
- getting beyond the surface learning of facts, through to a deeper understanding (Marton and Säljön1976 and Meyer and Land, 2005).

Vocational law courses / modules which have often avoided the final issue and have provided a diluted delivery of facts, without the contextual framework offered to law students (Broadbent, 2005), which does little to develop understanding and proliferates the idea that law can be a dry set of unambiguous rules.

4 Methodology

In considering, through personal experience, colleague input and data, the short comings of current teaching, analysing and reflecting on the position and developing changes, the evolution of teaching methods and materials is broadly following an iterative process of change under action research methodology, first explored by the Prussian American psychologist Kurt Lewin (1946) and later developed in an educational

[11] A defence or rejection of black letter teaching for *law* students is left for others to consider.

context by many, notably the highly politicised Brazilian left wing educator Paulo Freire (1971) who particularly developed student centred education from its inception with Jean-Jacques Rousseau (1762), the prolific Swiss philosopher. It can be quantified as a form of systematic enquiry resulting in a direct impact on an educator's practice (see also Glanz, 2003).

A methodology on data collection is not provided due to the early stage in the formal analysis of results, which will require more detailed testing to assess beyond the, none the less valuable, impressions which have been garnered.

5 Teaching Practice

The remainder of this paper relates to the attempts to improve the engagement of students and the effectiveness of module delivery. In addition to the self evaluation of the author and peer review, a pilot study of student perception and understanding was carried out. As health and safety law is a relatively small part of any module, there is limited formal examination.

5.1 Lectures

That lectures are not the perfect mechanism to disseminate information and for the effective assimilation of that information is not a new assertion (Gibbs and Habeshaw, 1996), and much has been written on ways to enhance their value and effectiveness (Jenkins,1992; Gibbs *et al*., 1992; Fry *et al*., 2003 and, particularly enjoyably, Bligh, 1998) in terms of engaging interest, maintaining concentration and imparting knowledge, or signposts to acquiring knowledge and skills (Cain, 2007). And an over-emphasis on the regulatory nature of health and safety law can do little to ameliorate some of the most notorious shortcomings of the lecture model. Although keen, then, to develop effective ways of engaging and educating non-law students, the dissemination, or at least introduction, of a base of information is still most effectively done through the lecture and although direct reference to primary sources does not hold a central position (Carrington *et al*., 1995) for the education of non-lawyers, an explanation of the existence, mechanisms, facts and points of law comprising these primary sources of law still underpins the curriculum.

5.2 Notes

In addition to copies of the lecture Powerpoint, a 130 page book has been produced, with short outlines of around 150 cases - *Health and Safety Casebook : key cases from 1837 to 2012 with particular reference to the land-based industries* (de Silva, 2012).

Although these notes do not obviate the requirement that students refer to text books and, on a more practical level, the Health and Safety Executive website,[12] there is a limited requirement for them to refer directly to primary sources in this element of their studies.

[12] www.hse.gov.uk.

5.3 Case based teaching of health and safety to non-lawyers

To try to address the problems encountered in teaching health and safety law to non-law students in a largely lecture based environment - 'fear' of law, disengagement with the phrase 'health and safety' and the like - cases have been introduced as a starting point to learning, in contrast with an earlier approach where the basic legal provisions were disseminated through lectures. Whilst not going into the detail of the casebook method of law teaching common in American law schools,[13] the aim is for the student to appreciate the *relevance* of their legal studies, and to enable the lecturer to move away from too formulaic an approach of talking through the legislative framework, much of which can be provided in note form and with links to further reading. It is hoped that this helps to make materials more accessible, and gives purpose and focus to private study (Monseau, 2005). Morris (2007) considered that students responded to case studies 'perhaps for [their] vivid exemplary or story content.'. This also clearly keeps in mind the key issue of what the *purpose* of the teaching is and what one is trying to achieve (Jacobson, 2011).

Case studies have more usually been introduced after a body of law has been set out in a lecture, addressing none of the problem issues raised above and resulting in students failing to engage before they ever get to assimilate the information and attempt to reach the higher level educational objectives of analysis, synthesis and evaluation (Bloom, 1956 and Anderson and Krathwohl, 2001) to apply their knowledge. Of course, basing studies exclusively on cases could leave gaps of coverage and, indeed, balance (Cownie, 2002) but they have proved a useful base for establishing the importance of teaching about health and safety law and providing a practical meaning (Chan *et al.*, 2002).

Several scenarios from law reports are given to read before coming to the lecture. A range of questions relating to the case studies are also given, to raise questions and to prompt independent study. The applicable *law* is not, however, given ahead. The cases are reviewed in the lecture with a review of the law at that stage. This has helped students understand how the law applies to a very practical situation or incident.

6 The Cases

Cases which have been used this year include the following. The reasons for choice are indicated.

Armstrong, Douglas John - Inquiry into the circumstances of the death of, under the Fatal Accidents and Sudden Deaths Inquiry (Scotland) Act 1976[14] Sheriff Court

This involved a fatality after a quad bike accident on a rural Scottish estate. An overloaded bike was being used by a casual, untrained worker to do the pheasant feeding rounds. He arranged to cover for a sick friend. No risk assessment resulted in a lack of means of communication, no check on competence to ride a particularly

[13] See Kaufman, 1998.
[14] Selkirk Sheriff Court, 28th August 2008

powerful quad bike, no helmet, no lone working policy, no route map. The deceased was not found for two days. The matter resulted in a conviction of the Trust who held the estate under the Health and Safety at Work, etc. Act 1974. There was an action against trustees personally which was later dropped but which added legal interest in terms of business structure and the personal responsibility of office holders.

British Railways Board v Herrington **[1972]**[15] House of Lords

This well known case involving a child being seriously injured when trespassing on British Rail land resulting in a successful occupiers' liability action was chosen to indicate that the responsibility of employers may result in civil action. It also stresses the need for awareness of members of the public who might be on the premises, and ties in to other studies on occupiers' liability and the development of law in that area with the resultant introduction of legislation.

R v Morris, Marshall & Poole **[2011]**[16] Crown Court

This case resulted in a conviction of a company under the Health and Safety at Work, etc. Act 1974 following the death of a 79 year old freelance 'odd job' man. He fell from a roof whilst carrying out property repairs and maintenance for a letting agent. There was little evidence of a risk assessment. This case discussed risk assessments and highlighted the level of responsibility towards workers who are *not* employees.

R v Velcourt **[2011]**[17] Crown Court

A 21 year old harvest worker died when the extended grain spout of his combine harvester contacted an 11,000 volts overhead power line. He was working with one of the biggest, tallest machines on his first commercial harvest. Velcourt Ltd were found to have failed to adequately inspect, monitor, supervise or audit health and safety management at the farm or to ensure that the farm manager received adequate health and safety training.

The case shows the importance of risk assessment and adequate training.

R v British Sugar plc **[2005]**[18] Crown Court

British Sugar plc and transport contractor, VM Plant Ltd, were convicted after an office worker was run over by a shovelling vehicle at the firm's factory in Suffolk. British Sugar admitted failing to ensure that workers were not exposed to risks to their safety. In particular, it failed to adequately segregate pedestrians from areas where vehicles were in operation

Despite a good health and safety record before the accident, within a month another employee had been killed in a boiler room explosion. This prompted a major health and

15 [1972] AC 877, [1972] 1 All ER 749
16 Mold Crown Court, sitting in Chester Crown Court, 20th December 2011, ref. T20110335
17 Salisbury Crown Court, 17th May 2011
18 Bury St Edmund's Crown Court, 8th February 2005

safety review where British Sugar found a gap between training and ensuring that processes were actually being followed, and also a reliable and efficient method of data gathering with regard to reported incidents such that management could regularly review and pick up areas for concern.

The case highlights the point that it is not just those operating hazardous machinery or working with livestock, etc. who are at risk.

R v JMW Farms Limited **[2012]**[19] Crown Court

Only the second conviction for corporate manslaughter under the 2007 Act was brought after a fatality on a pig farm in Northern Ireland. The death occurred when a feed bin was balanced on the prongs of a fork lift truck being driven by one of the company's directors. The bin was not fitted for the truck in question and it fell, crushing a 45 year old farm worker. This case gives a contextual backdrop to an introduction to the Corporate Manslaughter and Corporate Homicide Act 2007 and was heard just in time for the final 2011/12 teaching session and will be explored in more detail in future years.

Uren v Corporate Leisure **and** ***Ministry of Defence*** **[2011]**[20] Court of Appeal

Uren involved a young serviceman rendered paralysed after diving into a paddling pool head first whilst playing organised games on a 'fun day'. The case is useful, in particular, for Smith LJ's consideration of risk assessments and for the position where an employer sub-contracts an activity to another. The Ministry of Defence were the employer, Corporate Leisure were an events organiser running the 'fun day'. The trial judge's decision that, although proper risk assessments were not carried, the risk was small when balanced against the social benefits of the day was rejected and the case was remitted for re-trial.

Walker v Northumberland County Council **[1995]**[21] High Court, QBD

This case, involving a social service manager, is important as being the first to establish that an employer can be held liable for psychological injury to an employee caused by work related stress. The judgment underlined the employer's duty of care to provide safe systems of work in respect of occupational stress as well as other hazards, and to take steps to protect employees from foreseeable risks to their mental, as well as physical, health.

Whitehead v Trustees of the Chatsworth Settlement **[2012]**[22] Court of Appeal

A gamekeeper shot himself in the leg when he slipped whilst carrying a loaded (although broken) gun. The employer was held to be *not* liable - they could clearly evidence that instruction and information on good practice (i.e. not having the gun loaded and ready to shoot) had been provided, with regular review and staff reminders.

7 Has it made a difference?

This style of teaching has been taking place for two years, 2011 and 2012, following many years delivering the outline health and safety provisions in a rather more pedestrian style. It is intended to build in formal testing of this element whereas currently the summative testing is relatively limited due to health and safety comprising a relatively small part of an overall module, or non-examinable briefing. At this stage, however, although that detailed testing has not taken place, three means of assessing effectiveness have been used. Firstly, anecdotal review by the lecturer, comparing student interest in class and engagement with pre-reading. Secondly, peer review of a lecture by a colleague, particularly assessing student engagement by the volume and questions and answers from the student group. And thirdly, a small study of student feedback on their attitudes to and understanding of the health and safety element of the module (rather than just overall module feedback) has been sought this year, with input both before and after the relevant lectures and tutorials.

Self and colleague evaluation is such that, in comparison with other law lectures, the number of students completing the pre-reading and consideration of the cases, as judged by participation and questioning in class, is higher than usual. Student interest is clearly sparked by the combination of (a) the fact that they are looking at 'real' court cases and (b) scenarios with which many of them are familiar.

Before the case-based health and safety lecture and tutorials, questionnaires asked for a statement of students' practical experience, level of health and safety training and views on the importance of health and safety training. Before the sessions over 50% of students indicated that they thought that a knowledge of health and safety practice was important but not health and safety law. After delivery they were asked about learning and any changes in perception. Feedback from these surveys unsurprisingly indicates enhanced perception of the need to understand the law and to take health and safety seriously. It was surprising, however, how many indicated, on paper at least, that *before* the sessions they were fully aware of the importance of this area. There is no formal data from previous years but the author and other staff are clearly cognisant of the lack of interest and dismissal of the subject in former years. This has coincided with increased publicity in the agricultural and rural practice sector of the concerns.

Quantitative data will be collated for a follow up paper on results of tests in health and safety law.

8 Conclusion

The case studies show how the use of real situations can trigger an appreciation of relevance and pique interest to explore the underpinning law, forming a basis on which to develop more technical studies.

The teaching of health and safety law to an academically diverse range of students whose abiding interests might lie well outside legal studies requires careful consideration, a willingness to try a range of teaching and assessment ideas and the grace to alter and abandon methods which fail to engage or prove effective.

It is hoped that the exploration of a case led programme has enhanced the delivery of health and safety information at Harper Adams and may provide some ideas for others.

9 Acknowledgements

Thanks are extended to the Agriculture Safety Section of the Health and Safety Executive, particularly Liz Evans, Her Majesty's Inspector of Health and Safety, for her continuing support of the teaching of health and safety principles at Harper Adams, and for her valuable input with regard to materials and case studies arising for her daily work.

Online Pedagogy for Construction Law in UK Higher Education

Jennifer Charlson[1]

[1]Built Environment, School of Technology
University of Wolverhampton, WV1 1LY
United Kingdom

Email: J.Charlson@wlv.ac.uk

Abstract:
The UK higher education sector is contemplating the opportunity of online learning. The challenges include delivering quality and cost-effectiveness while meeting student demands for flexible learning.The author critically reviews key UK higher education online learning reports and online pedagogy literature and applies them to a first year undergraduate Construction Law module currently taught on campus using a mixture of lectures and tutorials. The module aims to develop understanding of the English legal system, law of contract and to introduce key procurement approaches, tendering procedures and forms of contract applicable to building projects.The author has the additional insight gained by completing a "Learning How to be an Online Tutor" in-house course which was taught entirely online. A University Online and Distance Learning Project Director was interviewed about the University's strategy and plans for online and distance learning. The current module students who are studying for an HNC in Building Studies were surveyed both in class and online about their learning experiences and possible online study. The author outlines the implications for the design of online learning including asumptions, virtual learning environment, online academic material, synchronous meetings and non-academic support. The paper concludes by considering online learning from student, academic and university perspectives.

Keywords:
construction law, online pedagogy , UK higher education

1 Introduction

The UK higher education sector is seeking to expand its online learning provision. This is driven by universities' aspiration to increase their reach beyond students in their immediate geographical area and students' needs for more flexible learning. The UK higher education online learning reports reviewed indicate that the sector has so far only made limited progress.

The author was tasked with designing an online version of a first year undergraduate Construction Law module. The module forms part of the HNC Building Studies course which aims to develop students with a technical understanding of the construction industry.

The course is delivered only on a part time basis over two years. As such students have the opportunity to attend this course through day release from their relevant day to day employment. The planned delivery of the Construction Law module online is to give the students more study flexibility.

The review of online pedagogy literature analyses and summarises why online pedagogy is different, widening participation, online tutor training, virtual communication tools and their role, virtual learning environments and collaboration and online support.

As the University of Wolverhampton is expanding its online provision, it has appointed an Online and Distance Learning Project Director. As part of this research he was interviewed about the University's strategy and plans for online and distance learning.

The 21 current Construction Law module students who are studying face to face on campus for a HNC in Building Studies were surveyed both in class and online about their learning experiences and possible online study.

The author outlines the implications for the design of online learning including asumptions, virtual learning environment, online academic material, synchronous meetings and non-academic support.

The papers concludes by considering online learning from student, academic and university perspectives. It also looks to the future of higher education online provison.

2 Online learning for UK higher education

2.1 Review of key reports

To place online learning for UK higher education in context, the following key reports since 2008 are reviewed in chronological order:

- *"On-line Innovation in Higher Education"* by Professor Sir Ron Cooke, Chair of JISC Board Submission to the Secretary of State for Innovation, Universities and Skills dated 2008
- *"Study of UK Online Learning"*: Report to HEFCE dated 2010
- *"Collaborate to compete. Seizing the opportunity of online learning for UK higher education"*: Report to HEFCE dated 2011

The re-occurring themes are then analysed.

2.2 *"On-line Innovation in Higher Education"*: Submission to the Secretary of State for Innovation, Universities and Skills dated 2008

Professor Sir Ron Cooke was Chairman of JISC, the UK's expert on information and digital technologies for education and research.

In his submission, Cooke (2008, p.3) set out the challenge that *"the UK should, and can, be world leading in on-line learning".* He lamented (p.10) that

 ISBN: 978-1-84219-840-7 .

> *"In particular the UK is not doing enough to provide a more or less complete on-line educational experience to students who, for a variety of reasons (economic, lack of time, geography) cannot enjoy a conventional campus based learning experience. This is especially true of students where demand for higher education outstrips supply such as the emerging economies of South East Asia and South America and those developing countries that are likely to become increasingly important over the next 15 years. Here the UK is currently doing very little under the excuse of having tried it once (the UK e-University) and failed."*

There is however an example of success although it is not in the UK. The Open University of Catalonia opened in 1994 as the first entirely online-based university. It has since grown to more than 46,000 students. Bradwell (2009).

Professor Cooke's recommendations included that the UK must have a core of open access learning resources organised in a coherent way to support on-line learning by all higher education institutions.

2.3 "Study of UK Online Learning": Report to HEFCE dated 2010

White et al. (2010) were commissioned by HEFCE in order to gain a broad overview of the current UK provision of higher education (HE) level online distance learning (ODL). (The Higher Education Council for England (HEFCE) distributes public money for higher education to universities and colleges in England and ensures that this money is used to deliver the greatest benefit to students and the wider public.)

From the data collected, the study observed the following trends:

- Almost all of the ODL courses identified could be described as continuing professional development;
- the vast majority of ODL offered by HE institutions is at postgraduate level;
- Although the number of first year undergraduate courses was relatively high (approximately one third of the total), most of these were short standalone courses, typically offering 10 or 20 credits towards an HE award

The study also found that there is no reliable or accurate consolidated source of information about ODL courses offered in the UK that is readily available to students, or other parties, interested in finding ODL programmes. Much of the information on ODL currently remains "hidden" in labyrinthine institutional websites.

During interview, the study identified some common themes including (p.2):

- *"recognition of the requirement for low student-tutor ratios, and regular feedback and assessment points to ensure that students are engaged and retained;*
- *The need to address the challenge associated with "change management"; e.g. supporting the changes necessitated by the need to encourage academic staff to shift emphasis away from content dissemination towards facilitating more independent and activity-based learning;*

- *The importance of understanding the expectations of ODL students in full-time work and appreciating that their motivations, needs and aspirations may differ significantly from traditional campus-based students. The inherent advantages of ODL as a mode of delivery for students in full-time work were identified."*

A key finding was that it is student and staff support, programme development, administrative processes and business strategies that are currently seen by many as the barriers to growth of the UK OLD sector. The study also found that institutions currently seeking to expand strategically their ODL provision were looking to centralise some elements of their ODL activities, in particular student support, development of supporting resources, learning technology support, and general management and oversight of such programmes.

One of the universities interviewed advised the report's authors that staff need support in assessing whether they have considered all relevant issues including data protection and intellectual property rights.

Regarding the institutional experiences of online distance learning which drew on the university interviews and experience of the report authors the study found:

- All of the institutions interviewed pointed out that the type of high quality ODL they offered was not cheap to develop or to deliver.
- Reconfiguring academic roles (p.46), *"The most significant challenge however, in terms of institutional culture change, is not staff acquiring new technical skills but in the shift in teaching approach ODL requires. With the content transmission elements of teaching increasingly handled by online materials or pod/vodcasts, teaching online often takes a more often takes a more mentoring or facilitative role."*
- It was recognised that ODL is still evolving technologically, pedagogically and in terms of business models.
- Quality and consistency could also be improved by centralising the production of supporting materials to ensure that students and tutors are properly supported in their ODL activities. Such supporting materials include: inductions, Frequently Asked Questions, technical guides, learning support guides, teaching support guides, online etiquette tips, study and research skills. These resources are time consuming to create and require regular and laborious updating.

2.4 "Collaborate to compete. Seizing the opportunity of online learning for UK higher education": Report to HEFCE dated 2011

The Online Learning Task Force was established in mid-2009 by HEFCE and was asked to address how UK higher education (HE) might maintain and extend its position as a world leader in online learning.

The Online Learning Task Force Chair recognised in her introduction to the report (HEFCE, 2011):

- Developing and adopting appropriate pedagogy is slower than technological change. Organisational change that is needed alongside this takes even longer.
- The international market for online learning is growing rapidly although estimating its size remains a challenge.

- Similar opportunities for enhanced flexibility apply within the UK as students seek more work-based, flexible and part-time opportunities to fit work and learning opportunities into their lives.

Regarding student diversity, demand and expectations (p.10), *"Online distance learning (ODL) provides students with the flexibility to study at their own pace, in their own time and at a location convenient to them."*

In considering UK competitiveness, the report notes that

- Business lessons from unsuccessful online ventures include
  - Clarify the purpose: institutions need to know what they hope to achieve from online learning ventures
  - Understand the market and what students want: from the outset there needs to be clarity about the markets in which the venture will operate
- *"We have become more and more conscious that online learning is not a cheap option."*(p.14)

Considering strategy, processes, culture the report recognises that

- Mixed teams within institutions represent a key contribution to success. Academic and subject expertise, with learning technologists, pedagogic experts, and content specialists (e.g. librarians) working closely together is recommended.
- A major concern for students in online learning is the possible lack of personal contact with their tutors and fellow students. HE needs to enable students to learn collaboratively online with appropriate pedagogies, training and availability of technologies.
- There are many sources of quality materials, content and tools, including private sector publishers and online educational providers such as Pearson.
- Wider adoption of open educational resource approaches to online learning raises complex issues of copyright and intellectual property.

One of the case studies identified that students learning in cohorts perform better than learners following their own personalised track. This does however, constrain flexibility in the timing of course delivery.

2.5 Summary

In the reports, the following themes re-occur:

1. The UK should be world leading in on-line learning in a rapidly growing international market.
2. Despite its benefits having been identified, delivering online learning is difficult and there seems to have been limited progress in its provision.
3. The inherent advantages of online learning for students in full-time work seeking more work-based, flexible and part-time opportunities have been identified. JISC InfoNET, (2008, p.13) identified the drivers for e-learning approaches as including *"Meeting the 'new geography' of education – staff and students are physically and socially distributed and wish to pace participation*

according to personal circumstances. Flexibility in 'time and place' is essential."

4. The need to address the challenge associated with "change management"; e.g. supporting the changes necessitated by the need to encourage academic staff to shift emphasis away from content dissemination towards facilitating more independent and activity-based learning
5. Mixed teams combining academic and subject expertise with learning technologists, pedagogic experts, and content specialists (e.g. librarians) working closely together are recommended.
6. Quality and consistency could be improved by centralising the production of supporting materials.
7. Online learning is not cheap to develop or deliver. Moreover, the costs can be difficult to calculate because *"Cost models for staff time are complex; for example, most courses still use a contact model to calculate staff costs, despite the evidence that virtual 'contact' can be equally if not more beneficial to learners."* Association for Learning Technology and Technology Enhanced Learning Research Programme (2010, p.14).
8. Although recommended, the wider adoption of open educational resource approaches to online learning raises complex issues of intellectual property.

These reports prompted the author to research the University of Wolverhampton's online provision. Due to the University's expansion of its online provision, it has appointed an Online and Distance Learning Project Director. He was therefore interviewed about the University's strategy and plans for online and distance learning.

In addition, current students were asked whether they had previously studied online and if they would, in the future, choose to online study.

3 Online Pedagogy

This section reviews online pedagogy issues which are then summarised.

3.1 Online is different!

The following section explores the factors that make learning online different.

> *"The rise in popularity of distance education programmes, taught through web-based media, belies the difficulty in preparing, delivering and studying on such programmes….The technology (ICT) used to facilitate distance learning requires an increased level of learning discipline and motivation, particularly as using new technology at the same time as engaging with a new subject material can be difficult."* (Croft et al. 2010, p.27).

For example, *"students and teachers react to new educational technologies with varied emotions ranging from enthusiasm to disabling fear."* Collins (1999 cited Rovai and Hope 2004, p.2).

This prompted the author to ask students how they rated their IT competence and how often they used the internet.

Salmon (2004) and Jacques and Salmon (2007) note that most online tutors come from face-to-face teaching where they can rely on personal charisma to hold their students' interest and read their body language. Switching to online is a big challenge.

Moreover, Garrison et al (2000) also observe that traditionally, educational interactions have been based upon oral communications between and among teachers and learners. Oral communication tends to be fast-paced, spontaneous, fleeting, and less structured than text-based communication. Socially and emotionally, face-to-face oral communication is a rich medium. In contrast, written communication might be termed a lean medium, in that much of the information that creates and sustains the group dynamic of face-to-face groups is simply not transmitted.

Jacques and Salmon (2007) have identified that in asynchronous online group interaction, the written word replaces speech and visual cues leaving a record of proceedings. The audit trail does have its disadvantages as Salmon (2004, p.20) warns *"the online environment is such that interactions are rather public and recorded for all to see. Tardiness, rudeness or inconsistency in response to others tend to be forgiven less easily than in a more transient face-to-face setting."*

Newman et al. (1997 cited Garrison et al 2000) found significant differences in critical thinking between online conferences and face-to face seminars. Online conference students were less interactive but critical thinking was higher.

Sikora and Carroll (2002 cited Rovai and Hope 2004) reported that online higher education students tend to be less satisfied with totally online courses when compared to traditional courses but *"Positive comments regarding the fully online course centred on the value of reflective thinking and the extra time to process information …. The extra time to process information allowed students to give more in-depth answers and promoted critical thinking skills."* (Rovai and Hope 2004, p.9).

A study by Hopson et al. (2001 cited Salmon 2004) noted that the role of teacher was transformed *"As the students began to use the technological resources to manage their learning, the role of teacher was transformed from lecturer to guide."*

3.2 Widening participation

> *"Universities are dealing with an increasingly diverse population of students who approach university in all stages of their lives and who will require different ways of learning."* (Bradwell 2009, p.36).

JISC InfoNET (2008) recognises that e-Learning offers opportunities to support learners with a range of learning difficulties or disabilities in ways which would simply not have been possible in the past.

Online learning has the potential to reach students who might be unable to attend an institution formally. However, according to the Office for National Statistics, those with no formal qualifications are the very people least likely to have an internet connection in their home. (Bradwell 2009).

Current students were therefore asked whether they had a computer with internet broadband access to study.

In summary, JISC InfoNET (2008, p.24) argues that *"The use of e-learning has undoubtedly widened participation in UK HE, be this participation by overseas students who would not previously have been able to attend courses in the UK, by professionals who need to fit study into busy working life, or by groups of 'non-traditional' learners who form the target of government widening participation strategies."*

3.3 Online Tutor Training

The University of New South Wales (2012) website displays many interviews including case studies to help teachers to gain a working understanding of successful online teaching pedagogies.

"Feedback shows it is worthwhile for designers and e-moderators to experience courses from the participants' perspective, enabling needs to be properly anticipated and prepared for as part of the course design." (Jacques and Salmon 2007, p.205).

The author has completed a "Learning How to be an Online Tutor" in-house course which was taught entirely online.

"Currently, with a few exceptions, development of teachers, tutors, facilitators and trainers as e-moderators relies on training in the use of new technologies, typically virtual learning environments (VLEs) rather than new social communication and pedagogical skills." (Jacques and Salmon 2007, p.277).

The most significant insight gained from the course was that successfully teaching online requires different pedagogical skills. For example:

- The most successful e-moderators have some particular skills: supporting learning in text-based communication, weaving, summarising and classifying participants' messages to promote knowledge-sharing and learning and motivating and developing learning groups without physical meetings. (Jacques and Salmon 2007).
- Continual tutor presence, characterised by short messages acknowledging a student's contribution and followed by guidance, increases student activity. (Garrison et al 2000).Regular feedback is therefore to be incorporated in the online learning design.

However, *"Since faculty promotion and tenure, at present, are largely based on research and publication, some professors zealously feel that they should not take away from their research or writing time to change curricula and pedagogy, for the potential rewards are not worth the time or risk to them. Consequently, many professors still use the traditional lecture as their instructional strategy of choice."* (Rovai and Hope 2004, p.2). Although this is a United States of America perspective, the author believes that this applies in the UK too.

As a consequence, course quality can vary due to a number of factors including available technology and the capabilities of professors who design and teach the

courses. While technology has the great potential to enhance student's active learning, the use of technology requires compatible pedagogy to achieve its benefits. (Rovai and Hope 2004).

3.4 Virtual Communication Tools

As Lewis and Allen (2005) explain there are two main types of virtual communication tools and these enable different types of contacts between students and tutors:

- Asynchronous tools – enable people to communicate at a time that suits them. Examples of asynchronous tools commonly used in virtual learning communities include e-mail and bulletin boards.
- Synchronous tools – enable people to communicate live when they log onto the same system at the same time. Examples of synchronous tools commonly used by virtual learning communities include conference or chat rooms, internet telephony and video conferencing.

Dirckinck-Holmfeld (2002 cited Salmon 2004) has identified 'generations' of online learning environments as:

1. First generation: computer conferencing, asynchronous and text based.
2. Second generation: Web based, still asynchronous but now including more linked (hyper) texts and multimedia resources.
3. Third generation: includes more synchronous communication
4. Fourth generation: looking to the future including virtual reality and mobility.

The students were asked how important it would be for them to receive answers to their questions in real time for example, by a webinar or telephone conference.

The in-house online tutor course was a third generation design and author is undertaking this generation of design.

3.5 The Role of Virtual Communication Tools

Virtual communication tools undertake many different roles. For example:

- Haythornthwaite and Kazmer (2002 cited Hrastinski 2008) argue that three types of communication in particular are important for building and sustaining e-learning communities: content-related communication, planning of tasks and social support.
- Hrastinski (2008, p.2) concludes that *"synchronous e-learning increases arousal and motivation, while asynchronous e-learning increases the ability to process information…. Synchronous e-learning better supports personal participation and asynchronous e-learning better supports cognitive participation."*

Garrison et al (2000) offer a different perspective as shown in Figure 1, they suggest that a worthwhile educational experience is embedded within a Community of Enquiry that is composed of teachers and students – the key participants in the educational process.

 ISBN: 978-1-84219-840-7 .

The model of this Community of Inquiry assumes that learning occurs within the Community through the interaction of three essential elements: cognitive presence, social presence, and teaching presence. The element in this model that is most basic to success in higher education is cognitive presence.

The students were therefore asked whether they benefitted from studying with other students. If yes, they were asked for their reasons for example, social support.

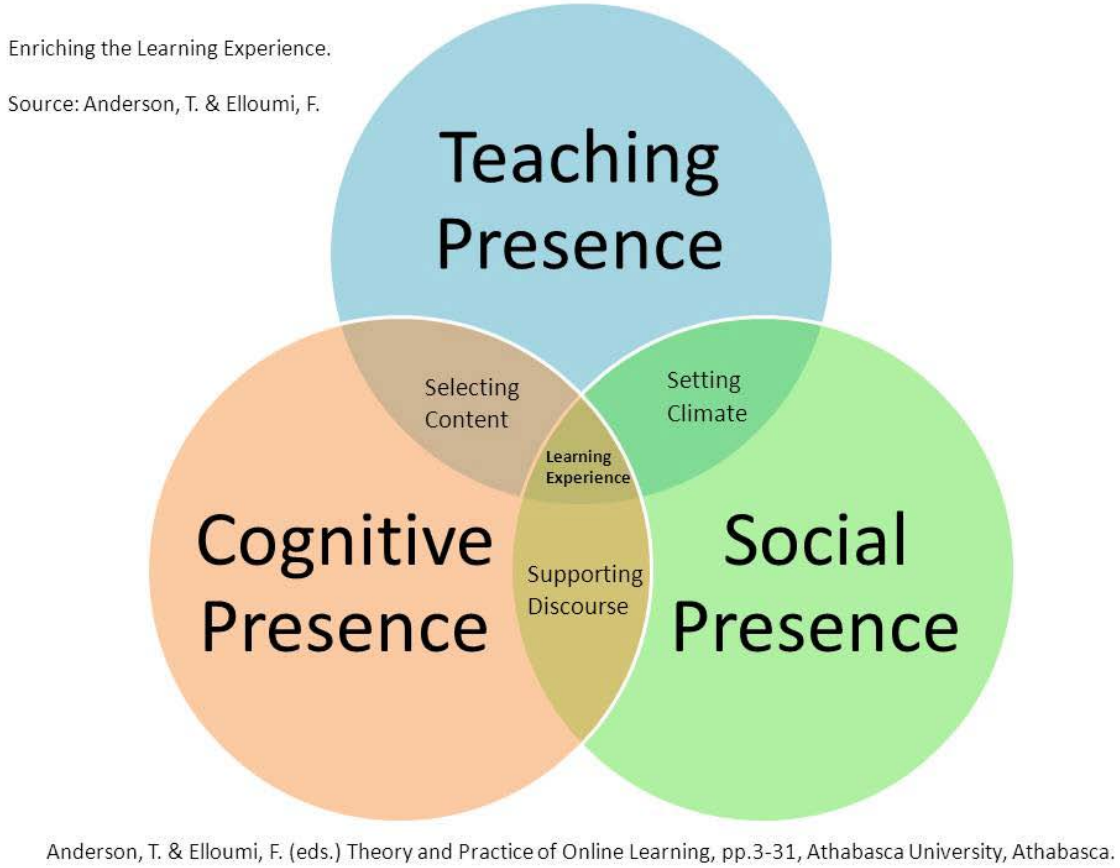

Figure 1. Enriching the Learning Experience
(Source: Anderson and Elloumi, 2010)

Croft et al. (2010) found that there was almost unanimous support for more student-student interaction from the interviewees to provide an 'online student resource where people can talk to each other'. The need to create a form of learning community, where peer contact is enabled and students are encouraged to share their work/thought, was identified as an overarching theme in the research.

The challenge for an online teacher is to consider these concepts in the design and implementation of online learning.

3.6 Virtual Learning Environments and Collaboration

University students are likely to have access to virtual communication tools and other material via a virtual learning environment (VLE) which is defined by INSPIRAL (2001 cited Lewis and Allen 2005) as *"VLEs are web-based toolkits that facilitate learning through the provision and integration of online teaching and learning materials and tools."* There are many commercially available VLEs from which to select. The University of Wolverhampton uses Wolf and PebblePad as VLEs.

Similar collaboration tools are available for example, a wiki (What I Know Is) is an online application of the web that allows everyone to add and edit the content. The process simplifies sharing of content and is a very effective way to exchange information through collaborative effort. (Jacques and Salmon 2007).

The students were asked whether they benefitted from studying with other students. If yes, they were asked for their reasons for example, learning from each other.

However, concerns have been expressed with the use of wikis: accuracy of content, manageability, use of unfamiliar technology, need for careful monitoring by tutors and the time required for participation. (Croft et al. 2010). The author's online tutor group failed to complete their wiki task primarily due to the challenge of group online working to a deadline.

"Another teaching concern is utilizing the collaborative capability of computer conferencing .. What we know about structuring and facilitating higher-order learning in a text-based environment is sketchy and largely intuitive." (Garrison et al 2000, p.97). As an online learning designer, this is a particular concern.

3.7 Online support

Who provides technical support needs to be considered. Lewis and Allen's (2005, p.60) experience is that *"individuals who are new to using virtual communication tools need a certain level of technical support and that this can be extremely time consuming."*

The author therefore plans to form a course team including learning technologists, pedagogic experts and content specialists (e.g. librarians).

The Salmon five-stage model provides an example of how participants can benefit from increasing skill and comfort from working online and networking with each other, and what the e-moderator needs to do at each stage to help them achieve this success. (Jacques and Salmon 2007)

As can be seen from Figure 2, the five progressive stages are:

1. Access and motivation
2. Online socialisation
3. Information exchange
4. Knowledge construction
5. Development

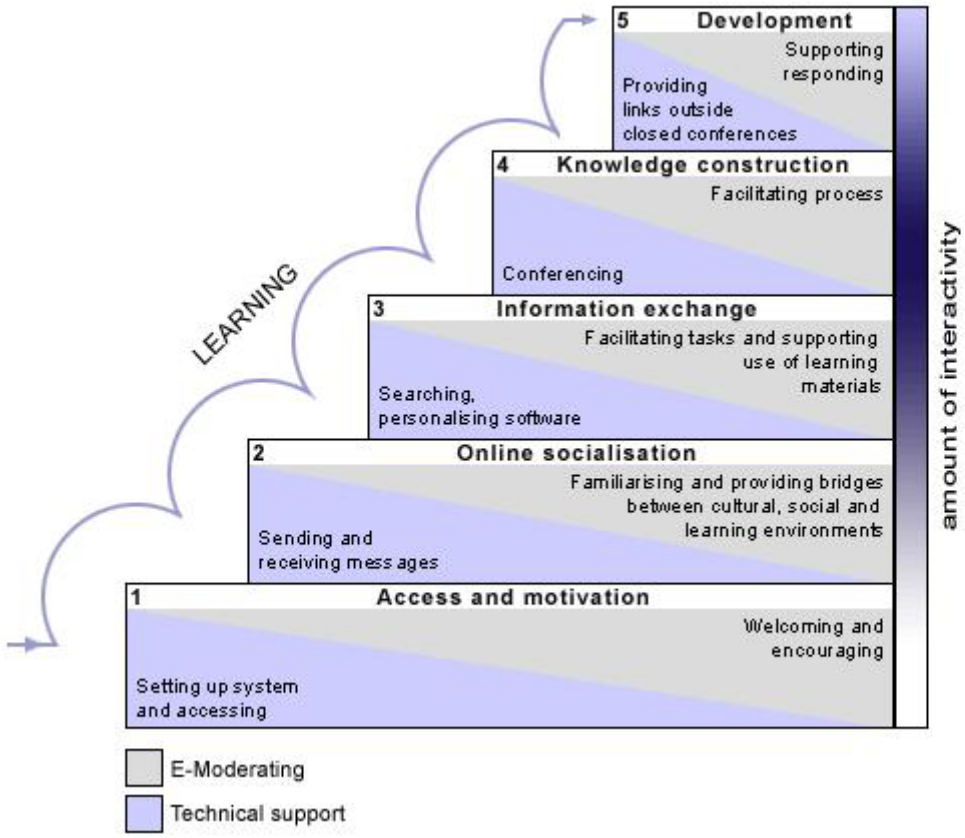

Figure 2. Model of teaching and learning online
(Source: Salmon, 2004, p.29)

Lewis and Allen (2005) find the following activities helpful during the induction stage:

- Introductions
- Narratives
- Technical introduction to the ICT infrastructure
- Ice-breakers
- Ground rules
- Surfacing and discussing hopes and fears of community members

The online learning design is therefore to include induction stage activities.

Some guidelines in online communication practice, often called “netiquette”, are generally regarded as good practice Lewis and Allen (2005).

A good example was Australian Flexible Learning Community (2003).

3.8 Summary

The challenge for the student simultaneously learning a new subject and technology has been identified. Although online learning can widen participation and increase critical

thinking there can also be a move from rich oral communication to a leaner written medium.

For an online lecturer the importance of training on new online social and pedagogical skills as well as new technologies is emphasised. There however, remains the outstanding issue of motivating lecturers to make the change to online teaching.

The differences between asynchronous and synchronous tools and their roles have been analysed. The concept of a Community of Inquiry and the importance of social interaction have been introduced.

Virtual learning environments and collaboration tools were considered. The significance of online support was explained with the aid of the Salmon five-stage model.

In conclusion, it is the author's view that online pedagogy requires a move from *"sage on the stage to guide on the side"* King (1993 cited Bradwell 2009, p.42).

4 Research Findings

4.1 Research methodology

As the University of Wolverhampton is expanding its online provision, it has appointed an Online and Distance Learning Project Director. As part of this research he was interviewed about the University's strategy and plans for online and distance learning.

During the interview comprehensive notes were made and the summary checked for accuracy with the interviewee before inclusion in this paper.

A semi-structured interview format was chosen because as Cousin (2009, p.71) explains *"semi-structured interviews allow researchers to develop in-depth accounts of experiences and perceptions with individuals."*

The first year Construction Law undergraduate module forms part of the HNC Building Studies course. The course aims to develop students with a technical understanding of the construction industry process including the application of management and technology. The course is developed with input from industry professionals to ensure that it is up to date and meets the needs of industry.

The course is delivered only on a part time basis over two years. As such students have the opportunity to attend this course through day release from their relevant day to day employment. It was previously delivered in the evenings.

The course bridges the gap between school and a degree programme. Those students with a merit profile can access a RICS accredited degree course at the second year undergraduate stage.

The 21 current module students who are studying the Construction Law module face to face on campus for the HNC in Building Studies were surveyed both in class and online

about their learning experiences and possible online study. A survey was chosen due to the number of students and potential difficulties in arranging more time consuming interviews.

4.2 Interview with the Online and Distance Learning Project Director

The University of Wolverhampton's Online and Distance Learning Project Director's interview on 7 June 2012 is summarised below.

The University of Wolverhampton's strategy for online learning is to:

1. Increase flexibility for on-campus and off-campus students. Some elements of a course can be studied online and at a distance.
2. Extend our student body in response to possible reduced student numbers due the fees increase. The University will deliver a broad undergraduate and postgraduate programme in the UK, overseas and online.
3. The University has a long tradition of distance learning provision and has decided to remain in this market.

The University currently uses PebblePad as its Virtual Learning Environment (VLE). It has no prescribed view about the synchronous platform provided it is compatible with the VLE.

The biggest headache is working across the University. To combat this there is a committee with representatives from all the Services including: Registry, Quality Assurance, IT and Learning Centres.

"The student experience should be like a train journey with a variety of stops for example, the course advertisement, process of application and enrolment towards the shiny learning experience station finishing with results collection and graduation.
All the stations are in place but not all the lines for example, the online payment per module track is not fully laid yet."

The University already delivers a number of pilot programmes:

- A LLB
- A LLM Common Professional Examination
- A number of other programmes for the School of Education Futures in collaboration with SENCO

The plans for the next academic year are predominantly fully online postgraduate courses including:

- Construction Project Management
- Master of Business Administration
- Public Health
- Military History

The planned online undergraduate level 4 Construction Law module fits in with University's plans to offer more flexibility.

4.3 On campus first year undergraduate Construction Law student survey

The first year undergraduate (level 4) Construction Law module is currently taught on campus using a mixture of lectures and tutorials.

The module aims to develop understanding of the English legal system, law of contract and to introduce key procurement approaches, tendering procedures and forms of contract applicable to building projects.

The 21 current module students who are studying for an HNC in Building Studies were surveyed both in class and on-line about their learning experiences and possible online study.

All the students who attended class on 1 May 2012 completed the survey (See Appendix1). Unfortunately, as this was the last lecture of the module and all the assessments had been submitted, only two students attended.

As there were only two results; they are not representative nor are two people's opinions' generalizable.

Both students:

- Were part-time aged between 26 and 35;
- Considered themselves to be competent with IT and regular users of the internet
- Had a computer with internet broadband access to study
- Neither had studied online before

These students therefore seem to be possible online learners as they considered themselves to be competent with IT, regular users of the internet and had a computer with internet broadband access to study.

They both responded that they benefitted from studying with other students for the following reasons:

- Student 1 wrote *"Yes, social support"*
- Student 2 wrote *"Learning and sharing knowledge, ideas and research with each other. Being with people who understand your learning needs"*

Collaborative learning activities are to be included in the design.
When asked how important it would be for them to be able to receive answers to their questions in real time for example, by a webinar or telephone conference their responses were:

- Student 1 wrote *"Very important"*
- Student 2 wrote *"Quite important, it assists in making decisions quickly"*

If possible, synchronous tools enabling live communication are to be included in the online learning design.

When asked whether they would choose to study online, their responses were:

- Student 1 wrote *"No. I prefer taught lessons."*
- Student 2 wrote *"I may be studying on-line next year, as it fits in with my work pattern, but prefer classroom study as it's easier to absorb information"*

The final comment is intriguing and the original participants could be interviewed to interrogate in more detail the responses given. It is however encouraging that there seems to be a demand for online learning.

The whole class was sent the same survey by email on 24 May 2012 via the module virtual learning environment. There were no responses. The author suspects that this was because it was towards the end of the academic year and many students do not arrange for their university email to be forwarded to their personal email addresses.

Nevertheless, the survey could be re-used next academic year if further data was needed. Also, focus groups could be held with more students to identify common themes from a wider voice.

4.4 Summary

The task undertaken by the Online and Distance Learning Project Director is a challenging one as Cornford and Pollock (2003, p.77) have warned *"attempts to build the virtual university from the bottom up, course-by-course, without reconstructing the basic structures of the university, appear to be very slow, labour-intensive and highly prone to failure."*

The University of Wolverhampton online provision is in line with the findings of White et al. (2010).

The students surveyed considered themselves to be competent with IT, regular users of the internet with broadband access via computer for study. However, neither of them had previously studied online.

They benefitted from studying with other students for social support and learning from each other. They differently valued synchronous interaction with the lecturer. There was a preference for classroom lessons but also an identified need for online study to fit in with work patterns.

5 Implications for design of online learning

This section considers the implications for the design of online learning for a first year undergraduate Construction Law module.

- Assumptions
    - The author makes the assumption that the business case including finance and the market for putting this module online has been passed.

- Virtual Learning Environment
  - The University supports PebblePad as the VLE for online delivery.
  - Include induction stage activities.
  - Devise collaborative learning activities.
  - Incorporate regular feedback.

- Online academic material

  - For example, the main textbook (Ashworth 2012) for the Construction Law module is not currently available online. However, the author recently attended a webinar delivered by the publisher (Pearson). Pearson supports other law textbooks with online exam-style questions with suggested answers, MCQs, flash cards, glossary, legal update and news.

  - To contextualise the Health and Safety Law, Health and Safety Executive's Worksmart videos featuring stories about accidents, near misses and risks to health and safety in the construction workplace can be used (HSE, 2011)

  - *"It may be appropriate to include videoed lectures online to introduce the topic and create a more personalised approach."* (Croft et al. 2010, p.35). As this module is also taught on campus this approach would be adopted.

  - However, beware that online resources can disappear without notice for example, Australian Flexible Learning Community (2003).

- Synchronous Meetings

  - These present two main challenges: IT and timing. The author attended a Webex seminar which offers video, audio and text chat pane connectivity. Initially, she could not hear but this was resolved by the IT help desk. However, students may have IT compatibility and operability issues without IT support. Also, a key driver for online learning is its flexibility and finding a suitable time for a synchronous meeting factoring in students' other commitments and time zone differences will not be easy.
  - *"Students felt video conferencing would not be a viable addition to the course, with issues of cost , synchronicity, availability, personal preferences, technological difficulties/availability, and the constraint of needing to be available at a predetermined time and location all cited."* (Croft et al. 2010, p.50).

- Non-academic support

  - Form a team including learning technologists, pedagogic experts and content specialists (e.g. librarians). For example, develop guides for the new technology and online study skills.

- Liaise with your administration team. *"The importance and quality of support provided by the administrative team (Student Advisers) was found to be high."* (Croft et al. 2010, p.44).

As Salmon (2004, p. vii) argues

> *"Web utopians are predicting virtual universities with very low cost learning and truly effective 'any time, any place' student interaction. They say that the need for expensive campus buildings or large corporate training facilities will disappear along with the requirement for learners to physically congregate. The 'Web-phobes' are very worried that the benefits of learning together may be lost and that it will be a bad day for knowledge, for feelings, for the joys of gatherings and groups."*

It is the author's view that the challenge is to combine the best of both views to create an online pedagogy for Construction Law in UK higher education.

6 Conclusion

This paper concludes by considering online learning from student, academic and university perspectives.

There has been recognition that it can be difficult for students to balance study with work. Online learning facilitates flexible learning and there does seem to be a market for such mode of delivery. Nevertheless, it challenging for students to simultaneously learn a new subject and technology.

However, the transition of existing courses from face to face to online delivery is not straightforward. Online learning has its own pedagogy which is perhaps not familiar to lecturers. Moreover, with the current HE promotion criteria, there is little to motivate academics to change their delivery from content dissemination to facilitating independent activities and learning.

In addition, it is recognised that online provision is not cheap to develop or deliver. With low tutor to student ratios advocated it has to be questioned whether such delivery fits the requirements of higher education funding models. A possible solution is the use of mixed teams including academics, technologists, librarians and administrative support.

The UK higher education sector has grappled with online learning but it can be argued the sector has not yet truly grasped the opportunities. Current provision is not comprehensive and is continuing professional education focused at first year undergraduate and postgraduate levels. Perhaps the change in funding with undergraduates facing higher fees will be a factor towards the development of more online courses.

7 Acknowledgements

The author would like to thank Dr Alison Felce and her colleagues in the Institute for Learning Enhancement, University of Wolverhampton for their shared insights.

Appendix 1

Student Interview Questions

Introduction

As you may be aware, I am researching delivering this module (4CN003 – Construction Law) on-line.
As current students, I would appreciate your responses to the following questions.

Student

- Are you a [full-time]/[part-time] student?
- Age: [18-25]; [26-35]; [36-45]; [46-55]; [56-65]
- Do you consider yourself to be [expert]/[competent]/[novice] with IT
- Are you a [regular]/[occasional] user of the internet?
- Anything else you would like to add about yourself?

Questions

1. Do you have a computer with internet broadband access to study?
2. Have you studied on-line before? If yes, what? What was your experience like?
3. Do you benefit from studying with other students? If yes, what are your reasons for example, social support and/or learning from each other?
4. How important would it be for to you to be able to receive answers to your questions in real time for example, by a webinar or telephone conference?
5. Would you choose to study on-line? What are the reasons for your answer?

 ISBN: 978-1-84219-840-7 .

Practitioner Research: The Forgotten Paradigm in Built Environment Scholarship

Paul Chynoweth[1]

[1]School of the Built Environment,
University of Salford, Salford, M5 4WT,
United Kingdom

Email: P.Chynoweth@salford.ac.uk

Abstract:
This paper introduces a model of practitioner research and proposes this as an alternative paradigm for use within the built environment discipline. It defines the concept in terms of research whose primary purpose addresses the needs of professional practice, rather than theoretical or policy concerns, and which also utilizes the researcher's experientially-gained knowledge as a methodological device. The model's academic pedigree is scrutinized within the context of historical and contemporary approaches to knowledge production. It is seen to draw upon the Aristotlean notion of practical knowledge, and to belong within a long epistemological and methodological tradition, having particular resonances with current approaches to social research, and to recent discourse surrounding the knowledge economy. The paper concludes that practitioner research represents a forgotten paradigm within the built environment, and one which is capable of satisfying the competing demands both for professional relevance, and also for academic rigour.

Keywords:
Built environment, mode 2, practitioner research, qualitative research, research-practice divide.

1 Introduction

The built environment as an academic field emerged from, and is often defined in terms of, the property and construction professions that it has traditionally served (Temple 2004). This vocational focus reflects the origins of the field in the 1960s as being primarily concerned with the delivery of programmes of study leading to admission to the types of profession referred to above (Ashworth 2009, p. 27).

As the field has matured since its early beginnings - and started to lay claim to the status of an academic discipline in its own right (Langford 2009) - it has increasingly engaged in academic research in addition to these traditional teaching-related activities. Despite the vocational orientation of most built environment research *topics*, there is, at least, anecdotal evidence that the *treatment* of these topics by its researchers may, on occasion, be acting as a barrier to engagement by potential stakeholders in industry and the professions.

This so-called research-practice divide is frequently remarked upon by practitioners and policymakers in the field and – despite the obvious sensitivities involved in this - is also the subject of occasional published commentary from within the built environment academic community itself (for example, Koskela 2011). The phenomenon is not unique to the built environment. It has been extensively discussed in the academic literature relating to other professions, for example in nursing (Hutchinson & Johnston 2004) and management (Starkey & Madan 2001).

This paper briefly considers some of the possible causes for the research-practice divide in a built environment research context. It then defines a notion of practitioner research and proposes this as one mechanism by which the gap might be closed. It explores some of the epistemological challenges presented by the concept and proposes solutions based on the adoption of some alternative approaches to research methodology within the discipline.

2 The Research-Practice Divide

2.1 Criticism of Academic Research by Practitioners

A criticism frequently levelled at academic research by practitioners is that it displays a naïveté about the nuances and complexities of the subjects being addressed (Reed & Procter 1995, p. 3). Because of this, research may be dismissed as lacking in credibility by a practitioner audience if it is seen as over-simplistic, or focusing more on the theoretical preoccupations of an academic audience, than on the actual concerns of its purported end-users in the professions.

Such criticisms might arise for a number of reasons. Most obviously, it might simply be that – as professional academics - those undertaking the research lack the necessary familiarity with the professional environment to enable them to fully understand it, and therefore to establish a meaningful dialogue with practitioners.

Alternatively, as many built environment academics do have at least some background in relevant areas of practice, the problem might often be more to do with the demands – or, at least, the perceived demands – of the research environment itself. In relatively new and emerging fields of academic endeavor the conventions of academic research are often modelled closely on those of the traditional natural sciences. This was true of sociology in its formative years and Dainty's (2008) study of articles published in a respected peer-reviewed journal within the field tend to support the view that this is also true of today's built environment research community.

The methods employed within such research traditions emphasize the importance of researcher detachment from the objects of study, and of the importance for science of developing general theories. According to this view, the researcher must, of necessity, remain an *outsider*, and must maintain objectivity by basing their findings solely on neutral observations, uncontaminated by any previous *insider* knowledge.

2.2 Relevance or Rigour?

A closely-related issue concerns the disciplinary priorities of the built environment academic community, and the ways that these relate to those of its associated professions. As the built environment academic discipline has grown to maturity there is evidence that, to some extent, its former practitioner academics may be adopting the mores of their new environment in preference to those of practice. For example, in the context of the construction management (CM) sub-discipline, Murray (2009, p.53) describes the development of "two separate CM communities of practice and cultural norms" and a resulting "stand-off" between its professional and academic branches.

As a consequence of these cultural changes there is an increasing tendency for academics to view research in terms of academic, rather than practice-based, norms. This might, for example, involve defining a research project in terms of current theoretical debates within the academic literature, rather than primarily as a response to a specific problem identified by practitioners. Equally, perceptions about the demands for academic rigour are more likely to lead to reliance on the strict application of formal methods, rather than on seeking solutions to problems via more informal and - it might be argued by the practitioner - potentially more creative approaches.

In this sense the challenge of the relevance gap can be seen in terms of a tension between the practitioner's need for *relevance*, and the academic's need to demonstrate the value of their research work according to accepted conventions of academic *rigour*. The difficulty, in a vocational field like the built environment, is that conventional scientific and outsider views of the knowledge creation process fail to acknowledge – and to build upon - that which is well-known by practitioners in the professional environment, but which is not scientifically proven according to traditional methods.

The notion of *practitioner research* is therefore proposed within the remainder of this paper as one means by which these issues might be resolved in a built environment context. The term is introduced and defined in the next section, and presented as a means of satisfying the built environment practitioner's requirement for relevance in research. The following two sections then explore theoretical and methodological aspects of the proposed approach with a view to evaluating the extent to which it might also be capable of demonstrating the required degree of rigour demanded by the academic world.

3 Practitioner Research

3.1 Two Essential Requirements

At one level the term 'practitioner research' can simply be defined as research which is undertaken by practitioners, rather than by professional academics. Although clearly a valid use of the term, such definitions obscure the substance of what is different between much of the research which is presently undertaken in the built environment field, and that proposed here.

For the purposes of this paper 'practitioner research' in a built environment context is therefore restricted to research projects where practitioner knowledge and understanding

are central to both the purpose and the methodology of the research. Specifically, drawing on aspects of Reed & Procter's (1995, pp. 11 - 31) observations in the context of health care research, it will be described as research:

(a) which defines its purpose primarily in terms of the practice needs of one of the related built environment professions, rather than by reference to the policy or theoretical concerns of the built environment academic discipline, and

(b) which uses the researcher's experientially-gained professional practice knowledge and understanding as a methodological device, both as a direct and legitimate source of data, and also as a tool for enhancing the quality and insight of the analysis.

3.2 Research Purpose

Whilst practitioners see research as being concerned with the resolution of specific problems in practice, the academic world takes a more detached approach. Their priorities are as likely to be informed by "gaps in the literature" as by reference to what is already common knowledge within the professional environment. They are also more likely to take a more theoretical and policy-driven view of the research purpose, seeing it primarily as a means of making a more long-lasting, and context-independent contribution to knowledge, than simply in terms of fixing a particular aspect of practice that is currently malfunctioning.

These differences conceal what is arguably a more fundamental distinction between the two worlds, namely that between research purposes which take either an *insider's* or an *outsider's* perspective. The priorities of the (social science) outsider researcher, and the ways in which these contrast with those of the practitioner are articulated by Reed & Procter (1995, p. 11) in the following terms:

> "For the social science researcher or 'outsider' the aim of the research is usually to contribute to the body of social science knowledge….therefore, practice is only examined for what contributes to an understanding of practitioner action, not practitioner knowledge."

In direct contrast to this, the practitioner's requirement for research is, of course, precisely that it should contribute to the development of practitioner knowledge, thereby enhancing the professional knowledge base and leading to improvements in practice. The suggestion in this paper is that some of the research undertaken within the built environment might usefully define its purpose primarily in terms of the practice needs of the relevant professions. This is therefore a challenge to the academic world to focus aspects of its research work on the development and application of the professional knowledge base of those professions.

3.3 Research Methodology

The second requirement for practitioner research, as defined in this paper, is a methodology which regards the researcher's experientially-gained professional practice knowledge and understanding as a research resource, and which draws unashamedly on this. Following Polanyi's (1966, p.4) familiar notion that "we can know more than we can tell" a significant aspect of this resource will take the form of what he described as

tacit, rather than explicit knowledge. In the language of research it will form a component of the research data, and will also inform the researcher's analysis of those data.

As previously discussed, it is not envisaged that 'practitioner research' will always be undertaken exclusively by practitioners. Where practitioners have the aptitude and the inclination for this, they may indeed choose to undertake research themselves. However, the required practice-based knowledge and understanding might equally be harvested via alternative means. Perhaps most obviously, this might be made available through collaboration between academics and practitioners in order to produce the required synthesis of this resource with the research skills necessary to make effective use of it. In this context what is being proposed echoes what Reason (1988, p. 1) has described as 'co-operative experiential inquiry' rather than a more traditional collaborative arrangement whereby the researcher gathers data from a practice-based research subject for analysis and subsequent reporting back to practice.

A further approach draws on the fact - previously alluded to – that academics in the built environment field overwhelmingly possess significant experience of professional practice in their own right. It follows that the approach advocated here can be undertaken by many academics in the field, even in the absence of collaborative arrangements with existing practitioners. To be effective this might call for continued immersion in, and engagement with, the world of practice, and a proactive approach to maintaining one's professional development and subject knowledge. However, this is arguably no greater a commitment than is already necessary for built environment academics to perform as effective teachers in the discipline.

By drawing on this resource the research can avoid the criticisms of naïveté and over-simplification described above, and can build on that which is already known, rather than having to start from an artificial position of feigned ignorance. The challenge, of course, is to demonstrate that such an approach is also capable of demonstrating the necessary degree of academic rigour demanded by the research community. This aspect is addressed in the remaining sections of this paper.

4 Philosophical Traditions

4.1 Practical Knowledge

On first impressions, the proposed combination of research goals which are pragmatically rather than theoretically determined, and methodologies which draw on experientially gained tacit knowledge rather than detached observation, might be seen to represent something of a challenge to conventional notions of academic knowledge. These notions, according to Barnett (2000, pp. 16 & 17), see knowledge in terms of "ordered conceptual frameworks", an "edifice, having a durable character", or "bodies of knowledge…with systematic strategies to add to those bodies of knowledge through research".

However, he also draws attention to a parallel tradition in western thinking that is as old, or older, than these ideas, and which echoes the concept of practitioner research

proposed in this paper. Rather than seeing knowledge as an edifice which is self-consciously created by external actors, this tradition recognizes that it can also be generated *in action*. Within this tradition the knowledge is seen as embedded within human action, and being inseparable from it.

These ideas were articulated by Aristotle in *The Nicomachean Ethics* where he distinguished the concept of ep*isteme* (theoretical know-how) from those of *techne* (technical know-how) and *phronesis* (practical wisdom). Barnett (1997, p. 12) describes the latter two concepts, collectively, as Artistotle's notion of 'practical knowledge' which he interprets as asserting the legitimacy of knowledge gained through practice.

Barnett also cites the history of western universities as evidence of this alternative tradition of knowledge. He notes that the earliest mediaeval universities were established as "high level professional schools" for vocational training in the law, medicine, and theology and that the emphasis was therefore practice-based, rather than theoretical.

The connection between knowledge and action is not simply of historical interest but has also attracted increasing attention throughout the twentieth century and beyond. In the field of professional education this includes Schön's (1983) seminal work on the *reflective practitioner* with its related concept of *knowledge in action*. In politics and sociology the Marxist notion of *praxis* – often associated with the work of Gramsci (2011) – also draws an intimate connection between ideas and their realization through practical action. In business and education these ideas also underpin Kolb's (1984) concept of *experiential learning*, as well as the practice of *action learning* (Brockbank & McGill 2003). In a research context the latter two business-related practices have obvious parallels with the techniques of action research developed by Lewin (1946) and others.

4.2 The Knowledge Economy

The above discussion demonstrates that there is nothing new in the idea, proposed in this paper, that the process of formal knowledge creation can legitimately draw upon tacit, experientially-generated knowledge from the workplace. Indeed, it might be argued that recent developments have now catapulted such ideas into the intellectual mainstream. These developments were foreshadowed in Drucker's (1968) insightful work, *The Age of Discontinuity*. In this prescient account of future (now present) society he anticipated the effects of information technology, globalization and mass education and introduced the terms "knowledge economy", "knowledge society" and "knowledge worker" into the language.

More recently, the impact of these changes on the research enterprise was famously articulated by Gibbons et al (1994) in terms of a move from *mode 1* to *mode 2* knowledge production. Mode 1 is identified as the disciplinary, theoretical knowledge which has traditionally been generated in universities through research. The authors' thesis is that this is now being displaced by a more dynamic process (mode 2) where knowledge is increasingly generated "in the context of application" as a response to immediate problems identified in the working environment, rather than in universities.

The knowledge so-generated is no respecter of disciplinary boundaries or hierarchical power structures and is said to be trans-disciplinary in character. It will often be produced by transient teams of workers. Significantly it will rarely be formally codified, and will therefore only be apparent in the solution to the problem it was designed to address. The quality of the knowledge so-produced is then evaluated, not by formal academic conventions, including peer-review, but by more pragmatic criteria based on its overall utility.

4.3 Knowledge Management

The significance of Polanyi's (1966, p. 4) concept of *tacit* knowledge to the process of practitioner research has already been referred to on several occasions. Before concluding this discussion, a further related strand of thought, also associated with the development of the knowledge economy, should therefore briefly be introduced. This concerns the detailed consideration that has been given to the tacit knowledge concept in the burgeoning volume of literature on 'knowledge management' that has emerged since the early 1990s.

Like the concept of mode 2 knowledge production, the knowledge management field is also a product of the knowledge economy. As knowledge has grown in importance within modern society it is increasingly being seen as a key asset within organizations, the effective management of which is likely to provide a source of competitive advantage (Hislop 2009, p. 3). Because much of a firm's knowledge resides within the minds of its employees in tacit form this has understandably generated a renewed interest in Polanyi's ideas - by Nonaka & Takeuchi (1995) and others - as well as a recognition of the central role of tacit knowledge in contemporary organizations.

In the context of the current discussion, this recognition of the importance of tacit knowledge within a contemporary body of academic literature is itself significant. The different approaches to the treatment of this intangible concept by academic writers are also of interest, and preface the discussion of methodological traditions in the next section. As demonstrated by Hislop (2009, pp. 18 – 49) these approaches fall into two distinct categories which echo the two parallel views of knowledge production previously discussed, and highlighted by Barnett (2000, pp. 16 & 17).

In the knowledge management field the dichotomy is between what Hislop identifies as an *objectivist* and a *practice-based* perspective of knowledge. The former – which he describes (p. 19) as being "deeply-rooted in the philosophy of positivism" – sees knowledge as objective, capable of existing independently of people in a codifiable form, and privileges explicit knowledge over tacit knowledge, which it regards as less rigorous and subjective. Objectivist approaches to knowledge management therefore typically seek to capture, and to codify, the tacit knowledge of employees, and to convert as much of it as is possible into explicit form.

In contrast, the practice-based perspective might be seen as being synonymous with the idea of *knowledge in action* discussed above. This perspective – which Hislop (p. 33) describes as "an epistemology of practice" - rejects the notion that tacit knowledge can be separated from either the people who possess it, or the practice that gave rise to it. It therefore regards knowledge as both personal and context-specific. Its approaches to

knowledge management therefore shun attempts to generate objective, value-free knowledge and instead focus on facilitating effective communication between employees to enable tacit knowledge to be shared within the organization. Significantly, in common with the notion of practitioner research advocated here, the value of tacit knowledge is recognized as a resource *in its own right, and in its entirety*, without the need to first transform it (or some of it, as parts of it will not be capable of transformation) into a more conventional format.

5 Methodological Developments

5.1 Ideographic and Emic Approaches to Knowledge Production

This *action-based* tradition of knowledge creation therefore has a long history which continues to develop. As has been seen, it is characterized by an attention to the detail and complexity of particular contexts and situations which can only be achieved through long-term and intimate connection with them by the knowledge creator. This, of course, is at variance with the scientific tradition's emphasis on the creation of general theories, undertaken through pre-planned and detached observation.

Nevertheless, this theoretical tradition has its own methodologies which are quite distinct from those employed within the sciences. These are often described as *ideographic*, as opposed to *nomothetic*, and as taking an *emic*, as opposed to *etic* approach to the subject of study. Sayer (2000, p. 3) describes *ideographic* methodologies as being concerned with "documenting the unique", and contrasts this with the general "law-seeking" priorities of *nomothetic* science. Equally, using the terminology which Pike (1954) borrowed from linguistics, an *emic* approach seeks to understand contextual meaning and purpose, and will often be synonymous with an insider's view of a subject. This is quite different from the outsider's *etic* approach which seeks to make sense of particular instances in terms of their relationship to existing theories or frames of reference.

5.2 New Paradigms in Social Research

Historically, ideographic and emic approaches to scholarship have been associated with the humanities, rather than the sciences. However, since at least the early 1980s they have increasingly been adopted within the social sciences. Whilst initially favouring those which replicated the methods of the natural sciences Erlandson et al (1993, pp. 5 - 9) describe a growing disillusionment by scholars with techniques which were not always capable of generating credible accounts of the social world.

This generated a move to what was originally described as "new paradigm research" (Reason & Rowan 1981) which sought to legitimize, within the social sciences, some of the more subjective, researcher-centric methods which had previously been associated only with the humanities. Although having many different forms the iconic version of the emergent paradigm is arguably Lincoln & Guba's (1985) *Naturalistic Inquiry*. In this seminal text they set out (ibid, pp. 39 – 43) an approach to research which seeks "ideographic interpretation" by a "human instrument" through the "utilization of tacit knowledge". They envisage the use of "qualitative methods", "negotiated outcomes"

with research participants and research outputs which adopt a "case study reporting mode".

Today, this new methodological tradition within the social sciences is more usually described simply as 'Qualitative research' - now regarded as far more than an alternative (non-quantitative) type of data collection and analysis in research that otherwise conforms to traditional concepts of the scientific method. Kidder & Fine (1987) describe the latter simply as 'qualitative' (with a small 'q') research in order to distinguish it from the more usual use of the term. Rather, Qualitative research now represents a self-contained paradigm which challenges the notion that natural science methodologies – with their emphasis on the objective measurement of inanimate objects – can meaningfully be applied to the study of people, or of society.

As these ideas have gained increasing purchase within the social sciences there has been an understandable move away from methods which seek to distance the researcher from the research participants, in favour of those which emphasize his or her role as a part of the research setting. As a response to these developments a range of techniques – most notably the concepts of *reflexivity* (Alvesson & Sköldberg 2000) and *bracketing* (Moustakas1994) - have been developed in order to accommodate the close involvement of the researcher with the research setting.

5.3 The Built Environment Context

These developments suggest that the model of practitioner research proposed within this paper can comfortably be accommodated within the now well-established tradition of Qualitative research methodology. Indeed - as is clear from the burgeoning body of literature on practitioner research in health and social care (for example, Sanders & Wilkins 2010) - this is already the case within some professions. The present lack of familiarity with the concept of practitioner research within the built environment discipline might simply reflect a more general lack of familiarity with some of the recent developments in Qualitative research within the wider academic community identified in this paper.

Dainty's (2008) study has already been referred to in this context. He describes his findings as reflecting (ibid, p. 7) an "ongoing adherence to natural science methodologies and reductionist approaches" within the field. In the context of the diversity of approaches that could potentially be adopted he also notes an apparent reliance on semi-structured interviewing by the small number of Qualitative researchers within the discipline. Finally (ibid, p. 8), despite the tradition of reflexivity which exists within Qualitative research, he draws attention to its absence in any of the papers considered within his study. This suggests, as a first step towards realizing the possibilities of practitioner research, that the built environment research community might first embrace many more of the traditions and techniques that are now a routine part of social research in other fields.

6 Conclusions

Despite its vocational origins, it is suggested by some that a research-practice divide might be starting to open up within the built environment field. It has been argued in

this paper that that this may be due to the apparently conflicting demands – respectively from practice and academia - that research must be both relevant, but also academically rigorous. In the built environment, the latter requirement has tended to generate research which satisfies the requirements of the traditional scientific method. Unfortunately, whilst delivering rigorous findings, these approaches have occasionally failed to satisfy the practitioner's demands for relevance. This paper has therefore proposed the notion of 'practitioner research' as being potentially capable of satisfying the requirements for both relevance and rigour. It is proposed, not as a replacement for existing approaches to research within the field, but as an alternative paradigm, capable of enriching the range of methodologies currently employed.

Whilst offered primarily as a response to the practitioner's demand for relevance, the proposed approach has also been demonstrated within the paper to conform to a longstanding, but recently-reinvigorated, tradition of knowledge creation within the academic world. Drawing on Aristotle's ideas about 'practical knowledge' this tradition finds regular academic expression in such concepts as knowledge in action, praxis, reflective practice, experiential learning, as well as action learning and action research. More recently it is seen to have a particular resonance in the current discourse surrounding the knowledge economy, through the concept of mode 2 knowledge production and the ongoing developments in knowledge management. Within academic research the tradition employs methodologies which emphasize the importance of *ideographic*, *emic* and *tacit* approaches to investigation. Traditionally these have been associated with the humanities but, as has been seen, in recent years they have been increasingly employed as a mainstream strand of social research.

With its origins in professional practice it is perhaps surprising that the built environment discipline has not already embraced practitioner research, as has been seen to be the case in other vocational disciplines. For the reasons discussed, this may be due to the relative newness of the discipline, and to its continued adherence to methodologies which are modelled on those of the natural sciences. Nevertheless, practitioner research is proposed here as an alternative paradigm for use within the field. Given the practice-centered backgrounds of many built environment academics, and the long history of this Aristotlean approach to knowledge production, some might consider it more appropriate to describe it as the built environment's forgotten paradigm.

ABSTRACT

The construction industry in the UK produces up to one third of all waste to landfill. This situation has been targeted by the government through landfill tax and commitment. The commitment has used 2008 as its base year and the target is to reduce construction waste to landfill to half the 2008 amount by the year 2012. Using both qualitative and quantitative research this study aimed at identifying specific issues creating waste in construction projects as well as uncovering potential waste solutions throughout the construction process. Waste prevention was identified as the best waste strategy, as by preventing waste the costs and time required for managing waste are greatly reduced. Solutions to waste at the design stage included making waste a higher priority for the client, reducing the complexity of designs, and earlier contractor involvement. Solutions to prevent waste at the construction included use of prefabrication and early communication of design freezes. In all, the target was found to be achievable but would require construction companies to take it upon themselves to implement the proposed solutions. The value of this research is to provide solutions on how to reduce waste and aid the reaching of the landfill target.

Key Words: design, construction, landfill, sustainability, waste.

INTRODUCTION

In general terms waste is unwanted material. Its original purpose has been met and the material is of no further use in its present state or location. In 2011 WRAP found that the construction industry was responsible for a 120 million tons waste which was estimated as being a third of all UK waste. Waste management has generally adopted the approach of finding a way of moving and disposing of this waste through a series of processes. Historically most of the waste has ended up being disposed of via landfill. In the past this was a cheap option for waste disposal. There was adequate space available. This is no longer the case. Surrey County Council (2011) highlighted that in England and Wales landfill sites

[1] l.oyedele@qub.ac.uk
[2] kuburat.olawale@mail.bcu.ac.uk

decreased from 3,400 in 1994 to 2,300 in 2001 with the present number of sites being around 1,500. At present, a high percentage of all waste produced in the United Kingdom is still sent to landfill sites. The volume is increasing to such an extent that other methods of waste management have to be adopted. The view of waste as a resource has further increased the shift away from landfill (Nick Herbert, 2009).

In 1996 the landfill tax was introduced to discourage use of landfill and to encourage recycling. The tax rates, which initially were set low, have subsequently been increased in order to strengthen its behavioural impacts, and more increases are planned. This tax has impacted on the construction industry. In 2000 the DETR found that 24% of construction waste was disposed at landfills compared to 51.2%. In June 2008 the "Strategy for Sustainable Construction" was created. It is a joint industry and Government strategy with an overall goal of enabling England to be world leaders in sustainable construction. One of the key areas of the strategy is waste were the target is to achieve "By 2012 a 50% reduction of construction, demolition and excavation (CD&E) waste to landfill compared to 2008". In the hope of aiding the reaching of this target the objectives of this research are to identify the main issues within a construction project which create waste, as well as solutions to the waste

LITERATURE REVIEW

There is a substantial amount of literature concerning waste within the construction industry. This research will look at waste management towards achieving the government initiative. The waste hierarchy prioritises the different waste management strategies in terms of sustainability with prevention being the best option. It is essential to understand the sources of waste within the construction process. Morris et al (2007) claim that one third of all construction waste can be traced back to decisions at the design period. Ekanayake and Ofori (2000) identified three main categories of waste generation on a construction site namely, materials, labour and machines but highlighted material waste as being of more importance due to the construction industry using mainly virgin materials which are from non-renewable sources. Furthermore they found there to be four chief sources of waste in construction which were design, operational, material handling and procurement (material). In support of this Gavilan and Bernold (1994) identified six source categories of construction waste, with four the same as above. They are design, procurement, material handling, operation, residual and others.

Design Stage

Osmani et al (2007) discovered that architects believed most waste generated during a construction project to be the cause of contractors through such processes as misinterpretation of architects' drawings and specification and on-site logistical and operational activities. In all it was found that designing out waste was considered an ad-hoc activity and architects would only be willing to work with contractors on this process if enticement was provided by clients, mainly through financial incentives. This approach of coordination is supported by WRAP (2008b) whom claim that "It is the contractor who sees where waste is generated on site and who should be able to support the designer in looking for waste within the design". WRAP (2008b) identified processes during the design stage to help minimise waste. These include preventing design variations through understanding the client's needs and the client providing "clearly defined objectives" and designing for site conditions. The need to minimise design changes is supported by Osmani et al (2006) who found, through use of questionnaires that contractors and architects both agreed that late changes due to clients' requirements and design changes were the main causes of waste at the design stage. The

increase in complexity of buildings also affects the amount of design changes. WRAP (2008a) supports this by promoting standardisation of design to reduce complexity. If design changes are necessary all parties involved should be given appropriate and effective notice of them (Faniran and Caban, 1998). Most importantly the design stage should be considered as the stage which offers the greatest opportunity for waste minimisation (Keys et al, 2000). Ofori and Ekanayake (2000) advocated the early involvement of the contractor during the design stage as a means towards waste reduction.

Construction stage waste prevention

One of the main causes of waste at the construction stage was considered by Jones and Greenwood (2003) to be "damage due to mishandling, weather and inadequate storage". Enshassi (1996) claims that having inadequate storage on site can cause waste. However he highlighted that contractors are not conscious of the rewards of providing proper storage. He also recommends having costly materials arriving on site only when needed by providing safer off-site storage. A better material storage solution is Just-In-Time deliveries (Akintoye, 1995). This highlights the need for supply chain management in order to provide JIT production in the construction industry. Vrijhoef and Koskela (2000) state "The basic idea of supply chain management is to recognise the interdependency in the supply chain, and thereby improve its configuration and control based on such factors as integration of business processes. One way to enable supply chain integration is through partnering. Furthermore WRAP (2008a) suggests that engagement with the supply chain can be used to minimise packaging on materials, encourage suppliers to reduce waste at source as well as aiding the setting up of 'take-back schemes' enabling the contractor to return surplus materials to his suppliers. Tam et al (2005) highlight another cause of material waste to be the use of the conventional construction method, which involves a lot of cast in-situ operations. Jaillon et al (2008) discovered that prefabrication can provide numerous additional benefits such as a decrease in time to complete a project and an improvement in health and safety. Material handling was also identified as a construction stage waste contributor, which can be improved through the use of the right piece of handling equipment for the conditions at that time (Cooke and Williams, 2009).

Reuse and Recycling Construction Waste

Faniran and Caban (1998) state "Re-using and recycling waste refers to the reusing and recycling of waste materials, thereby reducing the volume of waste material to be disposed of and discharged back into the environment". To be able to make the most of both waste management techniques it is necessary to segregate waste. This view is defended by (Wimalasena et al, 2009) who believe it is necessary to analyse construction waste so as to better understand the waste problem and help create "targeted recycling programmes". Site Waste Management Plans (SWMPs) help to promote the segregation of waste which allows for the recuperation of materials and also provides a safer working environment (Hill, 2008). SWMPs have now become compulsory on all construction projects of a cost greater than £300,000, within England from April 2008 (WRAP, 2008c). Furthermore WRAP (2008c) claims that the use of SWMPs has reduced the cost of waste management for contractors. In terms of comparison between recycling and reuse of material waste it is better to reuse materials on-site than the recycling of materials off-site, though both are preferable to landfill disposal (Craighall and Powell, 1999). This is down to the facts that re-use on-site saves on transport costs and obviously the cost to recycle materials.

Table 1: Solutions to help reduce waste to Landfill

	Pre-design and Design Waste Solutions	Overall Mean	Architects	Clients	Contractors
1	Early supply chain involvement in design process, giving waste reduction a top priority	4.37	4.50	4.50	4.18
2	Choosing materials for their durability	4.19	4.25	4.50	3.55
3	Longer project programmes and better lead times	4.15	4.17	3.75	4.09
4	Making the Site Waste Management Plan (SWMP) part of the pre-design stage	4.04	3.75	3.25	3.64
5	Submission of Deconstruction plan as part of planning permission application	4.00	2.83	4.00	4.45
6	Training for clients on the benefits of a well defined clients brief	4.00	4.08	3.50	3.36
7	Setting targets for the recycling and reuse of waste	3.96	4.00	3.25	3.55
8	Using partnering as a vehicle for implementing waste management and minimisation practices	3.74	3.42	3.75	4.00
9	Use of supply chain to influence manufacturers to reduce materials waste (i.e. packaging)	3.59	3.58	2.75	3.82
	Construction and Demolition Waste Solutions				
10	Using Off-site Prefabrication	4.33	4.50	3.75	4.09
11	Early communication on design changes between all contract parties	4.15	4.17	3.75	4.18
12	Use of design freezes	4.07	4.33	3.25	3.73
13	Use of quality management to reduce defects	3.93	3.83	3.25	4.00
14	Use of modular construction	3.93	4.17	3.75	3.64
15	Waste efficient procurement (i.e. materials logistic plan Just-In-Time Delivery, etc.)	3.81	4.08	3.75	3.55
16	Instigation of take-back schemes with suppliers for surplus materials	3.74	3.75	2.00	4.00
17	Ensuring the correct handling equipment is available for diverse weather conditions	3.67	3.75	2.00	3.82
18	Using deconstruction instead of demolition	3.33	2.83	4.50	3.45

METHODOLOGY

The approach chosen was to use qualitative research to assist quantitative. It was decided to use semi-structured interviews as the qualitative information gathering technique. In order to get a balanced perspective it was decided to approach the three key players namely, the client, architect and contractor. Personnel with at least 10 years experience were targeted. The quantitative aspect includes a questionnaire survey. The respondents were sourced through use of contact details on the WRAP website of companies that have signed up to the halving waste to landfill commitment, as well as using contacts from the local construction industry. The total respondents numbered twenty seven. Eleven were from contracting firms, twelve from architect firms and only four were from client organisations. The return rate was less than expected with around with nearly 200 surveys sent out via email.

QUANTITATIVE RESULTS AND DISCUSSION

Table 1 below shows possible solutions to reduce construction waste to landfill based on the survey result.

Pre-design and design stage solutions

In terms of overall solutions to the design stage it has been found that waste reduction should be considered early in the design process. This will require an increase in priority, which is unlikely to happen unless it is required by law, provides substantial cost benefit or demanded by the client. In terms of cost benefit it should be highlighted that prevention reduces the amount of waste produced and therefore should fabricate cost savings by reducing costs of unnecessary waste. The choosing of materials for durability is a simple measure in theory. In terms of the client this was the highest ranked solution to waste. This is logical as more durable materials will last longer requiring less change to the clients building and therefore less disruption as well as less expenditure. The increasing of time available for a construction project is unlikely to happen as discussed earlier, though it would most definitely reduce waste production. Shen et al (2002) found that due to heavy penalties for time overruns imposed by the client, contractors are diverted from investing time into environmental management. Lack of segregation of waste, has already been mentioned as an issue impacting on recycling and reuse. However it seems that contractors need to be educated on the benefits as well as the unquantifiable benefit of improving their Corporate Social Responsibility (Tam and Tam, 2005). It is accepted that in some cases segregation is not feasible such as small sites or small projects. In these cases it will be inevitable that waste that could be recycled will end up in landfill.

Construction stage minimisation solutions

The greatest generator of construction waste is the concreting process so any lessening in the amount of on-site concreting equals a reduction in waste (Baldwin et al, 2009). One method of reducing traditional in-situ concreting is to make use of off-site prefabrication. This has been verified by this research with architects, clients and contractors, agreeing that prefabrication are a very effective means of reducing construction waste. Prefabrication is a manufacturing process which takes place in a factory designed for it and thus allows for better control. The repetition of prefabricated units also allows for waste to be removed through refining the process. Furthermore Jaillion et al (2008) found that a 70% time saving could be gained through the use of prefabrication techniques in comparison to in-situ construction. Prefabrication is not without its problems. Due to size of units they are not suitable for small sites. They may be damaged during delivery and more time is required at the early stages of a project to design for prefabrication and allow for production (Baldwin et al, 2009). However this extra time taken before construction can commence could be used to implement proper waste management throughout the project as well as allowing for time to further reduce waste through design. In full traditional methods of construction need to be reduced as much as possible which is further supported by findings that modular construction was ranked fifth as an effective method of waste prevention. The second and third ranked methods of reducing construction waste concern design changes. It has been identified at the literature review, the interviews and validated by the questionnaire as a large cause of waste. The solutions provided to reduce the effects of design changes are the early communication on design changes between all contract parties as well as the use of design freezes. In support Latham (1994) found that if an effective communication network was not defined, then bad practice would continue throughout the construction industry. Therefore it is important to ensure effective lines of communication are set up. Also the use of partnerships would

encourage better relations between disciplines and therefore better communication and understanding. The late changes to designs during the construction phase could be reduced through design freezes. This is otherwise known as design fixity. Cooper et al (2005) explains that design fixity is where the design elements for certain processes are signed off upon agreement and from this point cannot be changed. Design fixity therefore provides the contractor with certainty over the construction process and project which will reduce waste as well as keep the project on schedule.

Reuse and recycling solutions

The only solution to improve recycling and reuse of construction and demolition waste that was recognised as being effective by all the key players was the use of SWMPs. These plans improve recycling and reuse as they require each sub-contractor and main contractor to identify their expected waste streams. This then enables the planning of what can be recycled and when. It also allows for the planning of reuse of materials. Furthermore if the SWMP is integrated in at the design stage it will allow for better evaluation of waste and can allow for greater reuse of waste within the design. In addition Tam (2007) found that if it is integrated at this stage it can help identify areas where waste can be reduced.

CONCLUSION

This research has shown that whilst only just over one third of questionnaire respondents signed up to the commitment, all displayed an awareness of the issues of waste within construction. Landfill space is running out. If the target is not a success then stronger measures will have to be implemented by government. However this should not be the case as there are enough opportunities and solutions that can be utilised to prevent the disposal of waste at landfill. In addition if such methods are adopted cost savings can be made which could be especially significant in these current times where construction companies are making a loss on projects just to keep their cash flowing. Prevention is the best cure and can also provide the most benefits but does require collaboration between the key players in the construction industry. Reuse and recycling is easier to implement and may be the uncomplicated answer to fulfilling the commitment.

ADDRESSING CORRUPTION IN INFRASTRUCTURE PROVISION IN DEVELOPING COUNTRIES

Abiodun Adeyemi Adeniji[1]

[1] *Aspin International Limited, 1, Ligali Ayorinde Street, Victoria Island, Lagos, Nigeria*

ABSRACT

Financial leakages in infrastructure services which includes kickbacks, bribery, fraud and embezzlement is damaging. It damages developed and developing countries, hence, resulting in projects which are unnecessary, unreliable, unwanted, unscrupulous, abandoned, and over-priced. This leads to poverty, loss of life, economic damage and underdevelopment (Transparency International 2011). Corruption erodes the benefits of infrastructure in developing nations. Over $340 billion was estimated as the amount loss to corruption in construction industry (America Society of Civil Engineers 2004) worldwide every year. This undermines the provision of infrastructure facilities (Sohail and Cavill 2008) and poses significant threats to developing nations' development. This paper investigates what causes corruption during the construction of infrastructure projects and what can be done to address it in developing nations. Corruption is a major factor that reduces growth and worsens poverty in developing nations (Wren-Lewis 2004), and it undermines it rate of development. With improvement in monitoring, transparency and accountability before (pre contract) and during construction works, the level of corruption can be reduced therefore, reducing the negative impact of corruption of general populace.

Keywords: construction, corruption, development, infrastructure, leakages.

INTRODUCTION

Construction industry all over the World has a reputation for corruption, misappropriation of funds, bribery, and money laundering. According to Transparency International (2011) corruption on construction projects damages the developed and developing world, resulting in projects which are needless, defective, and over-priced. This leads to poverty, loss of life and economic damage and underdevelopments, especially in developing nations. It also damages companies, resulting in tendering ambiguity, wasted tender expenses, increased project costs, economic damage, reduced project opportunities / extortion and blackmail criminal prosecutions, fines, blacklisting and reputational risk.

Development of a nation is largely depending on the provision of infrastructure services for the public. A well procured and maintained infrastructure makes the development of a nation to be rapid both economically and socially. However, it has been observed in the World over that infrastructure services (water, electricity, school,

[1] adenijiyemi@yahoo.com

 ISBN: 978-1-84219-840-7 .

health, transport, solid waste, access road and paving, community building) provision are not enough and not well maintained, especially in developing nations.
Corruption is a major factor that reduces growth and worsens poverty in developing nations (Wren-Lewis 2010). Foreign investors are unwilling to invest in the resources and technology that are needed in developing countries to improve their domestic macroeconomic performance because of high levels of corruption (Mbaku 2007).

America Society of Civil Engineers (2005) stated that the cost of corruption in infrastructure provision is not only of high economic cost, but also a high human cost. The cost of corruption cannot be measured, since payment of bribes in most cases is not open nor recorded publicly (Transparency International 2010). Whilst Dreher and Herzfeld (2005) stated that over US $1 trillion is paid as bribes every year, out of which corruption in construction accounted for almost half (ASCE 2010), which shows that 50% of infrastructure allocations go to corruption (Anon, 2011) alone.

Research aim and objectives
This research aims to understand and research into how financial leakages in infrastructure provision can be eradicated, hence improving the quality and quantity of infrastructure services in developing countries (Nigeria).
The following objectives have been identified in pursuant to the aims of this research:

- Identify the factors that contribute to the lack of monitoring, accountability and transparency during the implementation and development of infrastructure projects or services in developing nations.
- Determine the main causes of corruption or why people are corrupt when providing infrastructure services.
- Establish the best way corruption can be reduced or eliminated during the construction processes.

Justification of the research
Provision of infrastructure is a major milestone in the development of a nation while developing countries still lag behind in infrastructure provision in the world over.

Developing nations have no good infrastructure provisions to show for their development due to corruption or financial leakages that eroded it implementation hence, the need to delve into the causes to assist in proffering solutions

Research methodology
Both Quantitative and Qualitative methods were adopted for this research due to the sensitivity and in order to be able to address the said objectives. Quantitative data was gathered through well-constructed questionnaire of which 81 was received and analysed out of 171 sent out through different means (on-line, postage, and hand-to-hand). Of all these, hand-to-hand is most successful due to lack of infrastructure (Electricity, internet) provision. On the other hand, qualitative data was gathered through interviewing 2 Quantity Surveyors, 3 Civil Engineers, 2 Architects and 2 Construction Managers with various years of experience in Construction and Infrastructure provision projects.

The evidence gathered from the qualitative (interviews) was analysis based on the similar responses from the nine interviewees. Whereas, quantitative data was analysis by finding the relative importance index (RII) because of the nature (likert) of the questions and also using mathematical (graph) method.

 ISBN: 978-1-84219-840-7 .

INFRASTRUCTURE

Infrastructure has generally been recognised to be a main determinant of growth and productivity convergence in the entire world (Briceno-Garmendia, et al 2007). It is refers to by EIC (2006) as a necessary prerequisite for economic growth and good efficient use of a nation's resources. Provision of infrastructure services has direct impact on the investment, it creates employment opportunities, therefore, improving the living conditions of the affected population and reducing poverty.

An infrastructure provision apart from contributing to economic growth it is also a very important input to human development (Foster and Bricenco-Garmendia 2010), which in turn reduce poverty and inequality in any society. Certain infrastructures are investments tools that will help reduce poverty. Provision of infrastructure will allow low-income earners to devote more time to earn more income rather than spending such time on water collection or trekking long distance (Fox, 1994). Non availability of infrastructure like rail, power (electricity), water makes people spend more while they earn less.

CORRUPTION

Corruption is a major factor that reduces growth and worsens poverty in developing nations (Wren-Lewis, 2010). A huge loss is being incurred through corruption in infrastructure. About 5 to more than 20 per cent of the total cost of infrastructure services are lost to bribe payments, which is just part of economic damage from corruption all over world (Mumssen and Kenny, 2007). Kenny (2006) stated that stolen of electricity by customers in collusion with staffs accounted for as much as 20 to 30 per cent. Furthermore, the stolen of materials during construction reduced the benefits of the road to end users by an estimated $3.41, since building or construction work with insufficient material reduces its life span (Mumssen and Kenny, 2007).

Corruption in different stages of infrastructure delivery

Corruption is a very broad term which takes many forms and can be found in all stages of infrastructure project (see Table 1).

TABLE 1: Corruption in various stages of infrastructure delivery

Stage of service delivery	Examples
Project selection	• Corruption can negatively affect the selection of projects. For example, corruption can divert resources away from social sectors and toward major infrastructure projects. • Corruption may also encourage the selection of uneconomical projects because of opportunities for financial kickbacks and political patronage.
Planning stages	• Project used as vote winners/opportunities for personal gain not on basis of priority/availability of financial resources. • Planning in favour of high value infrastructure (white elephant projects) and against the interest of the poor. • Project requirements may be overstated or tailored to fit one specific bidder. • Over-investment in capital goods at the expense of GDP growth.
Inspection stages	• Weak oversight and supervision mechanisms have been created that would prevent detection of fraud and corruption. • Kick-backs can be given to persuade inspectors to turn a blind eye to slow implementation of projects, unfulfilled contract requirements, and

	other instances of malpractice.
Design	• Corrupt selection of consultants for feasibility studies, preparation of specifications/bid documents. • Over designed and overpriced projects to increase potential corrupt earnings during implementation. • Bribe for favourable environmental impact assessment/planning proposal/approval. • Project design has been manipulated to benefit particular suppliers, consultants, contractors, and other private parties. • The timing of the project has been altered to suit vested interests.
Bid and contract signing stage	• Political parties levy large rents on international businesses in return for government contracts. • Officials take percentages on government contracts. • Officials receive excessive "hospitality" from government contractors and benefits in kind. • Kickbacks for construction and supply contracts. • Lack of competitive/inequitable contract practices. • Inappropriate bidding procedures; excessively short bidding time or insufficient or inadequate advertising of tender. • Corrupt practice on the part of bidders (e.g. unjustified complaints, misleading bids). • Collusion among firms or between public officials and bidders. • Bid rigging in construction contracts can be facilitated by corrupt project managers and quantity surveyors, (people who are supposed to be policing contracts and making sure the clients get value for money) • Compensation payments included in the tender price: when two firms collude, and one prices self out of one of the job and receives a compensation payment from the other as a reward. • Cash-plus contracts enable unscrupulous firms to inflate the value of the contract • The entrance fee, for example a public authority agrees to give a private company the contract, provided that the company pays a fee. The company that pays the highest entrance fee wins the concession.
Construction	• Cutting corners, ignoring rules, by passing procedures • Payment for equipment, materials or services which were not supplied. • The provision of equipment or goods of lower then specified quality (typical examples include lesser cement or steel reinforcements). • Concealing substandard work. • Bribe the relevant official to certify that the work was done according to specification. • Unjustified complaints from contractors as a way to obtain unjustified contract price increases. • Duplication of payments, alteration of invoices, lack of supporting records, ineligible payments, over billing, misuse of funds (i.e. for purposes other than those aligned to project needs), misappropriation of discounts from suppliers/contractors, unauthorised payments etc. • Unauthorized use of project property. • Theft of materials, equipment or services. • Entrepreneurs and brokers that exist as 'fixers' facilitating relations between government and business players and negotiate the various administrative and legal steps.
Service delivery	• Ghost/absent workers. • Siphoning off supplies to market.

Maintenance and management stages	• Favouritism in hiring/promotions • Use of contacts/money to get better/faster service or to prevent delays. • Elite capture of infrastructure services. • Corruption in procurement of equipment and spare parts. • Withholding needed approval/signatures of gifts/favours. • Corruption increases costs meaning lack of resources for O&M. • Bribes to win O&M contracts/ personnel appointments. • Lower standard of construction creates need for expensive repair and maintenance.

Source: Sohail and Cavill, (2008), and Cavill and Sohail, (2007)

Factors that affect the quality of work during construction processes;
Various factors were attributed as the causal of poor delivery of construction work during execution processes. With regards to the respondent shown in figure 1 below, where '1' represent the most influential and '6' the least influential factor, it indicated that lack of proper monitoring and supervision is the *most influential* factor that affects the quality of work in construction works followed by substandard materials.

Factors responsible for lack of monitoring, accountability and transparency on construction projects;
After careful consideration average rating (see figure 2) it has been observed that 'selfish interest' is the most important factor with average rating of 1.35, followed by 'greediness' with the rating 1.46. Low or insufficient salary and uncared attitude were both rated 3rd and 4th with 1.86 and 1.95 respectively. Average rating calculation also revealed that 'lack of ability / insufficient of judiciary in punishing corrupt officials' and 'lack of awareness' were rated into 5th and 6th position with 2.22 and 2.27.

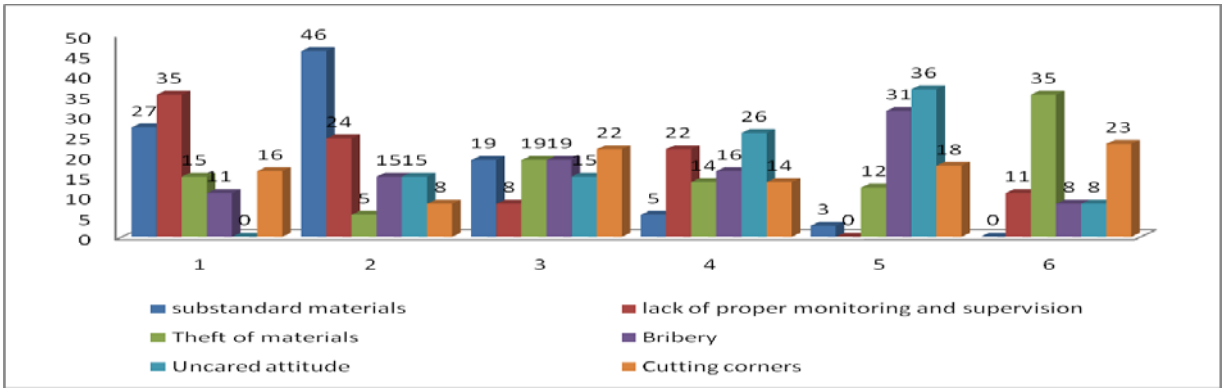

Figure 1: Factors that influence the quality of construction projects.

Proper accountability and what can be achieved to improve infrastructure provision;
From the survey conducted, table 3 shows that 92% of the respondents believed that if accountability is properly implemented, it will help improve the quality and quantity of infrastructure provision in developing countries (Nigeria) (49% indicated that is going to be very effective and 43% indicated that it can be effective). While negligible 3% indicated that is impossible in Nigeria system and the remaining 5% remained neutral.

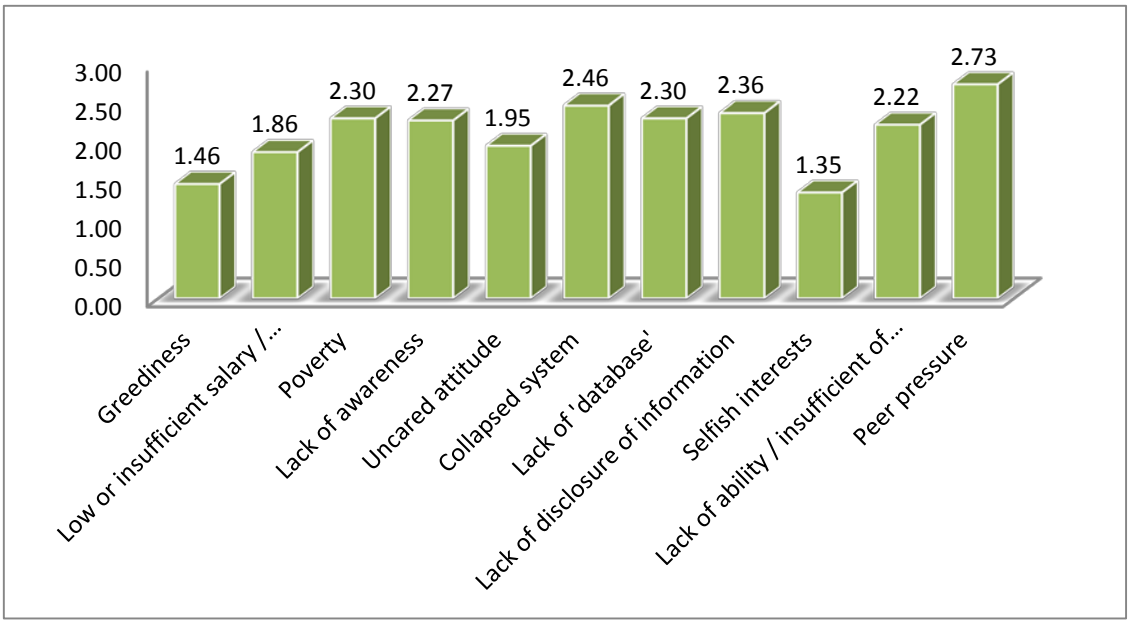

Figure 2: Causal of corruption during construction execution processes

Table 2: Effect of proper accountability

	%
Very effective	49
Effective	43
Neutral	5
Not effective	0
Not very effective	0
Impossible to predict	3

Monitoring

Questionnaires survey results show proper monitoring during construction processes will be *very effective* and *effective* with total 92% of respondents supporting the motion, while the remaining 8% went neutral.

Table 3: Proper monitoring during construction processes

	%
Very effective	70
Effective	22
Neutral	8
Not effective	0
Not very effective	0
Impossible to predict	0

Causes of corruption

From the interview conducted, it was gathered that the main causes of corruption is pressure from the government for not providing necessary infrastructures, starting from water, good road, electricity, good education, hospitals. These make people to be under pressure of looking for money to cater for *complex* needs.

Other similar causes identified are; government lack focus on what to provide, poor wages or salary, three of the respondents specifically made mentioned of lack of national identification system (cards) which made it possible for everyone in the country to be anonymous.

Lack of accountability, monitoring and transparency.
Accountability, monitoring and transparency has identified by Sohail and Cavil 2008, provide effectiveness of public officials or private organisation to perform to their maximum capacity, which resulted in providing value for money, instilling confidence in the government and being responsible to the communities as a whole or the whole country in general.
From the evidence gathered, it can be seen that proper monitoring by given relevant instruction, quality control and thorough supervision during construction processes will help improve the quality of work, reduce the amount of wastage and increase people's confidence in the government. Accountability and transparency of the officials involved in the construction processes are other important factors that were mentioned. If the supervising teams are accountable for their various actions, they will be serious and make sure that proper things are done.

CONCLUSION AND RECOMMENDATION

Some of the factors that ginger corruption during construction execution processes were identified and how it can be reduced or eliminated were obtained from the data. The following conclusion can be drawn from this research results:

- From the results, it can be seen that the factors responsible for lack of monitoring during construction project execution included selfish interest as believed by majority of the respondents. It was feasible that if proper monitoring, accountability and transparency can be put in place by certain means, the level of corruption will be reduced.
- Corruption is the main reason why developing countries are far behind in infrastructure provision despite the huge amount of money spent. Hence there is need to for the involvement of other stakeholders (users) during the planning activities, checking and removing unnecessary expenses before and during execution processes (value engineering), engagement of qualified contractors directly for project execution rather than encouraging nepotism, monitoring by qualified professionals as well as task forces, execution of relevant infrastructure projects rather than money generated infrastructure projects.

Corruption will be reduced or eliminated in construction projects if all stakeholders (inclusion of multi stakeholders in project execution) join hands in the development and implementation of effective anti-corruption programme which tackle both supply and demand sides of corruption.

CASE STUDY: CONSTRUCTION COMPANIES AND THE SUCCESS OF THE RECONSTRUCTION PROCESS IN KOREA

ABSTRACT

This study investigates the roles of construction companies during the reconstruction process of apartment buildings in Korea. The main actors in the reconstruction process include: the reconstruction association; the construction company; the buyers (association members and new buyers); and the local authority. There are two types of project participation for construction companies in the reconstruction process: the traditional contractor arrangement; and the turnkey base (design/build) contract. The results of the case study show that construction companies are critical to the success of reconstruction projects because of their performance guarantees for project financing and their brand names for sales of apartment units.

Keywords: apartment building, brand name, construction company, Korea, project finance, reconstruction

I.NTRODUCTION

From the 1970's, the Korean government's promotion of large-scale multiple family housing construction project was driven in response to ongoing national housing shortages. In the 1990's alone, the Korean government promoted two million housing units construction projects domestically. Since the 1990's, the multiple family housing buildings (mainly apartment buildings) built in the 1970's and 1980's had become

[1] j.kim@unsw.edu.au

[2] michaelb@fbe.insw.edu.au

[3] hyunslee@snu.ac.kr

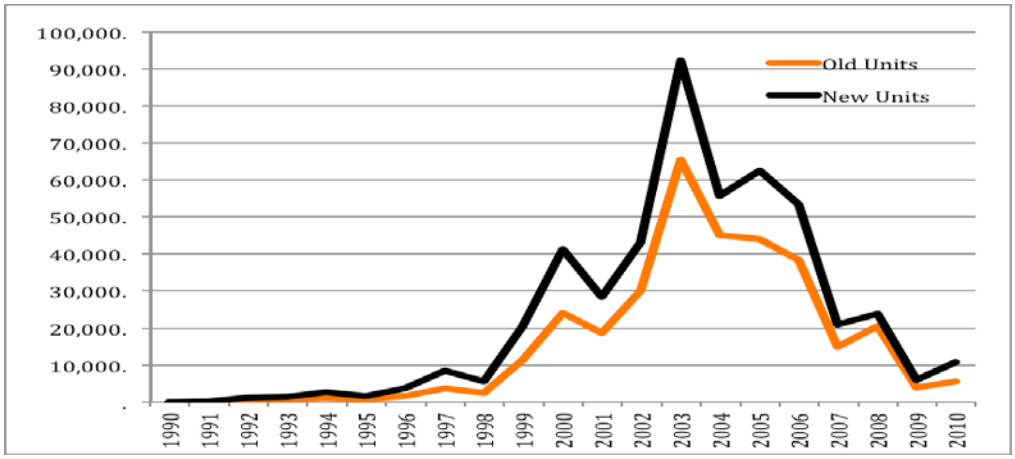
[4] mspark@snu.ac.kr

appreciably deteriorated. Consequently, demand for urban regeneration to improve the quality of old apartment buildings has increased. The enactment of the *Urban and Housing Environment Regeneration Act 2002* provided a turning point for urban consolidation and housing redevelopment/reconstruction projects in Korea. There were significant increases in the number of reconstructed housing units after 2002. Figure 1 shows the numbers of old and new housing units in reconstruction projects from 1990 to 2010 in Korea.

The main purpose of the housing redevelopment project is to remove run-down houses and to take steps to prevent the areas from further deterioration. The housing reconstruction project was also put in place to remove deteriorated apartment buildings and develop new apartment buildings. As the results, new high-rise apartment buildings were generally developed in those areas.

The aim of this study is to investigate the roles of construction companies during the reconstruction process of apartment buildings in Korea.

FIGURE 1: Number of Old and New Housing Units in Reconstruction Projects (Development Application approved)



Source: Ministry of Land, Transport and Marine Affairs (MLTM), Korea

RECONSTRUCTION PROCESS

The reconstruction process must be undertaken in accordance with the procedures in the existing laws. Existing owners of old apartment buildings voluntarily form a reconstruction association, then demolish deteriorated existing apartment buildings and construct new apartment buildings jointly with construction company on the site where the old buildings were located. The *Urban and Housing Environment Regeneration Act 2002* defines a deteriorated housing building for redevelopment/reconstruction as: (i) a structure that is extremely damaged or partly collapsed whereby the potential for total collapse is high or a potential safety hazard; (ii) a building that is located in very poor

housing environment compared to the neighborhood land use condition; (iii) there is a considerable increase in the expected utility if demolished and redeveloped as compared to undertaking excessive repairs and maintenance costs; and (iv) 20 years have passed since initial construction and needs to be demolished due to poor urban landscape, structural defects by aging and deficient construction.

The Table 1 shows typical procedures of the redevelopment/reconstruction of apartment buildings. A District Office establishes a ten-year 'Urban Housing Regeneration Plan' and reviews it every five years. Based on the Urban Housing Regeneration Plan, a deteriorated site area could be designated as 'Urban Regeneration Zone'. A group of existing land and housing owners within Urban Regeneration Zone can organize a redevelopment promotion committee, while a group of existing owners of old apartment buildings can organize a reconstruction promotion committee. The aim of the committees is to persuade existing owners to consent to the redevelopment/reconstruction process based on the preliminary cost-benefit analysis or feasibility analysis. The reconstruction promotion committee must submit a 'Building Safety Inspection Application' to the District Office. The agencies assigned by the District Office thoroughly inspect any physical deterioration, defects and damage to structures and submits inspection reports to the District Office.

TABLE 1: Redevelopment/ Reconstruction Process

	Steps	**Details**
1	Urban/ Housing Regeneration Plan	Prepared and approved by Metropolitan City Mayor or approved by Regional Governor (prepared by City Mayor)
2	Urban Regeneration Zone	Prepared by District Office and approved by Metropolitan City Mayor. For **redevelopment** project
3	Promotion Committee	Approval with more than half of the existing ownerships
4	Building Safety Inspection	For **reconstruction** project only
5	Establishing of Association	- **Redevelopment:** approval with more than 3/4 of total ownerships and more than 1/2 of land ownerships - **Reconstruction:** approval with more than 3/4 of total ownerships and more that 2/3 ownerships in each building
6	Registration of Association	Approved by District Office Project plan and Development Application
7	Development Application Approval	Approved by District Office
8	Selection of Construction Company	Tender, Presentation by the construction companies, Selected by association general meeting

Existing owners must vote to decide whether they will pursue any reconstruction process. In order for reconstruction to be possible, three-quarters of the existing owners in the complex, and two-thirds of existing owners in each building, must vote in favor of any reconstruction proposal. If the proposal is consented to in the association general meeting, a reconstruction association can be established. A 'Disposal Claim' would be issued to existing owners who do not want to participate in the reconstruction project. If the old apartment buildings pass (negatively) the Building Safety Inspection test, the District Office reviews the appropriateness of reconstruction plan and the association members' qualifications (only the existing owners of housing units can be members) and officially approves the reconstruction association (Lee *et al.* 2005).

The association selects a construction company or companies (if it is a large-scale development), and the association and the construction company submit a development application to the District Office, and obtains an approval for demolition and construction from the District Office. The association and the construction company finalize the 'Ownership Control and Transfer Scheme' that the values (the 'Credit Portion') of existing association members' old housing units are decided. During the construction period, existing owners must move out from the complex. Most of them find their temporary housing in the neighborhood community as rental tenants. The construction company fully or partly subsidizes any rental costs based on the size of old housing unit. If there are any additional units available in new housing buildings other than existing owners as the result of increased floor space ratio (FSR), those additional units could be sold. The income generated from the sales would normally be the main source of payments to the construction company. After the construction is completed, existing owners and new owners move into the new apartments, at which time the reconstruction association is dissolved.

A reconstruction association can determine the number of new housing units and their sizes if it satisfies certain regulated floor space ratio (FSR) constraints, but each existing owner is allowed to obtain only one new housing unit after reconstruction. However, the number of housing units developed in a complex through reconstruction is normally greater than the existing number of units since the new project has a higher FSR than existing buildings (e.g., high rise apartment buildings with more and larger size units).

This high rise and high density building is a result of combinations of an increased FSR by the Government, the profit-maximizing behavior of the existing units owners, and generally sufficient demand for housing units in Korea.
Through the reconstruction process, it is found that the main actors in the reconstruction process are: (i) the reconstruction association, (ii) the construction company, (iii) the buyers (association members and new buyers); and (iv) the local authority.

SELECTION OF CONSTRUCTION COMPANY

The selection of a construction company is the most important step for a successful reconstruction project. The construction company not only provides the construction services based on the contract, but also acts as a developer and a lender for the project. The construction company and the reconstruction association are working as partners in the reconstruction project. Whilst the construction company is virtually always a strong organization in terms of knowledge and experience, the reconstruction association is likely to be a relative weak organization. For this reason, the construction company normally manages the reconstruction project.

In the early stage of the reconstruction process, the reconstruction association only has the old run-down apartment buildings as a financial asset. However, there will be some revenues from sales of additional new units and retail areas, which is likely to be the main source of funds to pay to the construction company. The construction company is not only undertaking the construction works, but also supports the operational expenses of the association.

There are two types of contract between the association and the construction company depending on how the parties share the development profits. The contract types include: (i) traditional contractor arrangement; and (ii) turnkey base (design/build) contract. See Table 2 below.

TABLE 2: Contract Methods with Construction Company

	Traditional Contract	**Turnkey Base Contract**
Definition	Total contract amounts for construction works is fixed when the contract is made. (Traditional contract method)	The contractor is responsible for all necessary costs for the project. The Credit Portion of the existing owners is fixed when the contract is made.
Scope of work	- Association: responsible for indirect construction costs, other costs, fees, and taxes - Construction company: responsible for direct construction costs	- Association: responsible for members' taxes and fees - Construction company: responsible for all project costs including construction costs
Escalation	Escalation possible based on	No escalation and change possible

and change	inflation Change possible based on revision of scope and design	after contract
Members' credit portion	Members' Credit Portion can be changed according to the project revision.	As the Credit Portion is fixed at the contract, there is no change after.
Project closing	Development profit or loss belongs to the association (100%)	Development profit less fixed members' Credit Portion and additional construction costs to the construction company

Source: Ministry of Construction and Transportation (2000) Reconstruction Process Manual

In general, the traditional contract arrangement has been the dominant contract method for reconstruction projects. However, since 1993, many reconstruction projects were commenced under Government regulation and so the turnkey (design and build) contract has been the preferred contract arrangement. However, since the Asian Financial Crisis in 1998, the construction companies seem to have preferred the traditional contract method.

The factors considered by the reconstruction association in selecting a construction are (a) the brand power of the company; (b) the debt ratio of the company; (c) total contact amounts of the company in previous year; and (d) the bidding price for the project (Kim 2009). It appears that the characteristics of the construction company, itself, are more important to the reconstruction association than the project tender price in selecting a construction company.

The first priority factor is brand power of apartment name from the construction company. In 1998 the brand name of an apartment building was introduce in Korean housing market (Shin 2009). Since then, the brand naming became very popular in apartment buildings. A housing buyer considers the trustful brand name as one of the most important factors in decision-making process (Ji 2005). As the location of reconstruction project is fixed, the transportation and surrounding environment cannot be changed, which are important factors in decision-making of purchasing an apartment unit. Hence, the association members put the brand power of the construction company as the most important factor to select a construction company, which attract high demands for public sales, and increase the values of their units at the disposal stage.

The debt ratio and the size of the construction company are important because of its key role in the real estate development project finance system in Korea. The construction company ought to submit a completion guarantee in which it promises to timely finish the object buildings by the completion date in the contract. Moreover, the construction company must serve a joint liability on guarantee with the association (borrower). Charging construction company with heavy burdens of Cash Deficit Support (CDS), completion guarantee and debt obligation, a lender can deal a risky credit loan for the

 ISBN: 978-1-84219-840-7 .

borrower (association), which has no hard asset security and is uncertain about the sufficiency of repayment resource in maturity (Kim & Sakong, 2009).

CASE STUDY

'Project A' was a reconstruction project in the southern part of Seoul, Korea. There were 2,400 housing units in old five-storey buildings before reconstruction. The new development included 3,410 housing units in 44 new apartment buildings (29 storey with two basement levels), and other welfare facilities. The Development Application was approved in October 2004, and the Ownership Control and Transfer Scheme was approved in February 2005. The construction was commenced in April 2006 and was completed in March 2009. See Table 3 below.

As the FSR was increased from 80% to 269%, the old 2,400 housing units with average 64.7 m^2 per unit were demolished and 3,140 housing units, with average 166.9 m^2 per unit, were developed. The association members purchased 2,377 units, and among the remaining 1,033 units, 593 units were sold to the public with 440 units assigned as public rental housing. The Credit Portion of the existing owners was finalizes at USD 1,239 million in the Ownership Control and Transfer Scheme. Total costs of the project were estimated as USD 822 million including direct construction cost of USD 504 million.

TABLE 3: Summary of the Project A

	Description
Developer	BJ3 Reconstruction Association
Construction	OO Construction Co Ltd
Location	Seocho-gu, Seoul Korea
Zone	General Residential (type 1), Apartment Zone
Site area	194,118 m^2
Old Buildings	FSR: 80% Total building area (above ground): 155,295 m^2 2,400 housing units
New Buildings	FSR: 269% Total building area (above ground): 524,086 m^2 44 apartment buildings (2 basement levels and 29 storey) 3,140 housing units and other welfare facilities
Credit Portion	194,118 m^2 x \$6,385 per m^2 = U\$1,239.4 million
Costs	Total costs: U\$822 million Construction: \$504 million Design, financing, and others: \$318 million
Revenue	Total revenue: U\$ 877.5 million Members' contribution: \$372.6 million General public sales: \$425.9 million Rental housing compensation: \$79 million (value: \$226.5 mil)

Development Profit	U$1,345.1 million ($560,500 per unit) (Total value – Credit Portion – Total costs) Total value: $3,406.5 million (524,086 m^2 x $6, 500 per m^2)

Source: Jung (2006), Kim (2006) (U$1 = KRW1,164)

The association members' contribution for purchasing was estimated as USD 372.6 million, and the revenue incomes from general public sales were initially estimated as USD $652.4 million. However, as the Government introduced the compulsory rental housing inclusion for reconstruction project in March 2006, 10% of the additional building areas were developed as public rental housing – the regulation is 25% of additional building areas. As the Development Approval of the project was approved by March 2006, the project was allowed to supply 10% of additional building areas as rental housing units. The rental housing compensation from the Government was USD 79 million instead of the worth USD 226.5 million. The total incomes of the project were estimated as USD 877.5 million, which provided USD 55.5 million as profit for the development.

The initial development profit was estimated as USD 1,345 million – an average of USD 560,400 per existing owner. The introduction of compulsory rental housing created a significant setback in development profit. The value of new housing unit was initially estimated as USD 6,500 per m^2. However, the new housing value was estimated as USD 9,100 per m^2 when the project was completed in 2009.

OO Construction Co Ltd is a part of a large conglomerate and viewed as having a top brand name and sound credit rating (A2). It could provide not only superior construction service for the project, but also a necessary guarantee for project finance. As the contract method was a turnkey base (design/build), the construction company would be responsible most of costs and profits from the project variation once the Credit Portions of the association members were fixed. The construction company provided a completion guarantee and a joint liability with the association to the lender for project finance.

As this reconstruction project was located at one of the best residential areas in Seoul, and is close to transportation facilities, there was expected to be very high demand for public sales. The reconstruction project was approved the Ownership Control and Transfer Scheme on February 2005, one year before the Government's Reconstruction Control Plan on March 2006, which setup the high bars for new reconstruction projects (Jung 2006). Hence, this project is very attractive to the existing owners as well as general public. However, the lender requested the construction company to serve the joint liability on guarantee with the association, notwithstanding that the construction company (with a sound credit rating) provided the completion guarantee.

CONCLUSION

There are four main actors in reconstruction project: (i) the reconstruction association; (ii) the construction company; (iii) the buyers (association members and new buyers); and (iv) the local authority. To select a construction company, a reconstruction association considers (in descending importance): (i) the brand power of the company; (ii) the debt ratio of the company; (iii) size of the company; and (iv) bidding price for the project construction to be the key factors. The brand power of the construction company is the most important factor for sales of reconstructed apartment units because the location of the project cannot be changed. The debt ratio and size of the construction company are also very important for the project success because a lender normally requires the construction company to provide a completion guarantee and a joint liability on guarantee with the association (borrower) even though the reconstruction project is seen to be very profitable. Hence, the selection of a construction company is the critical step for the successful reconstruction process in Korea.

ABSTRACT

Forecasting the supply of commercial office buildings is critical for the economic development. Using the data from Hong Kong, the major factors influencing the supply of commercial office buildings such as gross domestic product, property prices, vacancy rates, interest rate are examined. Unlike the investment in financial assets, commercial office building developments are characterized by a time lag from the decision to build until their completion. The lead-lag structure of these major factors in determining the supply of office buildings is identified. Using the technique of polynomial distributed lag, the lead-lag model is simulated, and provides a reliable forecast on the supply of office buildings. Considering the prevailing shortage of commercial office buildings as result of economic growth in Asia, the forecasts derived from the model are deemed to be useful for economists and property analysts to facilitate their investment decision-making in the future.

Keywords: economic development, forecast, distributed lag model, investment decisions, office building,

INTRODUCTION

The accuracy of forecasting techniques to predict the supply of the office buildings (in terms of meter squares) has long been critical for the development of an economy. Most construction industries around the world are portrayed as high unstable activities and even being volatile than other industries (Rosenfeld and Warazawski, 1993; Goh, 2000; Song and Liu, 2007; Sing *et al*, 2012). Its cyclical nature in output has posed many problems such as the suppression on economic development. In addressing the need to accurately predict the completion of buildings; several models have been propagated in respect to different types of property construction (Nicholson and Tebbutt, 1979, Puri and Lierop, 1998; Kling and McCue, 1991; Giussani andTsolacos, 1994; Tsolacos, 1998). However, there have been few empirical studies on modeling

[1] michael.sing@curtin.edu.au
[2] p.love@curtin.edu.au
[3] xiangyu.wang@curtin.edu.au
[4] Jim_Smith@bond.edu.au

the supply of office buildings using the economic indicators as well as a lead-lag relationship between them. Against this contextual backdrop, this paper develops the distributed lag model to provide an accurate prediction on the construction output of office buildings in Hong Kong.

Forecasting is a process to portray the uncertain future and plays an important role in the process of making a rational decision regarding the effective utilization of the various resources. Makridakis (1983) and Makridakis*et al.* (2009) suggested that there is always a lag time between the impending event and occurrence of that event. To determine when an event will occur or a need will arise; forecasting can make a statement about the future on the presumptions that the future will be like the past. However, the forecasting process always involved complex procedures and consideration on different factors. In order to provide accurate forecasting toward the future, there are several techniques that have been developed and which can be mainly divided into three broad categories. They are (a) Multiple regression model; (b) Granger and Causality Analysis and (c) Vector Autoregression model (VAR).

(a) Multiple regression modeling

Multiple regression modeling is applied to establish the causal-effect relationship between one dependent variables in terms of one or more other independent variables through the examination of the past data series. The forecast value of independent variable would then be projected through this relationship. The general form of the multiple regression modeling is shown in Eq.[1].

$$y_i = b_o + b_1 x_{1i} + b_2 x_{2i} + ... + b_k x_{ki} + \varepsilon_i \quad \text{.....Eq.[1]}$$

where:

y_i = ith observation of the dependent variable, y

x_{ji} = ith observation of the j th independent variable

b_o = intercept term with Y-axis

b_j = regression coefficient for each of the independent variables (i.e. $j=1,2,3...$)

ε_i = the residual (or error term) for the ith observation

Several authors have applied this technique in forecasting construction variables such as price, demand and construction output. Puri and Lierop (1988) first applied this technique in examining the housing starts in U.S. and a number of regression equations are integrated into economical model. The key variables examined in their model are related to mortgage commitment, flow of deposits and interest rate, etc. In addition, Tang *et al.* (1990) have applied the regression model in predicting the construction demand in Thailand and Singapore construction industry respectively.

(b) Granger Causality Relations

In Granger Causality relations, it is assumed that the relevant universe of information consists only of time series, $X_1(t)$ and $X_2(t)$, X_1 is said to Granger-cause X_2 if the

lagged values of X_1 can provide better prediction on the future values of X_2 than using only the lagged values of X_2.

$$X_2(t) = \sum a_j X_2(t-j) + \sum b_j X_1(t-j) + \alpha \quad \text{.....Eq.[2]}$$

where:

X_1 = stationary variables to explain the variable X_2

X_2 = variables to be explained

a_j, b_j, α = constant

and test the hypothesis:

$$H_0 : b_j = 0, j = 1,..., j \quad \text{.....Eq.[3]}$$

If the t-statistics is statistically significant, it can be concluded that H_0 should be rejected and X_1 Granger-causes X_2.

Meanwhile, Tse and Ganesan (1997) applied the same theory in identifying the relationship of construction flow and GDP in Hong Kong. Lean (2001) also developed another model based on Granger Causality Test in identifying the relationship of the construction flow and other outputs of other sectors within the Singapore economy.

(c) Vector Autoregression (VAR) model

The VAR model is extension of the Granger-Causality relation, which contains more than one variable under study. The model is designed to forecast the value of variable based on its own lags and the lags of all the other variables in the model.The VAR model has been used to model new work orders for industrial buildings and retail development (Kling and McCue, 1991; Tsolacos, 1998). Kling and McCue (1991) applied a VAR model to examine the relationship between the industrial construction and the macro-economy. Similarly, Tsolacos (1998) developed a VAR model based on changes in real consumer expenditure and real retail returns.

DATA COLLECTION

The data used in this study includes the available quarterly time series for completion of office building (in term of squared meter), gross domestic product, property price index and vacancy rate of office buildings from January (Q1) 1993 to December (Q4) 2010. Those statistics are extracted from the government publications such as the *Property Review* issued by Rate and Valuation Department, economic statistics from Census and Statistics Department of Hong Kong government. To prevent any random short-term fluctuations that may have been taken into account, a centered four-quarter moving averages technique would be employed for estimating the trend of the raw

data in the presence of quarterly seasonality. Eq.[4]is applied for estimating the trend of the raw data in the presence of quarterly seasonality.

$$\widehat{y}_i = \frac{y_{i+2} \cdot 1/2 + y_{i+1} + y_i + y_{i-1} + y_{i-2} \cdot 1/2}{4} \quad \text{.....Eq.[4]}$$

MODELING ON THE SUPPLY OF OFFICE BUILDINGS

To forecast the supply of office buildings (in terms of meter squares), a polynomial distributed lag model is developed using EViews 7® for Window 7. The proposed model is distinct from previous studies, as it is utilize a lead-lag structure of economics related, the concept of autoregression. To identify the influence of those selected variables, the Granger-Causality and Graphical comparisons are used to identify their correlation. Based on the nominative literature review, the selected variables are (a) completion of office building in previous years, s_{t-i} (b) Business cycle in terms of gross domestic profit, GDP_{t-i}, (c) vacancy rate, vr_{t-i} and (d) property price index, ppi_{t-i}.

The concept of the Granger-Causality test is applied to determine out the statistical lead-lag relationship between the projected construction output and economics variables. To conduct the Granger-Causality Test, the time-series should be stationary (Zhou, 1996; Studenmund, 2001).A stationary time-series properties are constant over time (i.e constant variance), without trend and no periodic fluctuation. Two methods can be used to determine if a time series data is non-stationary. The simplest method is to visually examine the pattern of the dataset to determine if there is any exponential growth. A more scientific approach however is the application of the Augmented Dickey-Fuller (ADF) test. The null hypothesis for the ADF states a unit root or an underlying process is non-stationary exists. The ADF model is defined as:

$$yt = c + dt + ay_{t-1} + b_1 \Delta y_{t-1} + b_2 \Delta y_{t-2} + \ldots + b_p \Delta y_{t-p} + e(t) \quad \text{.....Eq.[5]}$$

and run a one-sides *t*-test on the hypothesis that $a = 1$

$$H_0 : a = 1$$
$$H_1 : a < 0$$

To illustrate the procedure to determine if a time series is stationary, Figure 1 provides plots of the quarterly supply of office buildings at Hong Kong used in the proposed model. It demonstrates a notable pattern of movement during the 1993 to 2010 period and the likelihood that non-stationary may exist. The non-stationary can be removed by the first differencing variable (Lutkepohl, 1999). In this model, the time series data has been transformed into the rate of change in supply of office buildings for providing stationary properties. The datasets used to formulate the forecast model have demonstrated that they are in stationarity term, which is the basic

requirement for applying the Granger-Causality test. In addition, the results of Granger-Causality test indicates that (a) supply of office building in previous years, s_{t-1}, (b) Gross Domestic Product, GDP_{t-i}, (c) vacancy rate, vr_{t-i} and (d) property price index, ppi_{t-I} are both significantly influence a change in supply of office building.

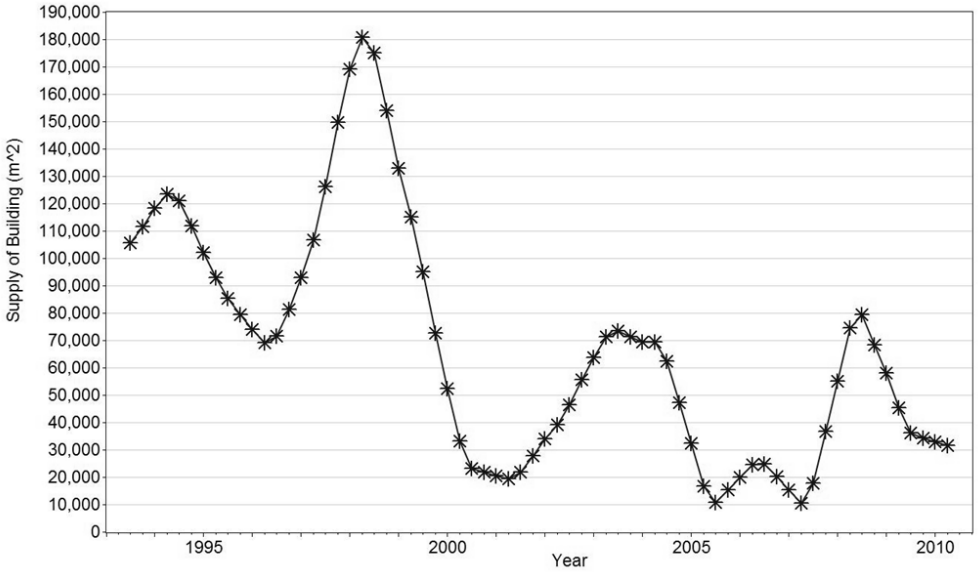

Figure 2 Time plot of quarterly office buildings at Hong Kong, 1993-2010

With the Granger-Causality test, it has to provide statistical evidence on the correlation between a change in supply and selected economic variables. The next step is to apply graphic comparison method for comparing supply of office building with key variables and to identify their lag structure. For example, in Figure 3, it is observed that the curves in the figures demonstrate a correlation between supply of office buildings and business cycle (GDP) and the lags for the period commencing 1993 were 4 to 8 quarters.

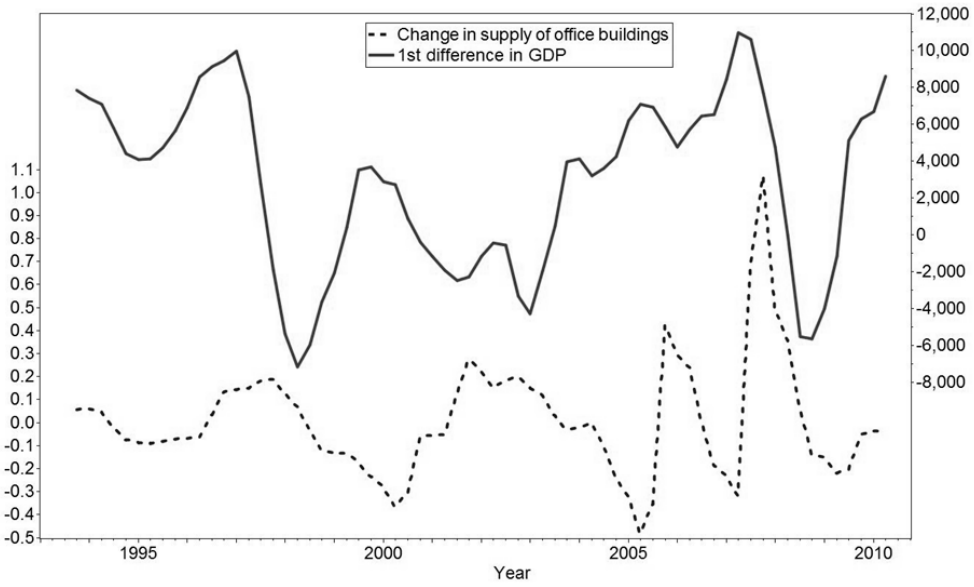

Figure 3 Supply of office buildings verse 1st difference in GDP at Hong Kong

As the lagged structure related for the key economics determinants have been identified in graph method. Using Eview7®, the forecast model for supply of office buildings in the current period is a function of lagged change in (a) business cycle in terms of GDP, (b) property price index, (c) vacancy rate and (d) supply of offices buildings in previous quarters. The equation for this forecasting takes the following form:

$$\Delta fso_t' = \sum_{p=i}^{j} \gamma_{1,p} \cdot \Delta so_{t-p}' + \sum_{p=k}^{l} \gamma_{2,p} \cdot \Delta GDP_{t-p} + \gamma_3 \cdot \Delta PPI_{t-q} + \gamma_4 \cdot vr_{t-r} + \varepsilon_t \quad \text{.....Eq.[6]}$$

Where $\Delta fso_t'$ is the forecast percentage change in supply of office, Δso is change in supply of office building, ΔGDP is change in gross domestic product, ΔPPI is change in property price index, vr is vacancy rate, p, q, r represented the lagged period, $\gamma's$ is constant parameter and ε_t is a random disturbance term.

Under the 95% confidence level of *t*-test, it is found that changes in *GDP* lagged five and six quarters (approx. to 1.5 years), change in supply of office buildings lagged one and two quarters, *change in vacancy rate* lagged six quarters and change in *property price index* lagged eight quarters which exerted the most significant influences on the forecast supply of building with *t+1*. In addition, the *R*-squared of the model is 0.68, which suggests that nearly 70% of the variation in construction output can be explained by this model. The predicted and the actual values are plotted in Figure 4.

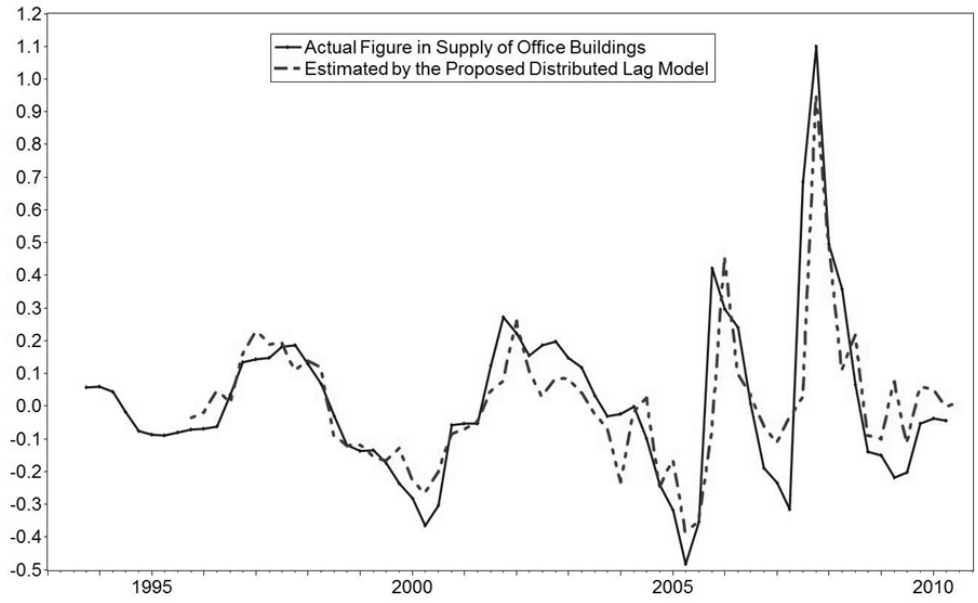

Figure 4 Actual and fitted value by proposed model on forecasting supply change in office buildings at Hong Kong

CONCLUSIONS

The distributed lag model presented in this paper has applied the concept of Granger causality and graphical method to identify the lagged structure between the economic variables and future supply of office building. Unlike the models prorogated in the literature review, four economic related variables were used to forecast supply in terms of squared meter: (a) business cycle in terms of gross domestic profit, (b) property price index, (c) vacancy rate and (d) lead-lag relationship of the office supply in previous quarters. In formulating the model, the quarterly time series were tested using Augmented Dickey-Fuller (ADF) test to ensure they are both stationarities and followed by Granger Causality test to study their relationship with the supply of office buildings. A consistent lag structure was then established through the application of graphic comparison method. With this in mind, a distributed lag model was developed to capture the long-term trend and turning points and R-square of 0.68 was derived. This provide a powerful tools for investors and policy makers on visualizing future supply of office buildings and make any necessary adjustment to their investment and policy strategies.

School of Built Environment, Heriot Watt University, EH14 4AS, Edinburgh UK.

ABSTRACT.

Land is an essential natural resource having numerous competing alternative uses which necessitate definition of potential uses within the ambit of legal framework to enhance compatibility and sustainable development. Basically, the extent of compatibility of land uses on residential real estate in urban areas is a measure of the performance index of the property law and its regulatory structure. Therefore, this paper seeks to uncover the causes of inefficiencies of Nigeria planning laws to prohibit indiscriminate location of graves on residential properties. It explores the Nigerian Urban Regional Planning law with a focus on development control paradigm and its specific ability to prohibit graves on residential properties in Akure. Lastly it examines the effects of the emerging negative externality on property value and sustainable real estate development in the case study. The paper suggests a review of development control laws and re-engineering of its' enforcement strategy with a particular focus on uniform interpretation of planning law on all residential land.

Keywords: grave, land, law, planning, residential.

INTRODUCTION

The provision of three basic necessities of life "food, clothing and shelter" are all subject to availability of land in qualitative and quantitative context. Therefore, given its status as the base of all human activities, it could be inferred that the demand for land ranked the highest of all commodities in the world. The importance of land cut across socio-economic and cultural divide. It is socially seen as a measure of wealth and social status especially in Africa and other developing nations where private land ownership is rife. As an economic good, its investment value is highly attractive as it provides hedge against inflation where many other investments fail during economic recession. Its' ability to maintain economic value in real terms have made it veritable investment asset opportunity. However, potential appreciation in value over time depends on the influence of individuals' land use decisions as well as efficiency of planning laws and development control. Generally, uncontrolled land use often generates negative externalities which culminate in reduction of value. Considering the potential impact of individual landlord's decision, it is globally evident that no government is indifferent to the utilisation of land within its territory. There are huge global concerns to ensure sustainability and prevent diminution in land's potential

ability to meet the needs of future generation. First major attempt at alleviating this concern is traceable to the "city beautiful movement" led by Ebenezer Howard in the 19th century. The ideal of his concept was to develop a residential district which transcends mere shelter surrounded by conflicting land uses. His works and other studies which are consistent with ordering of land uses provided a global take-up point for urban planning and land use control. Contemporary development in urban planning presumes and strongly advocates residential land use development that considers quality human environment and coexist with it. This is to be achieved through laws and development control which seek to ensure development of residential land within the context of socio-economic satisfaction. To a commendable degree, it is seen that this strategy have worked with appreciable result in the western world to prevent conflicting land uses in the cities. Conversely, the situation in the developing world cities is completely at variance. According to a Senior World Bank Official in Bell (1999), the state of land use in Africa suggests that the continent is at the brink of ecological collapse. With this report, the risk factor to real estate investment (land and residential properties) is on the increase in Nigeria and other developing nations bedevilled by conflicting land use. In specific terms, a particular problem of return and rental value on private residential properties in Nigeria is the threat from the escalating number of graves on residential properties. This can be seen as a structural problem of the land market which could be curtailed by efficient planning laws to prevent; reduction in property value, high vacancy rate, high illiquidity of an illiquid asset and stigmatisation. Therefore, the need to salvage residential land becomes ecologically imperative to maintain high level of housing ideal and aesthetically pleasing residential land. This is further strengthened by socio-cultural complexities and religion inclination in a socially diverse human society where cremation and other methods of disposing corpse are forbidden. Consequently, this study critically appraises Nigerian urban planning and development control law with a view to assessing its efficacy toward prohibiting graves on residential properties. The paper is structured into six different sections. Section two examines the use of residential land for grave as well as ownership of cemeteries in the study area. The third section reviews the position planning law concerning location of graves on residential properties. Also, it provides some commentaries on land market and its regulatory framework. The next section gives brief information on the study area and the research methodology. Section five offers discussion on the inefficiencies of planning law. The last section discusses the summary of argument and recommendations.

Land Use for Graves on Residential Property's Land in Nigeria

The growing numbers of graves on streets in many Nigerian cities pose great challenge to their future sustainability. The character of most streets are changing, it is now common to find slogans like; "Rest in Peace (R.I.P), Adieu Papa, the Soul of the Faithful Rest Here" and others on residential properties. After burial services, a statement like interment follows immediately in the deceased residence is common. Also, Medical experts discovered that the recent outbreak of Lasa fever epidemic in Ose Local Government Area and other urban centres established a nexus with graves in residential real estate. The chief vector of this disease 'Rat' burrows into graves of infected corpses and comes out to spread the malady by feeding on domestic foodstuffs.

Presently, cemeteries land is mainly held by established churches, mosques and the

local governments. Accessibility to churches' graveyards is mainly by membership status and the majority of them are filled up. There are also few privately owned cemeteries in some cities like Lagos and Ibadan. However, they are accessible to the rich who can afford the price. Government cemeteries are usually very large but unkempt and not secured. There is evidence of exhumation and mutilated bodies possibly for ritual purposes, perhaps one of the reasons for their low usage.

Observation reveals that graves are a common sight on streets; however the phenomenon does not extend to residential properties on public residential estate (government residential area). This situation leaves the city to a paradoxical correlation of two cities in one; where a part of the city shows marked evidence of development control while the other part is perceived to be developing in a separate uncontrolled land market. The government residential area "an offshoot of the formal land market" is seen as a market for the elite. Private residential areas are products of informal land market. They are seen as home for the low income earners and the commoners. The informal land market is largely unregulated and remains the surest means of accessing land; hence the high level of vulnerability of its use for graves. Observation from neighbouring countries such as Ghana, Togo, Congo, Senegal, Cameroun and Republic of Benin shows that this problem is a perennial land use challenge in virtually all African countries. This and other unwholesome land use perhaps have affected available usable per capital land. This assertion is further strengthened by Wit and Verheye (2007), they noted a sharp decline in Africa per capita available usable land, as record shows it nose-dived from 0.62ha in 1965 to mere 0.26ha in 1995. A decline was also noted in the available world's per capita usable land; the record shows a sharp drop from 0.39b ha in 1961 to 0.27 ha in the 1990s. Evidently, there are numerous marked evidences suggesting that unregulated human interference on residential land portends great danger to urban development in Nigeria. Consequently, the need to prioritise residential land use for optimum satisfaction unimpaired by graves becomes imperative.

Land Use Policy Framework; an Overview of Nigerian Urban and Regional Planning law

Land law and development control policies provide clear cut statements on the manner required for utilisation of land within urban areas in any country. Specifically, laws are a policy framework that ensures the use of land in an organized fashion. It helps to protect the maximum social and economic benefits of the present and future generations of land users. The Nigerian urban and regional planning law is the basis of all urban development and planning law in Nigeria. Following the provision of the Nigerian Urban and Regional Planning Act cap No.88 of 1992, each tier of government has responsibilities for exercising physical planning within the framework of the national physical development plan to ensure consistency in physical development at all levels of planning in the country. In order to achieve efficiency, equity and sustainability, the policy attempts to match different land uses with the greatest benefit at the least cost. This was to be achieved through developing national physical development plans at the Federal, State and Local government by establishing and maintaining namely;

(a) National Urban and Regional Planning Commission (Federal Commission).
(b) State Urban and Regional Planning in each state of the Federation (State Board).

(c) A Local Planning Authority in each Local government of the Federation (Local Authority).

The law mandated the Federal Commission, State Board and Local Authority to establish development control department. The development control department is a multidisciplinary department charged with the responsibilities of controlling developments and the implementation of physical development plans. The various development control departments at each level of government exercise control on land development within their jurisdiction and the provision of the law. Section 28 of the law stated that the approval of the relevant authority must be sought before any development can be embarked upon. It declares that mere application for certain development on land did not imply permission to embark on the development on land.

Grounds for Rejecting Some Development Proposals

Worthy of note is the provision of grounds for rejecting some application for land use developments considered as inimical to socio-economic utility. The following laudable grounds were provided for rejecting an application for development permit;

"Where the plan is not in accordance with the approved plan''

"Where the propose use is likely to cause nuisance to inhabitants of the community among others".

Provision for Remedial Actions against Development Contravention

In case of contravention to development approval, "stop work order is served in written form. This is followed by serving an enforcement notice within 21 days of the serve of stop work order. This is done to ensure that the developer restores the land to its original unimpaired state. The law makes provision for a penalty on individuals who disregard the stop work order or fail to comply with the terms of reference of the enforcement notice. A landlord that goes against this law is guilty of an offence and liable on conviction to a fine of not exceeding in case of individual ₦15,000.00K and ₦50,000.00K in case of corporate organisation. Alternatively, the development control department may choose to carry out demolition of the structure considered as nuisance to the occupiers or the public. A demolition notice is served containing a date not later 21 days for the demolition exercise with the cost of demolition paid by the offender.

Commentaries on Land Market and its Regulatory Framework

Access to land is encapsulated in two markets; viz formal and informal land market. The formal market is an offshoot of an attempt to nationalise land. Subject to promulgation of the Land Use Act of 1978, all traditional land tenure systems were repealed and all land in each state was vested in the state Governor. Among other objectives, it was believed that the statutory land law would guide and coordinate the land market. The informal land market is otherwise known as the private land market. Land parcels in this market are freely traded by family and individual with or without any formal records.

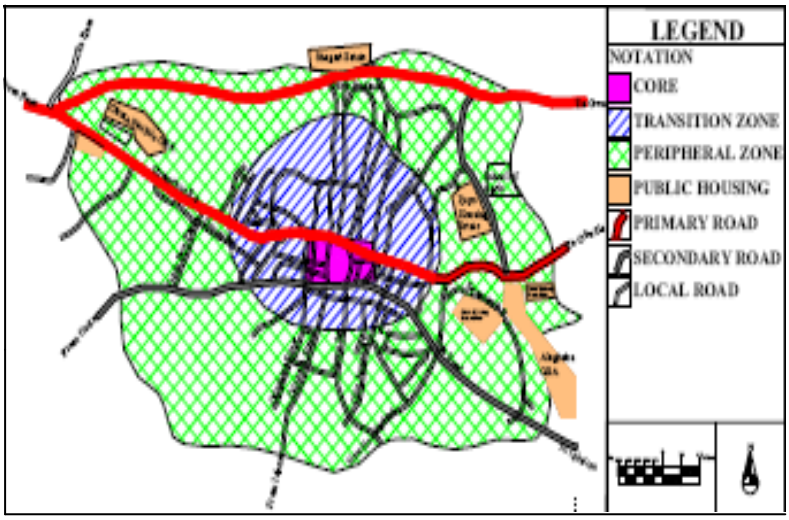
Despite the attempt to formalise the land market through promulgation of the Land Use Act, the informal land market continues to grow and represents the surest means of accessing land. This view is exemplified by different studies carried out by Mabogunje (2010), RICS (2010), Balchin (1995) and Dale (2000). They all observed

a land market operating in isolation and independent of any regulatory framework. They concluded that such an unguided market determines urban spatial structure and compromises the principle of equity, convenience and sustainable urban development. This view is supported by Mattingly (1991) in his study on urban land market in developing countries which revealed that mainstream planning practitioners' saddled with the responsibility of land use control show little awareness of the urban land market in which they intervene. Also, E.C.A (2006) noted that Nigeria and other African nations are facing common land policy issues; which are manifest in different historic, geographic, demographic, social and economic contexts. The study noted the gap between policy making and the documentation of successful implementation of such elsewhere. They opined that land use laws lack empirical knowledge of national and local circumstances and are generally not context specific.

Study Area

Akure is the capital and the largest city in Ondo State in South-western Nigeria. The city has a population of approximately 387,087. The people are of the Yoruba ethnic group. It is located on longitude $7^0$15'00"N and Latitude $5^0$11'42''E of the equator. Less than 10% of the city is made up of public housing while over 90% of the city comprises of private housing districts built on land purchased from informal land market.(See figure 1 for detail)

Figure1. Map of Akure Showing Private and Public Residential Estate.



Source: Ondo State Ministry of land and Housing 2012.

Research Methodology

This paper is basically anchored on observation and personal interview in a pilot study carried out on an on-going research work.

Sampling Technique

This study adopted cluster sampling technique because homogenous groupings are evident in the statistical population. Therefore twenty streets were randomly selected from different groups of residential areas in the city. These were carefully observed for evidences of graves on the residential properties.

 ISBN: 978-1-84219-840-7 .

Interview

Oral interview was conducted on telephone to elicit useful information from land officers in the ministry of land in the study area.

Notable Gaps in Urban Planning Law and Causes of its' Inefficiency in Akure

A striking thought is that land use laws are conceived as if they act by themselves which is contradictory to the principles of making and using laws. This view is consistent with Van and Beunen (2009) who asserted that space is only affected by laws after the laws are enacted. A major efficient performance requirement of any law is in its ability to explicitly spell out the dos and don'ts concerning a particular expectation on land use. The ambiguous nature of Nigerian urban regional planning law did not provide a list of land uses considered as nuisance on residential properties. Although this is considered as the nature of most laws whose efficiency is hinged on correct interpretation. Basically, it is inferred that urban planning laws are left to act by themselves. It might be erroneously believed that the occurrences of graves on residential properties were based on express approval of the urban development laws. This may be considered valid, as occurrences of graves would be deemed to have taken cognisance of section 28 of the law which requires approval of any proposed land use decision before its execution. Nuisance is one of the most complicated aspects of law; Prosser (1971) in Swanson and Konteleon (1999), *comments that "there is perhaps no more impenetrable jungle in the entire law than that which surrounds the word nuisance''.*

Basically, Anglo-American concept of urban planning conceives anything that violates zoning principles as nuisance. According to Swanson and Konteleon (1999), the emergent of new law and economics paradigm in the mid 20th century recognised that traditional nuisance law faced several doctrinal and practical shortcomings. Nuisance as one of the basis for rejecting application for some land uses has not been fully explored to deliver the inherent benefits of zoning. Responses from interview conducted in the Ministry of lands revealed a bias in the interpretation of the urban planning laws on private residential estate and Government residential estate. It was discovered that urban development impliedly assumed two parallel meanings to the term "nuisance" on graves. The first meaning perhaps permit graves on private residential land does not consider graves as nuisance. Efficiency of planning is further weakened by allocative inefficiency in the private land market which is at variant to the initial assignment of property rights.

The second meaning impliedly considers graves as a nuisance which should not be allowed on government residential estate. This interpretation of nuisance on residential property is noticeable in the terms and conditions for allocating land on government's residential estates. Prohibition of graves on Government residential land is expressly stated in the terms and conditions which any allotee must agree to before such land is granted.

The efficiency of planning laws to prohibit graves on residential properties' is further weakened by two parallel land markets (formal and informal) in operation. Regrettably, informal land market which is largely unregulated account for 80% of the land holding in Akure and most Nigerian cities. Therefore, it is obvious that the future of the city is in jeopardy if nothing is done to harmonise the working of the property market.

The Effects of Graves' on Property Transaction

The effects discussed here are absolutely based on result from observation and pilot study. Observation shows that vacancy rates are higher in residential properties with graves. This is further corroborated by simple Willingness to Pay survey (WTP) conducted on a group students. Out of 104 youth, only 1 student representing less than 1% was willing to buy a bare residential land/housing with grave. Conversely, the remaining 103 people show their willingness not pay any amount of money for such properties because of the stigma caused by imposition of grave on them. As this paper is a product of an on-going study which is largely concerned with the economic valuation of non marketed disservice; we believe that the effects of graves on economic value of residential properties will emerge from a wider perspective at the advance stage of this work.

CONCLUSION

The underlying argument of this paper is that, urban planning law is inefficient to prohibit location of graves on residential properties in Akure. It noted the provision against nuisance on residential land use; but the context has not been fully explored to clear the latent ambiguity in the polemic concept of nuisance. Therefore, it advocates a review of urban planning and development control laws to spell out prohibition of graves on residential land. This should be strengthened by highly empowered development control workforce for successful enforcement and high level of compliance. This step will help to ensure that property and development control are not left at the mercy of private landlords concept of highest and best use to the detriment of sustainable property transaction and development. It also suggests need to educate current land owners on the limitation of their property right and the need to transfer such right with an unimpaired value. This include recognition of transient nature of their right in a natural gift belonging to the past, present and unborn generation. Government should harmonise the two parallel land markets so that prohibition of graves on residential properties can be sufficiently interpreted within the context of nuisance on both private and government residential estate. Efforts should be channelled towards to acquiring more land from private landlords to increase the expanse of Government Residential land. This is necessary to reduce development of private residential land areas which are largely unregulated. In view of ambiguous nature of the planning and development control law, the author calls for periodic review to keep pace with changes in human behaviour which may constitute nuisance on residential properties. Finally, more attention should be devoted to the interpretation of urban planning laws to guarantee its' efficiency on both private and government residential areas.

Abstract:
Governing property development has always requires a holistic approach in decision making. The legislations for property development that are in placed still could not ensure the sustainability of development pertinently on highland and steep slope areas. These areas need more detail consideration and approaches specifically in the development process, implementation as well as the monitoring aspect. In lieu of that, the current planning, development guidelines and regulations have been evaluated as to examine the effectiveness of the current development mechanism in ensuring sustainable highland and steep slope development. Evidences from the case study have shown that the weaknesses lie in the decision making process, implementation and enforcement aspect of the property development process which have high influence in the property development growth and values. Besides, the study also revealed that property legislation setting should provide the implementation mechanism. Recommendations to ensure the prospect and sustainability of high land and steep slope development are emphasis on the needs in continuation of legislations and implementation procedures, monitoring actions as well as the necessity for the development players to collaborate and understand the important of sustainable development.

Keywords:
Highland, Legislations, Property Development, Steep Slope Areas, Sustainable.

1 Introduction

Malaysia has a complete, efficient and integrated guidelines and regulations thus; achievement of sustainable development should a non issue. The most crucial initial reference for development is the development plan which provides strategies and approaches in development with legalisation provision. It defined the allowable plot ratio, density, slope stabilisation requirement, mitigation, presevation of natural waterways, vegetation etc. However, those guidelines has weaknesses that need to be overcomed such as on the implementation and the intensity of the provision in those guidelines. The remedial is crucial to ensure the achievement of sustainble development and economic, social and environmental friendly development.

Major concerns in implementing these guidelines and regulations are the actors in development such as government agencies, politician, non-governmental organisation,

developer, businesses and the public. Achievement and success of the development implementation solely lies to the players. It needs a smart consideration on issues that arises during the implementation stage. Thus, knowledge, awareness, responsibility by all actors is crucial in order to achieve a balance development towards establishing sustainable development.

Continuous Geo disaster incidents especially in high land and steep slope areas need to be addressed accordingly. Public has stated the issues and concern on safety, land use planning, law and regulation, management, maintenance, accountability, funding and professionalism pertaining to development sustainability on high land and steep slope area. Basically public has lost their confident regarding to decision making which has been accommodated with planning and development tools, guidelines and regulation. The guidelines are not clear and some do not add value to safety, environmental protection and sustainability. Many issues are unclear and need improvement. The best thing is to get the local authorities to form a taskforce committee comprising professionals from the stakeholders who are familiar with hillside development to look at these issues and formulate clear and comprehensive guidelines and policies. Although there are existence of various regulations and guidelines for highland and steep slope development, issues such as geo-disasters, unsustainable development, public concern, effected development and economic growth remain unsolved. Based on the current development scenario and geo hazards incidents, it is foreseen that the development on high land and hill slope area requires a stringent legal and planning implementation procedure. Thus, it will affect the prospect for future property development in high land hill slopes area. It is crucial to search for the best approach and guidelines for sustainable high land hill slope development that is aligned with property development growth.

Economic Planning Unit (2002), defined high land as areas located at the height level of between above 150 meter from sea level. The definition was futher emphasised which emphasised on permissible development by National Physical Plan for Environmental Sensitive Area (ESA, 2005) as only areas with contour above 150 meter - 300 meter (ESA Rank 3) is permissible with controlled development where the type and intensity of the development shall be strictly controlled depending on the nature of the constraints.

2 Property Development in Highland and Steep Slope Areas

2.1 Legal Framework

In the development process, there are other related laws such as Town and Country Planning Act, 1976, (Act 172) Local Government Act, 1976 (act 171), Environment Quality Act, 1984, Uniform Building By Law, 1984, Street Drainage and Building Act 1974 etc. Beside those laws there are guidelines such as planning guideline, environmental guidelines, buildings guideline etc. Furthermore, development plans are prepared under the Town and Country Planning Act, 1976 (ACT 172) base on National Development Planning Framework comprises of three level such as national, state and local level. These plans provide a integrated top down development plan and strategies focusing on physical, environment, economic and social aspects towards vision 2020 (national development objective) (Bruton, 2007)

The governmental machinery which lies on Federal Constitution provides further avenues of federal influence over the state governments. Such influence is exercisable over matters that

are even listed under the state list of the Constitution (Hamzah, 2009). The four other national councils, the National Council for Local Government (NCLG) under article 95A, the National Land Council (NFC) under Article 91, and the National Finance Council (NFC) under Article 108 and National Physical Plan Council (NPPC) under chapter 2, ACT 172 are chaired by the Prime Minister or his appointee. Representatives both from the federal and state governments sit in these committees (Bruton, 2007).

The governmental machineries has been further strengthen by various agencies such as Ministry of Housing and Local Government (MHLG), Ministry of Natural Environment (NRE), Town and Country Planning Department (TCPD), Department of Geology and Mineral (DMG), Department of Environment (DOE), Department of Road and Work (DRW). These agencies and regulation are the tools to deal with development pertaining to High Land and hill slopes development. National land Code, 1965 set the provision pertaining for land matters, whereby land matters is state matter and decision on the land development were made by the State Executive Committee (EXCO) (Bruton, 2007).

2.2 Highland and Steep Slope Development Scenario in Selangor, Malaysia

The changes on the Malaysian geographical setting generally has effects on high land and hill slope development. It is showed that the geo disaster in Malaysia have started since 1919 and causes lost of life, properties and effected the economy. Major concern for high land and hiil slopes development increased during the Highland Tower, Bukit Antarabangsa collapsed on 11 December 1993 and the geo disaster continues with higher fequency and nos. since 2004 to 2009. The New Straits Times reported on 12 June 2006, that eighty per cent (80%) of Hulu Klang is at risk of landslides and that a soil expert said a study done two years ago showed that some areas in Hulu Klang sat on "schist rock", the weakest rock on which to carry out any sort of development.

Previously the geological aspect seems to be neglected in planning development. The geological setting is among the most important aspect that need to take into account in examine any development. The awareness of geological and geographical setting that change upon climate changes and natural disaster is still lacking in the decision making. However, the State of Selangor has responded to the geo disasters incidents and issues, the state of Selangor government has taken action to ban the development on High Land and hill slopes that have class III and IV catogery in 2nd April 2008. The action was taken by the government to prevent and control more disaster from hapenning. However, it has effected the property development and economic growth as a whole. According to Hutchison, banning development on hillsides is a good measure because it will minimise the clearing of natural vegetation (Hutchison, 2009). On the other hand (LPHS, 2008) 136 development projects classified under class III and IV are on hold classified which had direct effect on property development growth. In lieu of the drastic decision,. Various parties such as REHDA, developers, investors have appeled to the state government to reconsider the decision to cater the development constraints problem in Selangor and the effects on the economic and development growth and property values. (State of Selangor, 2009). However, Kong (2009) argued that it is is unfair to developers because many have purchased land and have outstanding bank loans to service. With the ban, there are less available land to build on. and faced financial losses. There have been many misconceptions regarding such developments. Class 4 slopes (more than 35°) had been successfully developed in countries like Hong Kong and Taiwan (Gue, 2009).

The following are incidents of landslide which have been occurring regularly on and along the hills situated in Hulu Kelang :-

i. 1985 - Taman Melawati, Jln G1
ii. 1993 - Highland Towers
iii. 1999 - Athenaeum Tower
iv. 2000 - Bukit Antarabangsa
v. 2001 - Taman Hijau
vi. 2002 - Taman Melawati, Jln G1
vii. 2002 - Taman Hillview
viii. 2006 - Kpg. Pasir, Taman Zoo View
ix. 2007 - Taman Melawati, Jln H1 and H5
x. 2008 – Bukit Antarabangsa

(source : Mineral and Geosciences Department, State of Selangor, 2010)

2.3 Reviewing Guidelines for Hill Slope Development

According to a census carried out by Real Estate and Housing Developers Association (REDHA) in 2010, there is an estimated 1,800ha of hillside land in Selangor valued at about RM1.4bil. According to the Cheif Minister State of Selangor, many developers have urged to reconsider and made a number of appeals to review the guidelines set earlier, where all Class 3 and Class 4 development was banned. (The Star, 2009)

There are fifth teen hillside housing estate in Ampang and Pandan areas which is next to Bukit Antarabangsa have been identified by the Selangor Government as being at risk of landslides. These areas will now come under continuous monitoring by local authorities. The areas identified are Bukit Antarabangsa, Ukay Heights, Taman Hijau, Taman Hillview, Dataran Ukay, Taman Melawati, Ukay Perdana, and Taman Kemensah. In the Pandan constituency, the risky areas are Taman TAR, Bukit Sungai Seputih, Bukit Teratai, Bukit Permai, Taman Saga, Taman Mega, and Bukit Segar.

State of Selangor topography consist of 47% of high land. Development on high land and hill slope area started in the middle of 1980's and grow rapidly in early 1990's and continues to present. The State of Selangor Planning and Development Direction has indicated land use distribution of the Selangor comprises of 39.7% for built up develop area, 30 % for forest 30% for agriculture and 21% for water body (2.1%). Thus, it limits the development area and has put pressure and demand for land which resulting violation on high land and hill slope as the best option to cater the demand. In light of the many hillside tragedy, Selangor state has drafted new development guidelines for Class 3 (more than 25-to-35 degrees) and Class 4 (35 degrees and above) slopes. Class 4 slopes, the most critical area with a combination of slope angles and located 150m above sea level or higher, are protected under the Land Conservation Act.

2.4 Development Issues on Highland and Steep Slope Areas

Chan (1998) mentioned that landslide and hill slope development are not new in Malaysia. The desire for rapid economic development in order to catch up with the developed world is often over-emphasized and this can lead to an unbalanced development strategy which often sacrifices environmental principles purely for the sake of economic gains. Chan (1998) indicated that forest clearance, whether due to logging, farming, housing or other environmentally damaging human land uses have significantly altered hydrological parameters. Chan (1998) also discovered in Malaysia, the natural elements, particularly the

weather elements, are highly erosive. Geomorphological processes such as rain splash erosion and surface run-off erosion have been shown to be extremely high in wet equatorial areas. Given the high intensity of our rainfall within short durations, the erosivity of rain and run-off are main causes for loosening the soil, weakening slopes and ultimately leading to mass movements of solid and semi-solid materials such as soil creep, landslips and landslides. Ooi, 2009 mentioned that the recent Bukit Antarabangsa high profile landslide also happened during a period of incessant rainfall with the failure of a 20-year-old tip-fill uncompacted slope. Poor drainage maintenance and tip-fill slopes were again the common factors that caused landslides.

Chan (1998) also discovered that cleared areas are not immediately replaced by concrete or other surfaces but left for considerably long periods before projects are finished. For example, the average duration of a housing project may take between a year to a few years. Thus, this leaves the cleared surface exposed to the elements of nature. Tan (2008) has further supported chan statement in light of the latest landslide tragedy at Bukit Antarabangsa in Ampang. Gue (2009) further added that the Highland Towers collapsed because the wall and slopes were not properly engineered and the drainage not properly done. The abandoning a hillside project would not necessarily make the place safe. Hutchison (2009) quoted that engineered slopes are never 100% safe as it lies on layers of sandstone and mudstone sitting on overlying limestone and rainfall volume. Faisal (2009) further added that features of unsaturated residual soils indeed very important. It is difficult to assess slope stability using analytical methods, as well as the use of vegetation for the prevention of slope failures. However, Ng, 2009 believes that zero maintenance is not the solution, as it may be very costly. All hills may end up as concrete hills as a result. Zakaria, 2009 agreed that deep cuttings would require high maintenance cost by the local authorities. Chen (2009), has pointed out that with the existence of so many agencies; everybody wants to be part of the solution. However, it seems to be running in all directions, thus he suggested that perhaps it should be centralised to one agency and monitored established panel of slope. Even if the houses have been given the Certificate of Fitness (CF) by the authorities, hillslopes are so vulnerable to the harsh realities of the Malaysian weather and all to frequent rainfall that would render the CF to be not worth the paper it's printed on (Bernama, 2009).

Kwan (2009), urged that there must be a proper policy, legislation and regulation governing hill-site development to make it sustainable which a stronger political will, a holistic approach and the involvement of professional and industrial players. Five points to urge the authorities to consider implementing comprehensive measures for high land and hill slope development as follows (Ng, 2009):.

i. The relevant authorities need to carry out a survey and classification on existing hill slopes nationwide on the development worthiness and identify those critical areas prone to erosion and landslide, and inform the public of the findings.
ii. Concrete policy and regulation on how hill slope development should be regulated and implemented.
iii. The authorities need to setup a specialised agency to oversee the formulation of policy rules and regulations on safe development and maintenance on hill slope development as well as the implementation and enforcement of these rules and regulations.
iv. The developers have to ensure that any future hill slope development is safe for the habitation of house buyers.
v. Responsibility and liability are currently insufficient. We want to make those culpable accountable, impose on them a stiffer penalty and imprisonment because we are

dealing with human lives.

Chan (1998), highlighted Malaysia's commitment towards environmental protection is clear, as there are policies, laws, regulations and EIA requirements in developments which can have an effect on the environment. Unfortunately, however, despite this commitment (and its international stance against environmental degradation),. Furthermore, Hutchison, 2009 finds that EIA reports that are very thick but are filled with all sorts of technical jargon and equations that do not being well understood, thus it seems uninformative. Many aspects of Malaysia's environment on the local front is still being exploited and degraded by irresponsible parties Chan (1998).

Ng (2009), pointed out that hill slope development today was not any safer than it was 16 years ago. As the guidelines consisting of the four classifications of slopes, Class 1-4 , was the only thing that we could access to. Furthermore, there were no other proper hill slope development guidelines that are accessible to the public. However, Dahlia (2009) pointed out that the Federal Department of Town & Country Planning places the development of programmes and community related to the conservation of natural resources, environmental protection and social stability as a priority. These priorities are translated into the National Physical Plan and also the National Organisation Plan, as well as the state level plans and district plans. These plans were based on policies and guidance for developmental procedures or planning commission procedures by the local planning authority. Zakaria (2009) expressed concerned about the development proposals of very steep and very high cut slopes that do not include comprehensive study on site assessment. It also need further emphasised on the important to look at upstream and downstream development as well, and come up with something comprehensive Chen (2009).

3 Objectives of the Research

The research objectives are as follows:

i. To examine the issues and problems of property development on high land and steep slope areas.

ii. To evaluate the effects of current planning and development guidelines and legalisation on property development and property value for high land and steep slope development.

iii. To examine the property development prospect and sustainability on high land and steep slope areas.

4 Methodology

The research focused on the development issues, implementation problems and property development prospect pertaining to property development in highland and steep slope area. The analysis has been carried out on the provision of planning and development guidelines and development plan, physical development trend and property values. Data was collected from various technical department and government agencies such as Town and Country Planning Department, State of Selangor, Mineral and Geosciences Department, State of Selangor, Ministry of Federal Territory, Ministry Of Natural Resources and Environment,

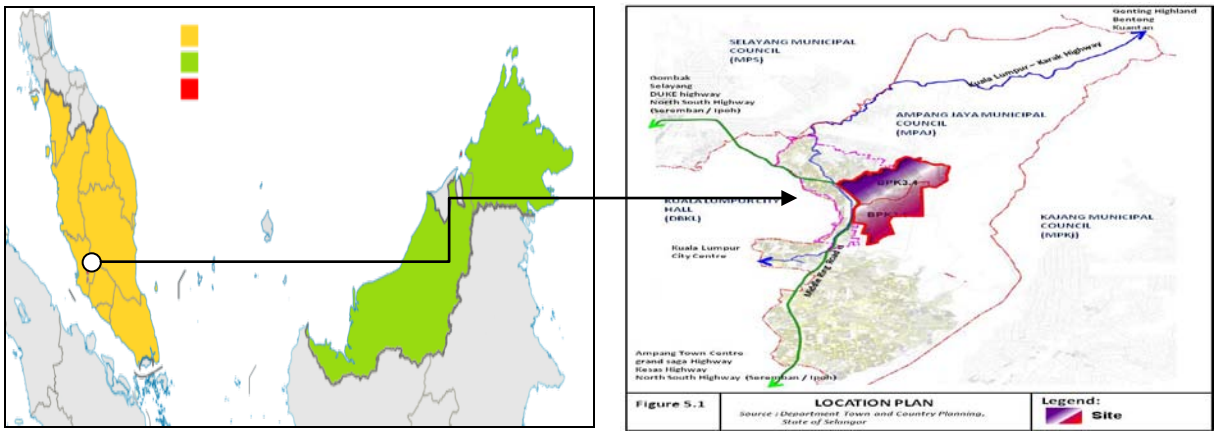
Malaysian Meteorology Department and Valuation Department, State of Selangor and Ampang Jaya Municipal Council of which will base on secondary data. The fundamental basis of data collection is referred to the case study in Bukit Antarabangsa, State of Selangor. The analysis was based on the study areas and other secondary data including government policy, development plan, property reports, planning regulation and guideline for high land and steep slope areas development.

5 Analysis of Findings and Discussion

The data is analyse and evaluated to measure the effects of the current guidelines and regulation on property development, property value and on high land and steep slopes areas.

5.1 The Case Study Site

The case study site is located at the western part of Gombak District (Mukim Hulu Kelang) in the State of Selangor and is bounded by the Federal Territory (Kuala Lumpur City Hall) jurisdiction area). The study site is under the jurisdiction of Ampang Jaya Municipal Council. Ampang, State of Selangor and is an established development area consists of existing, committed development and preserve areas. Generally, the study site is a built up area, which dominantly developed with housing. The Major Land use for the study site is housing of various types commercial, agriculture and forest area in an area of 914 hectares (2,267 acre). 82% of the study site is developed. The rest of the site comprised of undeveloped land, patches forest (part of Ulu Gombak Forest Reserve) and agriculture area which is 18% of the total study site. The study site has been permitted for development mainly for housing and commercial. *(Figure 5.1)*



The study site is built up area and land for development is limited. The study site is located at a strategic location surrounded by developed area, major towns and highly accessible for major road and highways that connects locally and regionally. However, the study site generally in unstable position in physical development context due to numbers of geo-disasters occurs within and adjacent to the study site. Development for this area need to be monitored and considered based on stringent planning control. It requires continuous monitoring, maintaining and managing mechanism in the implementation processes. The crucial aspects that need to be focused are on safety, environmental preservation and development sustainability. Thus, planning and development guidelines need to be precised, stringent and implementable.

5.2 Planning and Development Guidelines and Regulations for Highland and Steep Slope Areas Development

Planning and Development Guidelines and acts pertaining to hill land and steep slope development has been developed since 1970's. Those guidelines and acts was formed in policy, regulation, legislation, guidelines and implementation procedures to ensure a sustainable high land and steep slope areas development. The current Planning and development Guidelines and legislations for High land and Steep Slope development has been developed since 1997 to 2010 are as follows:

i. Ampang Jaya Draft Structural Plan 1995-2020, 1997
ii. National Physical Plan,2005
iii. High Land Development Guidelines, Ministry of Environmental and Resources, 2005
iv. Draft Guidelines for the Conservation and Development of Environmental Sensitive Area and its Surrounding Area, 2005
v. State of Selangor Structure Plan 2020, 2007
vi. Planning Standards Guidelines Selangor of Selangor, 2007
vii. Ampang Jaya Draft Local Plan 2020, 2009
viii. Development and Planning Guidelines for Hilly and High land Area, Ministry of Housing and Local Government, 2009
ix. Development and Planning Guidelines for Hilly and High land Area, State of Selangor 2010

Planning and development guidelines and regulation regarding to high land and steep slope area has been developed since 1997 until 2010 either in policy form or implementation guideline form. There are 9 related planning and development guidelines for high land and steep slope area have been referred for permitting development. There are various emphasises and considerations on approaching the control mechanism for high land and steep slope area development. Thus, the current planning and development guidelines will give impact towards the property development and property value on high land and steep slope areas. It has been indicated that the guidelines has under gone an evolution in dealing with the development trend and approaches which led to the changes of the guidelines variables as well as it emphasising towards stringent and stricken development requirements. The changes are as shown in **Table 5.1- Appendix A.**

The consideration in permitting development and its density as indicated in the current guidelines was based on the followings variables:

i. Development Suitability classes
ii. Height / contour level
iii. Slope gradient
iv. Environmental Sensitive area (ESA) classes
v. Risk Classification.
vi. Technical report such as such as Development Proposal report, Geo-Technical Report, Erosion and Sediment Control Report, Environmental Impact Assessment Report and Earthworks Plan.

Prior to 2005, the variables used was slope gradient and risk classification that allow high, medium and high density development in low laying areas and low and medium risk area. Restriction for development on high land and steep slope areas covers for steeper and higher risk area as well as emphasising on topographical preservation. In 2005, the policies and

 ISBN: 978-1-84219-840-7 .

guidelines for high land steep slope area has use more variables that emphasise on Development Suitability classes, height / contour level, slope gradient and ESA. However, the risk classification variables have not been taken into consideration. In term of policy making, NPP emphasise on ESA and height / contour level. It is foreseen that the concern is more towards environmental preservation and slope stability, and the direction was express in the policy. The policy indicated allowance for medium and high density development in low laying areas and low and medium ESA area. Restriction for development on high land and steep slope areas covers for higher and riskier area and emphasis on topographical preservation. For implementation wise, the guidelines changes the emphasis by using Development Suitability classes, Slope gradient, ESA require technical report. These guidelines allow for low and medium density development in low laying areas and low and medium ESA area. Restriction for development on high land and steep slope areas covers for steeper and higher ESA area and emphasis on topographical preservation. In 2007, the planning and development policy and guidelines has neglected the consideration of Development Suitability Classes and Risk Classification. For the policy making purpose, only slope gradient is used as the variable. The policy emphasised on slope stabilisation in the sustainable environmental context. This is use as a basis for further implementation of the guidelines. The implementation of the guidelines has incorporated height/contour level, slope gradient and ESA classes as the variable and also requires technical report submission. The guidelines permitted development for low, medium and high density development in low laying areas. Restriction for development on high land and steep slope areas covers for higher area and ESA area and emphasis on topographical preservation.

In the first half of 2010, the planning and development guidelines concentrated on Development Suitability classes, height / contour level and slope gradient as the variables. However, on the second half of 2009 and first half of 2010 the guideline strongly emphasis on the development Suitability classes, height / contour level as the variable and requirement for technical report submission. The guidelines permitted development for low, medium and high density development in low laying areas. Restriction for development on high land and steep slope areas covers for higher area and Class IV area and emphasis on topographical preservation. It was revealed that the major concern in high land and steep slope development is the topographical preservation towards safety, environmental and physical sustainability. Changes in variables indicated the importance of the development suitability classes and height / contour control. The verification development suitability classes are taken into consideration the geological setting, slope stabilisation, risk and environmental consequences, thus it is a comprehensive variables. It is seems that the changes shows some inconsistency in approaches of controlling for high land and steep slope area development. Generally low, medium and high density development is permissible on low lying area. For high land and steep slope areas, low and medium density is permissible. However, for higher land especially categorize as class III, low density is permissible with stringent requirement for technical report such as Development Proposal report, Geo-Technical Report, Erosion and sediment Control Report, Environmental Impact Assessment Report and Earthworks Plan to be submitted for development evaluation. For Class IV and higher land level, any kind of development is not permissible except for infrastructure such as road, tunnel, bridge, telecommunication & electric tower. Even then, the development guidelines should be amended whereby it needs to take a holistic consideration of all variables used during the changes to avoid mislead and to confirm for best development control on high land and steep slope area.

5.3 Physical Development Trend and Encroachment

 ISBN: 978-1-84219-840-7 .

Early development in the study site began in highlands and steep slope area. The early development approaches were low and medium density development with no reference on development and planning guidelines. It shows that development issues has not emerged and does not effecting the environment, physical, economic and social sustainability. The need for planning and development guidelines is seemingly less important by looking at the development growth in 1990 to 1993 that encroaches to highland and steep slopes areas. The highland tower incident in 1993 shows some indicator for the need of planning and development guidelines especially concerning on safety, mitigation, slopes maintenance, geological inputs etc. As highlighted, there were no development activities in 1994 to 2004. Thus, Ampang Jaya Structure Plan 1997 was in place which imposing policies and guidelines pertaining to highland and steep slope development with consideration of those factors.

Various development plans, planning and development guidelines were in place in 2005-2010. However, those guidelines are varies on the emphasis aspects and variables. The common concentrations of those guidelines were on the environmental sustainability and topography preservation. Those guidelines are incrementally to be more stringent in permitting development and impose various technical reports to ensure development's sustainability. Having those guidelines, the development has growth rapidly in 2002-2010. However, there were doubts regarding to the guidelines efficiency and effectiveness as refer to the 4 geo disaster events happen in the study site in 2004 to 2010. The pertinent issues that need to be address is the allowable development density and mitigation measures for high land steep slopes development. It is foreseen other aspects should be the main concern such as monitoring, maintenance, enforcement, responsibility, liabilities etc that need to be imposed to stakeholders on highland and steep slope development. It is shown in **Figure 5.2 – Appendix B.**

5.4 Impact on Property Development and property value in high land and steep slope areas

5.4.1 Fluctuation in the property prices in lieu of the geo-disaster (landed and strata)

The geo-disaster events have given a huge impact on the property prices in Bukit Antarabangsa particularly to the affected areas such as Bukit Antarabangsa, Taman Hillview and Taman Bukit Mewah. The analysis below demonstrated the fluctuation of property prices in those areas for strata as well as landed property.

5.4.2 Strata property – Puncak Athenaeum Condominium (Bukit Antarabangsa)

Puncak Athenaeum is a 340 unit of condominium housed in two towers of 21-storey. Located in Jalan Wangsa, Bukit Antarabangsa, the condominium was collapse in 1999 which caused 4 deaths.

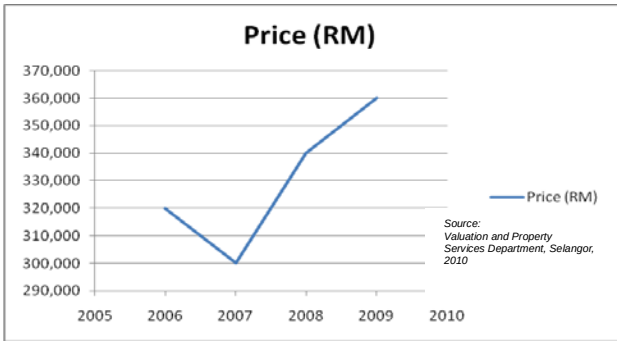
It was shown that the prices of Puncak Athenaeum starting from year 1991 were appreciated until the year of 1998. Unfortunately, the values of the condominium unit were fall off on the following year due to the geo-disaster tragedy. The percentage of fall is approximately 30% from the preceding years (1998) due to the fear factor as well as the tragedy that scared potential

 ISBN: 978-1-84219-840-7 .

purchasers and investors away for security reason. The condo prices were continued to fall until year 2000. As shown, there were no transaction recorded between year 2001 and 2002 as purchasers has no confident to buy the condo in lieu of the tragedy and the possibility of the geo-disaster to repeat within the short period of time. The property value for the said condominium was badly hurt. Nevertheless, purchasers' confidents were started to grow as there were transaction recorded in the year of 2003 but with depreciate price. The prices of the condo unit were stagnant up to year 2006. Year 2007 and 2008 recorded an appreciation of price for approximately 4%-8% of the preceding year. The recent data transaction (2009) recorded the depreciation of the condo price. This is assumedly due to the 2008 Taman Bukit Mewah tragedy as purchaser and potential were scared that the same tragedy will again happen to Puncak Athenaeum Condominium.

5.4.3 Landed Property – Terrace Houses (Taman Ukay Bistari)

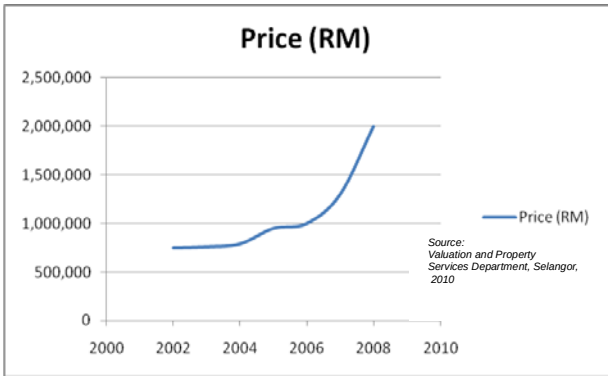
The Kg. Pasir tragedy that occurred end of 2006 has slightly impacted its surrounding property such as Taman Ukay Bistari that located at the southeast boundary of Kg. Pasir. The fluctuation of property prices particularly landed property i.e. terrace houses are as shown below.



The price of the terrace houses in Taman Ukay Bistari for the year 2006 was recorded before the tragedy which was around RM320, 000. The following year after the tragedy recorded a slight fall approximately 6% of the price for the preceding year. An approximately 13% growth in price were recorded in 2008. It shows that the Kg. Pasir tragedy does not give a significant impact towards property prices in its adjacent neighbourhood. The latest transaction (2009) recorded a further increase for the terrace houses in Taman Ukay Bistari as the confident level of the potential purchaser and investors toward that area has restored.

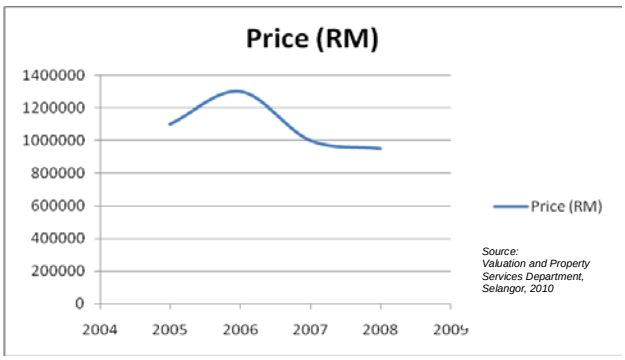
5.4.4 Landed Property – Semi-D (Taman Beverly Heights)

Another most famous landed property in Bukit Antarabangsa area apart from terrace and
bungalow is semi detached house. Taman Beverly Height is chosen a this area is located further away from any geo-disaster area that have occurred in Bukit Antarabangsa such as Taman Bukit Mewah, Kg. Pasir, as well as Taman Hillview (not included in the study area). Taman Beverly Height which was approved in 2002 sold its semi-d at RM750,000. The transaction data in the following year recorded an increase to RM760,000. As shown in the above table, the price of semi-d houses in Taman Beverly Height was continuously increased up to the latest transaction recorded in 2008 for RM2.0 m. It is obviously shown that the price of semi-d in the said area was not affected by any geo-disaster tragedy in Bukit Antarabangsa i.e. Kg. Pasir and Taman Hillview (not included in the study area) which occurred in 2006. Thus, it can be concluded that not all geo-disaster that



occur in Bukit Antarabangsa area would affect all property prices within the vicinity, some may still appreciate depending on the safety and confident level of the potential purchaser and investors.

5.4.5 Landed Property – Bungalow (Taman Bukit Mewah)



Taman Bukit Mewah tragedy in late 2008 has raised many speculations and issues in lieu of the safety for development in hill side and hill slope area. Tragedy that killed 5 people has resulted to the review as well as enforcement of additional guidelines pertaining to hillside and hill slope development. The price of bungalow prices in Taman Bukit Mewah was recorded at 1.1 m in the year 2005. There were increments approximately 18% in the following year (2006). The sale prices were declining in the year 2007 was due to the Kg. Pasir and Taman Hillview (not included in the study area) tragedy which gave fear to the residents especially to bungalow residents. The prices were continued to decrease to 950,000 in 2008 as the confident level were still low. The Taman Bukit Mewah tragedy which occurred during end 2008 has worsened the scenario. There were no transactions recorded in 2009 as the tragedy that has snapped up 5 lives is still fresh in everyone's memory.

6 Conclusions and Recommendations

Generally, the present legislation, development and planning guidelines are relevant and friendly to the property development specifically for the high land and steep slope development. However, the main concern is on the inconsistency of variables used in the guidelines that neglecting important aspect such as environmental sensitivity and category of allowable development. As at 2009, the development and planning guidelines has consistently aligned and uniformed all variables and provisions required in permitting development which strictly emphasised on environmental sustainability, topographical preservation, safety and mitigation aspect. However, the improvement and remedial actions need to be concentrated in implementing development continuously. Therefore, sustainable high land and steep slope development could be achieved as well as to safe guard the property value.

The present development guidelines for highland and steep slope area do not give a huge impact on the development growth as evidenced by the development trend in the study area. The analysis also revealed that the property value in the study area are still maintained and sustained throughout the year even though the current development guidelines has outlined certain restriction as well as imposing stringent development control for certain area on highland and steep slopes development. The only concern that threaten the property value on the above said area is the unforeseen geo-disaster events that beyond human control. In lieu of the unpredictable of climate changes, there are many unimaginable disasters that may happen especially to disaster-prone area such as Bukit Antarabangsa.
Nevertheless, those depreciated property value will not last longer. This is a result of the revision of the existing planning and development guidelines pertaining to highland and steep slope area especially after each tragedy, and we can see that the mushrooming of new development on the surrounding areas (i.e. tragedy area) right after the enforcement of those

new guidelines.. Therefore, it can be concluded that, the present planning guidelines pertaining to high land and steep areas development specifically to the study area are suitable and generally sufficient to sustain and to boost up the existing development prospect.

As mentioned above, the current planning and development guidelines are generally friendly to the current development and so far, it has taken into consideration all important technical aspects pertaining to highland and steep slopes development by requiring all technical reports that assure that the proposed development are align with the carrying capacity for that particular area before development can be approved. Nevertheless, the main concern now are on the implementation, enforcement, as well as continuous monitoring of those guidelines as well as on the flexibility of those guidelines to new development concept such as SOHO, Superlink house, etc.

The crucial facts revealed from the analysis of the study site was the needs for sustainable development which emphasis that the development for highland land and steep slope area need to be considered and monitored based on stringent planning control. The geo-disaster tragedies generally give an impact to the depreciation and appreciation of property values. Thus, the development for this area requires continuous monitoring, maintaining and managing mechanism in the implementation processes. The crucial aspects that need to be focused are on the safety, environmental preservation and development sustainability. Therefore, planning and development guidelines need to be précised, stringent and implementable as recommends in Table 6.1:

Table 6.1: Suggestions for Better Monitoring of Highland and Steep Slope Areas:

No	Suggestion	Explanation
1.	Development Monitoring System	The authorities need to form a monitoring system for high land and steep slope development which will monitor, evaluate and enforce any misconduct of development implementation. The monitoring system should be supported by information technology (IT) such as inventories high risk development, geo-disaster prone area, slopes area, property ownership and etc.
2.	Flexible Planning and Development Guidelines	The planning and development guidelines should be amended and incorporates flexibility aspects. The flexibility should be given for new development concept and approaches such as the usage of high technology material and system that will ensure the development's safety and sustainability. Therefore, the permissible density for instance can be upgraded
3.	Trade off in Complying to Development Provision	Development provision should be considered in giving allowance for trade off. For instance, since class III is only permitted for low density and needed for high financial and class IV is restricted for any kind of development, the provision to accommodate low cost houses should be forfeited and leverage on expatriates ownership.
4.	Legislation Review	As the environmental sustainability and topographical preservation is a crucial aspect to be considered in permitting development, review on the enforcement of the current legislation need to take place. For instance, the provision for trees and topographical preservation as indicated in section V, Town and Country Planning Act, 1976. However, in previous development, the implementation of the provision has not been implemented. Therefore, the said provision should be embedded in the earthwork approval and the trees and topography need to be inventories. Another aspect that need to be embedded in the legislation is the property's owner responsibility towards slope maintenance as well as to effected neighbouring lot from the property development activities. This responsibility should be stated in the land or property title and in should be for perpetuity.
5.	Propose Best Planning Practices for Sustainable High Land and Steep Slope Development	Demand for sustainable development is increasing nowadays. Challenges in dealing with sustainable development implementation are mainly on safety assurance, environmental preservation and physical environmental stability. Thus, the emphasis in planning and development is on the environmental control, natural topography, greeneries, natural waterways and best living environment. Best planning practices

		should be implemented to ensure development implementation sustainability.
6.	Special Area Plan	High land and steep slope area need to be developed systematically and continuously monitored. It is suggested that the Special Area Plan which is a comprehensive plan is mandatory to be prepared for high land steep slope development. It indicated a suitable development area and development implementation approaches. However, the special area plan needs to be enhanced by incorporates financial projection, construction methods, enforcement provision and geological requirements.
7.	Green Development Concept	Highland and steep slope development should impose green development concept which emphasis on natural physical environment and bio-diversity. The important development component is the soft landscape consist of matured trees (existing trees in the development land should be preserve as referred to section v, Town and Country Planning Act, 1976), preservation on natural water ways, scrubs and etc. It should also incorporate the new development technologies such as the green building, energy saving design and appropriate building materials that blends with the natural environment.
8.	Low Density Development	Development on highland and steep slope area should strictly allow for low density only. The development layout must accordance to the topographical terrain and design for minimum earthwork. The new development concept that maximise development plot which is the of balance plinth area, single loading entrance, contemporary and traditional design should be encouraged and to be blended with greeneries components.

In a nutshell, there are always a huge prospect for property development growth and sustainable and increment in property value on highland and steep slopes area in relation to the reviewed planning and development guidelines.

ABSTRACT

Recently, the demand for Liquefied Natural Gas (LNG) has continuously increased. Also the number of new contracts for LNG plant construction is predicted to continue to increase. In particular, the procurement phase is crucial because it is the largest portion of the Engineering-Procurement-Construction (EPC) project from a total project cost perspective. So, when the problems are incurred by supply vendors such as schedule delay or under performance product, then huge amounts of liquidated damages and additional procurement cost are emerge. So, optimal supply vendor selection to achieve the expected schedule and performance is critical. Nevertheless, variety and complexity of criteria for selecting vendors, despite the research, is insufficient to generalize it. It has resulted in several limitations of current supply vendor selection models. To this end, we develop a Fuzzy-TOPSIS -based model to enhance the reliability of the supply vendor selection process through investigation of the limitations from current models and the characteristics from LNG plant. Then the model is confirmed by applying it to a procurement case in LNG plant projects. Consequently, the suggested model can enhance reliability in the decision making process for supply vendor selection through well-structured, multi-criteria decision making processes and fuzzy logical quantifications.

Keywords: Decision-Making Process, Fuzzy-TOPSIS Method, LNG Plant, Procurement, Supply Vendor Selection Model

INTRODUCTION

In recent decades, the demand for Liquefied Natural Gas (LNG) has continuously increased based on energy security issues and interest in sustainable and green technology. According to the Intergovernmental Panel on Climate Change (IPCC, 2007) report, LNG is a cleaner form of energy than other fossil fuels, such as coal and oil, in terms of greenhouse emissions. The report reveals that the emission coefficient of LNG is smaller than those of other fuels. Moreover, the reserve-to-production ratio is larger than those of other fuels, meaning that we can use LNG as an energy resource for a long time and with fewer negative impacts on Earth. Demand for LNG will experience more growth than will other energy resources (International Energy Agency, 2011). Similarly, demand for LNG plant construction is rapidly increasing.

[1]* shh6018@yonsei.ac.kr (corresponding author)

Nevertheless, LNG plant construction projects face large barriers because of their own diverse characteristics, such as their large scale, complex mechanisms and low-temperature and high-pressure processes. Therefore, LNG plant design requires a more experienced and skillful approach than do other types of plant design. Specifically, the procurement phase is the most important phase because it accounts for up to 60% of the total project cost and requires unique and strict standards. Therefore, effective and efficient management is directly connected to project success. Generally, procurement describes delivering a suitable product in the planned amount of time to an exact location with the required level of performance and safety. In addition, procurement is performed by contractors and vendors through time, cost and quality management. If the schedule delay or under performance occurred, then the owner faced huge amounts of economic damages. Damages must be transferred to contractors and vendors as liquidated damage. Moreover, re-construction or re-procurement is performed to achieve the expected performances with additional cost and time. To achieve successful procurement, both the contractors' abilities and vendors' abilities are crucial. Several abilities of supply vendors such as technical standards, expected performance, quality/safety/cost control, lead time, strategic relationship and etc. affect the procurement process and its performance, so they needed complex and well-structured Multi-Criteria Decision Making (MCDM) processes that decision making method using various decision criteria for the optimal supply vendor selection. Consequently, procurement should be performed carefully and the decision support model is crucial for the successive supply vendor selection.

PROCUREMENT AND SUPPLY VENDOR SELECTION

Procurement in LNG plant projects

Procurement is intensively related to other processes, such as contracting, design and construction. In addition, it also follows the construction plan. So, procurement processes should be based on the project's own characteristics. In this reason, selection of reliable supply vendors is will not only reduce the risks for the other sub-phases of procurement, but will also enhance the stability of the construction plan. An LNG plant has unique characteristics of both a general plant and specialized LNG. It makes more difficulties to select optimal vendors for an LNG plant. The Ministry of Land, Transportation, and Maritime affairs (MLTM) of Korean government described the properties of a general plant as a "complex and technology-intensive system" and a "standard-based industry" that involved "dynamics of plant technology" (2007). These are considered fundamental to project success. In addition, an LNG has more scientific and skillful characteristics, such as "limitation of license to liquefaction", "material corrosion in preprocessing", "low-temperature (-162°C) and high-pressure processes" and "safety problems, such as leakage and explosions" (Jang, 2011; Hong, 2012). These concerns strongly affect not only the material selection and design change but also the weight of criteria for vendor selection. So, to satisfy the above concerns, the supply vendor selection process should be managed carefully with investigation of LNG plant characteristics.

Approaches for Supply vendor selection

According to Monczka et al. (1998), the purposes of supply vendor selection can be summarized as follows: 1) minimize the procurement risks, 2) maximize the value for the customer and 3) establish a long-term and stable relationship. To achieve these aims, Chen (2006) suggests certain guidelines. He emphasizes the criteria

composition based on both qualitative and quantitative perspectives, multiple participants for reducing bias and variability from uncertainty or environmental change. Since the Dickson's research (1966), which suggests the total 23 criteria based on expert survey, many of researches focused on MCDM processes as price, quality, delivery and their service (Weber et al, 1991; Pi and Low, 2009; Chen, 2006). However, most of the literatures focused on the identification of selection criteria over the concerns about quantifications of qualitative criteria. Therefore, previous approaches have limitations in supporting the project manager's procurement decision and management efficiency. Along these same trends, research for construction projects was actively performed. They also suggest the criteria, but some criteria are considered the characteristics of construction projects as past performances and relationships (Ng, 2008; Watt et al, 2010). Nevertheless, this research is limited at the generalization of various expert opinions and the consideration of individual differences in propensity. As a result, existing vendor selection method contained some disputes at the objectivity and rationality perspectives.

FUZZY-TOPSIS–BASED VENDOR SELECTION MODEL

Benefits of Fuzzy-TOPSIS method in LNG plant project

The fuzzy concept was introduced by Zadeh (1965) for making decisions among unclear opinions. It can convert "crisp" contents to "fuzzy (numerical)" languages through the use of "membership functions". It is frequently used to solve MCDM problems in which the problem contains some crisp content. The fuzzy approach yields more realistic results for decision making by eliminating the biases in unclear contents. The Technique for Order Performance by Similarity to Ideal Solution (TOPSIS) was introduced by Hwang and Yoon (1981) to solve MCDM problems. The TOPSIS fundamentally assumed that a Positive Ideal Solution (PIS) exists in the near-to-best solution alternatives and that a Negative Ideal Solution (NIS) exists in the near-to-worst solution alternatives. Therefore, the technique suggests both the best and worst alternatives. Finally, fuzzy-TOPSIS is a combination of the above two theories and was introduced by Chen (2000). He tried to perform decision making using the fuzzy method for linguistic variables and TOPSIS for mathematical calculations. It provided more reasonable and rational results for decision making.

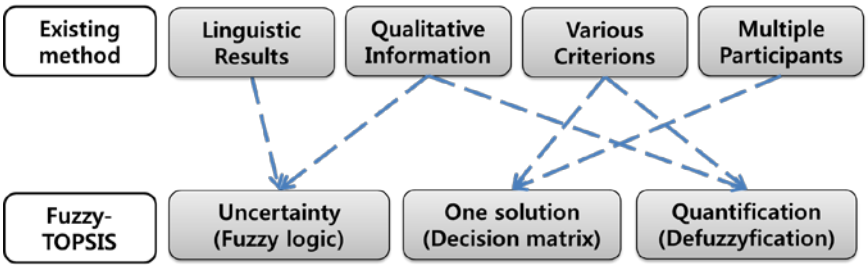

Fig. 1. The Benefits of Fuzzy-TOPSIS Method

According to these characteristics, we identified the benefits of the Fuzzy-TOPSIS method in LNG plant projects (Fig. 1). It can calculate the one solution from complex evaluation results by multiple experts. In addition, fuzzy logic makes various membership functions to minimize the uncertainty and the bias during quantification of linguistic terms. Also, the defuzzification process makes qualitative expert opinions into quantitative evaluation results. Consequently, the fuzzy-TOPSIS is an improved method from the existing models by using the well-structured MCDM process and the

fuzzy logical quantification method. In fact, it can provide a back-up for the uncertainties using membership functions, weighing each criterion and eliminating the bias in vendor evaluation using mathematical matrices to quantify the qualitative criteria using the defuzzification method.

Fuzzy-TOPSIS-Based Vendor Selection Model

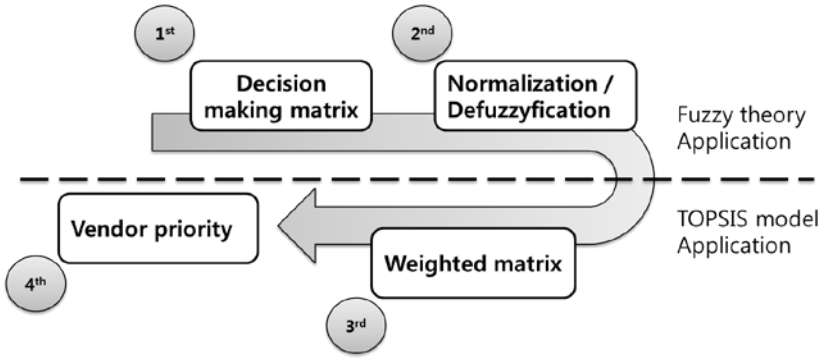

Fig. 2. Flows for the Fuzzy-TOPSIS Method

To establish the supply vendor selection model for an LNG plant considering the above claims, we performed several steps, as shown in figure 2. To choose optimal criteria for supply vendor selection, we performed a broad literature search on decision criteria. Seven studies on frequency analysis were extracted from the literature that focused on vendor selection or vendor evaluation. As a result, four criteria were selected: “price”, “quality”, “delivery” and “relationship (contract experience)”. However, these criteria were focused on general construction projects. Additional criteria must be considered to define the characteristics of an LNG plant project.

$$D = \begin{array}{c} \\ A_1 \\ A_2 \\ \vdots \\ A_m \end{array} \begin{array}{cccccc} C_1 & C_2 & \cdots & \tilde{C}_{n-1} & \tilde{C}_n \\ x_{11} & x_{12} & \cdots & \tilde{x}_{1n-1} & \tilde{x}_{1n} \\ x_{21} & x_{22} & \cdots & \tilde{x}_{2n-1} & \tilde{x}_{2n} \\ \vdots & \vdots & \vdots & \vdots & \vdots \\ x_{m1} & x_{m2} & \cdots & \tilde{x}_{mn-1} & \tilde{x}_{mn} \end{array}$$

$$W = [w_1 \;\; w_2 \;\cdots\; w_n] \qquad \text{……(1)}$$

The characteristics of LNG plants have already been mentioned as concerns. Comparing these concerns with the four selected criteria, we also extract the additional criterion of “technology ability”. The MLTM method (2007) emphasizes plant technologies and their dynamics. After reviewing the literature, we conducted expert interviews to confirm the extracted criteria. Experts commonly noted that the first four criteria should definitely be considered, and they required additional criteria for “safety” and “maintenance”. If the facility or equipment develops a leak, then a terrible accident could occur. Moreover, the processing resources and products of an LNG plant are flammable. Therefore, safety is more important than the other criteria. Ease of maintenance is suggested by a longer plant life cycle. Finally, we chose seven criteria for supply vendor selection in an LNG plant project (price, quality, delivery, relationship, technology, safety and maintenance). This paper established the use of the fuzzy TOPSIS model for supply vendor selection in an LNG plant project. It

consists of two parts: the fuzzy application and the TOPSIS application. The fuzzy application consists of two subparts. The first step is the development of a decision matrix to quantify the qualitative variables. D is the decision matrix, A_n is the nth supply vendor and C_n is the nth criterion. W_n is the weight of criterion C_n (equation 1).

$$r_{ij} = \frac{x_{ij}}{\sqrt{\sum_{i=1}^{m} x_{ij}^2}} \quad \ldots\ldots(2)$$

The second step is the normalization of D. Each criterion has different measuring units. Therefore, the measuring units were unified to facilitate direct comparison using equation 2, where r_{ij} is the normalized value of criterion C_j. Next, defuzzification of the fuzzy matrix is performed. Generally, a fuzzy calculation consists of three phases: fuzzification, fuzzy inference and defuzzification. However, this paper does not use fuzzy inference, which involves a combination of membership functions. In addition, the center of gravity method is used for the defuzzification.

$$z = w_j r_{ij} \quad \ldots\ldots(3)$$

$$A^+ = \max(w_j r_{ij})$$
$$A^- = \min(w_j r_{ij}), i = 1,2,\ldots,n \quad \ldots\ldots(4)$$

The third step is the reflection of the weight on the decision matrix. In this step, the weighted decision matrix is created using the normalized (and defuzzified) matrix and its relative weight (Hwang et al, 1981). Equation 3 shows the calculation of the weighted decision matrix, where w_j is the weight of the jth criteria. Then, a TOPSIS calculation of PIS, NIS and the relative closeness is performed based on the weighted decision matrix z (equation 3). Equation 4 shows identification of PIS and NIS as A^+ and A^-, respectively. To calculate the relative closeness between the ideal solution and weighted matrix, we use the Euclid distance method. Equation 5 shows two of the closeness values; d+ refers to the distance between the PIS and each weighted matrix, and d- refers to the distance between the NIS and each weighted matrix.

$$d_i^+ = \sqrt{\sum_{j=1}^{n} (A^+ - w_j r_{ij})^2}, i = 1,2,\cdots,m$$

$$d_i^- = \sqrt{\sum_{i=1}^{n} (A^- - w_j r_{ij})^2}, i = 1,2,\cdots,m \quad \ldots\ldots(5)$$

The fourth step is vendor prioritization using the results of the TOPSIS calculations. Vendor priority is measured by the closeness coefficient (CCi), as shown in equation 6. CC consists of d values. According to Hwang et al. (1981), the ideal solution of the CCi estimate is one, and the non-ideal solution of the CCi estimate is zero. Consequently, the vendor priority is determined by the scale of CCi.

$$CC_i = \frac{d_i^-}{d_i^+ + d_i^-}, i = 1,2,\cdots,m \quad \ldots\ldots(6)$$

ILLUSTRATIVE CASE APPLICATION

To confirm the applicability of the suggested model, we perform a descriptive case application. It requires inputs for the opinions on each criterion and the relative weights. Then, all of the opinions go to the fuzzy TOPSIS model, which acts as a translator through normalization, defuzzification, PIS and NIS. Finally, the priority of the supply vendor is determined by the CC produced as output.

Table 1. Weight Evaluation of Each Criterion (Sample)

	Price (P)	Relationship (R)	Quality (Q)	Delivery (D)	Technology (T)	Safety (S)	Maintenance (M)
Expert 1	SH	H	H	M	VH	H	SL

A case study was performed using the above procedures. Three experts who had at least 15 years of experience in the LNG construction area, participated in the case study. In addition, they are also currently working on an LNG plant project as managers. Each expert evaluated the relative weight of the criteria using a fuzzy-based, seven-level linguistic scale: very low(VL), low(L), somewhat low(SL), medium(M), somewhat high(SH), high(H) and very high(VH). Table 2 shows the results of the evaluations.

Table 2. Evaluation Results from Experts (Sample)

	Vendor	P	R	Q	D	T	S	M
Expert 1	A	20	2	H	VH	H	M	SL
	B	18	3	VH	SH	VH	SH	SH
	C	16	5	M	SH	M	H	M
	D	25	1	VG	H	H	SH	SH
	E	23	2	H	SH	H	H	SH

Additionally, each expert evaluated five supply vendors using the seven suggested criteria. Price and relationship are not different because we used the same project and product. The above two tables contain all of the inputs. Next, we present the fuzzy TOPSIS calculations. The normalization and weighted decision matrix are calculated based on tables 1 and 2. In addition, the arithmetic mean is used to summarize the various expert opinions. Table 3 shows the calculation results of the weighted decision matrix.

Table 3. Results of Weighted Decision Matrix (Sample)

Vendor	P	R	Q	D	T	S	M
A	0.43	0.26	0.52	0.51	0.84	0.46	0.17
B	0.46	0.39	0.45	0.32	0.72	0.65	0.32

After calculation of the weighted matrix, the CC is determined. To determine the CC, the PIS and NIS of each criterion were calculated by equations y and y, and then the clone values (d+ and d-) were calculated. Finally, the CCs are determined using the closeness values. Table 4 shows the fuzzy TOPSIS results. According to these results, vendor E is the optimal supplier. In fact, vendor E's price is the highest, and the relationship (contract experience) is average. This result would not have been

produced by the traditional approach. Nevertheless, these results reveal that price is only part of the decision; various criteria are crucial to minimize bias. Moreover, these results extract a number of expert opinions through a mathematical approach.

Table 4. Final Results of Vendor Prioritization

Vendor	A	B	C	D	E
CC_i	0.435	0.689	0.686	0.592	0.699
Rank	5	2	3	4	1

DISCUSSION AND CONCLUSIONS

Optimal supply vendor selection is a crucial factor from the project performance and success perspectives. Procurement can account for up to 60% of the total project cost. This paper develops a supply vendor selection model for LNG plant projects. We extracted seven criteria for LNG plant projects through character investigation, expert surveys, and interviews. We then established a supply vendor selection model for LNG plant projects using the fuzzy TOPSIS method. Finally, to confirm the applicability of the suggested model, we performed a case study. According to the case study, the suggested model can enhance the reliability of the decision-making process by proving mathematical evidence. Nevertheless, this approach cannot be directly applied to various real cases. In addition, only three experts participated. These limitations are barriers to the generalization of this study that could be addressed with additional research. However, this paper developed a reliable supply vendor selection model that can be used to summarize a number of expert opinions through a mathematical approach. Consequently, the suggested model can be used as a guideline for making optimal supply vendor selections in LNG plant projects.

ACKNOWLEDGEMENTS

This research was supported by a grant from the LNG Plant R&D Center funded by the Ministry of Land, Transportation, and Maritime Affairs (MLTM) of the Korean government.

ABSTRACT

Value engineering uses analytical, creative and evaluation techniques on a multi-disciplined basis to achieve the desired functions in a design. The aim of this study is to investigate the use of value engineering process within the construction industry in Lagos, Nigeria. The study was conducted through personal interview and administration of structured questionnaires to selected construction companies, consulting firms and construction professionals who have been involved in the application of value engineering for their projects. The respondents were selected using systematic random sampling technique. The data collected were analyzed using using distributive and inferential statistics. The findings of the study revealed that the packaged review, the truncated workshop, the charette , the concurrent workshop and the contractors change proposal are significantly used in VE study. In carrying out value engineering job plan emphasis should be placed on development phase, implementation phase and evaluation phase. The major challenge of value engineering study is that it is time consuming. The study strongly recommends that value engineering study methods that are in constant use should be examined in details to identify areas of improvement. Efforts should also be made to reduce the time spent in carrying out value engineering study on a project.

Keywords: Construction projects, Cost reduction, Function analysis, and Value engineering

INTRODUCTION

Today many clients are increasingly concerned with the achievement of value for money in their construction projects. In addition, building owners are more conscious not only in cost of construction, but also in the value of buildings in terms of fulfilling its basic functionalities (Lozon and Jergeas, 2008). Providing better solutions or benefits to clients by increasing the value of a project is the foremost objective in the construction industry. Not only the clients but also the project participants are always concerned about project value improvement, but investment capital is a scarce commodity, and clients are striving to use their available capital in the most efficient and effective ways(Hee and James, 2006). In view of meeting these awesome challenges, value engineering came into focus. Value engineering is a process whereby team efforts are made to understand the functions of a system in order to realize the essential functions of that system at the lowest life-cycle cost (Younker, 2003). Value engineering is the systematic application of recognized techniques

[1] Onukwube12345678@yahoo.com

which identify the function of a product or service, establish a monetary value for that function and provide the necessary function at the lowest overall cost (SAVE international, 1998).

According to Palmer, Kelly and Male (1996), Value engineering (VE) developed during World War II in the United States. It began as a search for alternative product components, a shortage of which had developed as a result of war. Due to the war, however, these alternative components were equally unavailable. This led to a search not for alternative components but to a means of fulfilling the function of the component by an alternative method. It was later discovered that this process of function analysis produced low – cost products without reducing quality and after the war, the system was maintained as a means of both removing unnecessary cost from products and improving design. The process of value engineering based on analysis of function was born.

Perera, Hayles and Kerlin (2011) is of the opinion that value engineering is orientated towards providing the best possible product (building) for the client, by providing a process that guarantees that the various personnel involved throughout the entire building life cycle are aware of the needs and functions the particular building must satisfy. This then ensures that these functions and needs can be fulfilled at the most favourable cost, hence providing optimum value for money. Value engineering has become a proactive, problem solving or solution seeking process, which can be used to enhance the functional value of a project by managing its development from design concept to operational use and eventual decommissioning , through structured, team-oriented and open-dialogue exercises, which recommend alternative or confirm existing solutions, and appraise subsequent decisions, by reference to the value requirements of the client (Hayles et al., 2010). Value engineering addresses the key issue of function in relation to cost to achieve maximum value for the client (Hayles and Simister, 2000), providing the client with the means to help ensure that their investment in construction produces a valuable asset, one which is cost-effective to construct, use and maintain. Thus, the emphasis is on functional performance and ensuring the client gets what they need and want from their investment.

Value engineering specifies ways to think about the problem and its constraints, using the concept of value and by identifying what things actually do; their function (Fong, 1999). Value is the relationship between cost and performance: a measure of what is achieved for a given level of effort. In this context, “cost” embraces all relevant costs and functional performance embraces all stakeholder requirements (Kelly et al., 2004). A standard methodology for the application of value engineering has become widely established and it is often referred to as the ‘job plan’. The methodology advocates a systematic approval to the value engineering process. The detail of the “job plan” varies according to the timing within the project and the scope of the value study. At the outset, the job plan is focused on identifying and establishing a balance between competing stakeholder objectives and then throughout a project, the job plan focuses on options appraisal and refinement of design and activity to deliver best value for the clients and other stakeholders (Kelly et al., 2004).Extant literature points to the fact that much research in the area of value engineering process had been done in other parts of the world (Lozon and Jergeas, 2008; Mao et al; 2009; Pulaski and Horman; 2005) and appraisal of value engineering in construction(Palmer et al; 1996; Akintola; 2001) but little research has been recorded in this domain of study in Lagos, Nigeria, hence the need for this study. Within this context, the aim of this study is to investigate the use of value engineering process within the construction industry in

Lagos, Nigeria. Issues identified for investigation included: Extent of usage of value engineering formal methods, significance attached to various phases of value engineering job plan and factors affecting the growth of value engineering in Lagos, Nigeria.

VALUE ENGINEERING PROCESS

A Value engineering process contains three sections, pre workshop, workshop, and post workshop. During the value engineering process, a multidisciplinary team reviews the project plan and assesses the possibility of improving the project value. In the construction industry, value engineering is normally conducted at the early design stage. However, value engineering should not be ruled out at the construction stage as the contractor's practical experience and expertise, innovative construction plan and construction methods, and improved construction logistics management can also lead to substantial cost savings, better quality, and earlier project completion. The key stage of the VE process is the workshop session, which includes information and function analysis phase, creativity phase, and evaluation phase. The creativity phase is the most decisive stage, in which the brainstorming technique is usually applied to generate innovative ideas for enhanced project functions and reduced project costs (Mao, Zhang, and AbouRizk, 2009). The workshop phase are collectively referred to as the job plan. The job plan provides a vehicle to carry the study from inception to conclusion and logically separates the study into distinct tasks. It assures that consideration is given to facts that may have been neglected or overlooked in the creation of the project. Every step of the process is geared toward obtaining a result that increases the ROI (return on investment) or value for the client. Therefore, written documentation is maintained as a record of the process as it progresses. This documentation is formalized into a verbal and written presentation. Success is ensured by adherence to the job plan. The job plan highlights and focuses attention on the pertinent issues, essential needs, criteria, problems, objectives, and concerns of the project. The phases included in a typical value engineering job plan are described in the following.

- ***Goal Definition Phase***—during this phase, the goal is clearly defined and boundaries are established. The purpose is to ensure that efforts are not wasted on non-essential tasks.
- ***Information Phase***—this phase requires the team to capture as much information as possible about the project background and estimated costs.
- ***Function Analysis Phase***—Function analysis forces the team to think in new ways and to think outside the box. Every aspect of the project is described through the use of two word functions (active verb, measurable-noun descriptors) and placing those functions in a decision-logic diagram.
- ***Creativity Phase***—during this phase as many ideas, processes or methods as possible are generated by which the previously defined functions can be performed. This is typically accomplished through brainstorming sessions. No critical judgments or comments are allowed during this phase that might inhibit creative thought. At this phase the focus is on the quantity of ideas not the quality of ideas. At this stage idea such as material substitution, relaxing tolerances, standardizing customized items, combining elements and altering the construction sequence should be considered.
- ***Evaluation Phase***—This is the point in the job plan when the ideas generated in the previous phase are evaluated. The purpose is to assess those ideas that have the greatest probability for implementation. Each idea is examined

individually as to feasibility, cost, and value received. These ideas are tested against the criteria and limitations established in the goal defining phase. In addition, economic analysis, life-cycle cost analysis, tradeoff analysis and sensitivity analysis are performed to better evaluate the value of each idea. Ideas can also be rated on safety, reliability, environmental impact, aesthetics, maintainability and other non-economic considerations.

- ***Development Phase***—the purpose of this phase is to take the remaining ideas from the evaluation phase and develop them into workable value engineering recommendations. The recommendation proposal provides enough information to allow informed decisions to be made. A typical proposal will describe the recommendation, cost of implementing the recommendation, advantages and disadvantages of implementing the recommendation, and supporting data such as sketches, calculations, life cycle cost sheets.
- ***Presentation Phase***—an informal briefing of the value engineering process and results is given to the decision makers. This provides an opportunity to clarify any misunderstandings between project requirements and the value engineering recommendations.
- ***Implementation Phase***—at the client's options any or all value engineering recommendations are implemented. Follow-up may be required during this phase to ensure the recommendation is properly developed by the architect or engineer.

The first hypothesis postulated for this study is: All phases of value engineering job plan as used for VE study in Lagos, Nigeria are not significant.

Value Engineering Methods

There are a number of different methods through which the Value engineering process can be implemented. According to Phillips (2002), the choice of method to use may be dependent upon the type of project and the objectives of the client. The 40-hour workshop is considered to be the most comprehensive implementation of the value engineering process and takes five full working days to complete. This traditional approach to the value engineering process is highly time consuming and expensive, but can provide best results (Kelly and Male, 1993). A shortened version of this process, which some refer to as a "design charette" may be adopted. This generally takes between one and three days to (Kelly et al., 2004) and is the preferred approach as it is shorter and costs less in terms of up front time and resourcing. Kelly and Male (1993) opined that "The Concurrent Workshop" involves the use of a project team under the control of a value manager to review construction alternative on a regular basis during the pre contract phase of a project while "The Contractor change Proposal" is a change inspired by the contractor after the contract has been awarded. The "Truncated Workshop" is used for projects with small contract value and usually consists of a team of six multi- disciplinary members. The "Packaged Review" is commonly used in management forms of contract. This is used where a detailed appraisal of each package (trade or element) is undertaken by the project team as an ongoing process transcending the pre - contract and construction phase of a project. It also involves discussion with specialist contractors and building contractors.

The second hypothesis postulated for this study is that: the various VE methods in use are not significant.

CHALLENGES OF USING VALUE ENGINEERING

Some project stakeholders may perceive value engineering as a critique of their own design by others resulting in negative attitudes and resistance to implementation of value engineering recommendations (Norton and McElligott, 1995; Kelly and Male, 1993; Ellis et al., 2005). Fong (1999) argues that whilst value engineering has grown in popularity, there is still a lack of understanding of the principles of the process amongst some clients and construction professionals. This lack of knowledge can provide resistance to its use, and in the case where it is implemented, the process will not be as successful. Another problem that is common with value engineering implementations relates to timing of value engineering implementation. Ellis et al. (2005), contend that using value engineering at later stages often manifests as a cost cutting exercise rather than preserving or improving value. This perception that value engineering is frequently viewed and applied by some organizations strategically as a cost cutting exercise is shared by Hayles et al. (2010).

RESEARCH METHODS

A mixed mode research methodology was adopted for this study. It involved the use of personal interview to gather broad views of organizations that use value engineering in their construction projects in Lagos, Nigeria. Structured questionnaires were administered to the identified organizations through systematic random sampling technique. The ranges of issues included within the survey instrument were drawn from literature (Perara et al; 2011, Lozon and Jerges, 2008; Palmer et al; 1996).Out of 300 establishments that were identified to have used value engineering technique on their projects, one out of every two establishment were selected and given questionnaires. A total of 94 questionnaires were collected and used for the study. The population sample was drawn from client, consultancy and contracting organizations and this comprises architects, civil engineers, quantity surveyors, builders, mechanical and electrical engineers.

DATA ANALYSIS AND RESULTS

The statistical analysis of the data obtained was carried out with the aid of Statistical Package for Social Sciences (SPSS). Six methods that can be used in carrying out value engineering on a project were identified and used for the study. Responses on the frequency of use of eight phases of the job plan were also sought from the respondents. The respondents were required to rate the frequency of use of each method using 1 for never, 2 for rarely, 3 for sometimes, 4 for usually and 5 for always. And the respondents were required to evaluate the importance attached to various phases of the job plan. The usage and importance index were computed using mean item scores. These scores were then ranked in descending order. The reliability of the survey instrument was tested using the Cronbach alpha reliability test. The Cronbach reliability coefficient alpha is 0.913 with F- statistic of 48.612, $p = 0.0001$ indicating the measuring instrument is reliable at the 5 percent significance level.

Table 1 shows the result of professional status of the respondents. The majority of responses were received from Quantity Surveyors 30(31.91%), this is seconded by Architects and Builders 18(19.15%). Others are Civil Engineers 12(12.77%), Mechanical Engineers 10 (10.64%e) and Electrical Engineers, 6(6.38%). The

responses from quantity surveyors is the highest, this suggests that they are more involved in the practice of value engineering in their respective projects. This corroborates the findings of Perera et al; (2011).

Table 1: Professional Status of Respondents

Professions	Frequency	Percentage (%)	Cumulative Percentage (%)
Quantity Surveyors	30	31.91	31.91
Architects	18	19.15	51.06
Builders	18	19.15	70.21
Civil Engineers	12	12.77	82.98
Mechanical Engineers	10	10.64	93.62
Electrical Engineers	6	6.38	100.0
Total	94	100.0	

The first hypothesis postulated for this study is that all phases of value engineering job plan as used for VE study in Lagos, Nigeria are not significant.
Results in Table 2 indicates that the implementation phase, development phase, function analysis, evaluation phase, information phase, goal definition, presentation and creativity phase have their chi- square calculated values (χ^2 cal =20.65, 18.00, 16.27, 13.45,13.02, 10.67,9.85, 9.81) higher than their chi- square tabulated values (χ^2tab = 3.84, 3.84, 3.84,3.84,3.84,3.84,3.84,5.99), it means alternative hypothesis (H1) which states that all phases of value engineering job plan as used for VE study in Lagos, Nigeria are significant is to be accepted

Table 2: Chi-square test result on Phases of Value Engineering Job Plan

Factors	χ^2cal	DF	χ^2tab	P- Value	Sig	Decision
Implementation phase	20.65	1	3.84	0.000	S	Accept H1
Development phase	18.00	1	3.84	0.000	S	Accept H1
Function analysis	16.27	1	3.84	0.000	S	Accept H1
Evaluation phase	13.45	1	3.84	0.000	S	Accept H1
Information phase	13.02	1	3.84	0.000	S	Accept H1
Goal definition	10.67	1	3.84	0.000	S	Accept H1
Presentation phase	9.85	1	3.84	0.000	S	Accept H1
Creativity phase	9.81	2	5.99	0.018	S	Accept H1

The second hypothesis postulated for this study is that: the various VE methods in use are not significant.

Results in Table 3 indicates that the packaged review, the truncated workshop, the charette, the concurrent workshop and the contractors change proposal have their chi-square calculated values (χ^2 cal =13.42, 12.39 10.17, 7.23,6.39) higher than their chi-square tabulated values (χ^2tab = 3.84, 3.84, 3.84,3.84,3.84), it means alternative hypothesis (H1) is to be accepted for these cases. The 40 hour workshop have their chi- square calculated value (χ^2 cal = 2.47) lower than chi- square tabulated value (χ^2 tab = 5.99) thus the null hypothesis is to be accepted for this case.

Table 3: Chi-square test result on Methods of Value Engineering Job Study

Factors	χ^2cal	DF	χ^2tab	P- Value	Sig	Decision
The packaged review	13.42	1	3.84	0.000	S	Accept H1
The truncated workshop	12.39	1	3.84	0.000	S	Accept H1
The charette	10.17	1	3.84	0.000	S	Accept H1
The concurrent workshop	7.23	1	3.84	0.000	S	Accept H1
The contractors change proposal	6.39	1	3.84	0.000	S	Accept H1
The 40 hour workshop	2.47	2	5.99	0.018	NS	Accept H0

Table 4 shows the summary of the responses to the statements related to factors affecting the growth of value engineering in Lagos, Nigeria. From the results in Table 4, the major factor affecting the growth of value engineering study on projects is that the process is time consuming (0.844), the next in ranking is the process is not implemented early enough(0.804). Others in descending order are: It is more focused on cost and not value (0.776), there is not enough personnel with correct knowledge to carry out the process (0.740); it is costly to carry out value engineering study (0.638) and it is more an assessment of the design teams work. The results in Table 6 is supportive of the findings of Perera et al;(2011) and Ellis et al; (2005) as they suggest that value engineering study is time consuming and the process is not implemented early enough at the design stage.

Table 4: Factors affecting the growth of Value Engineering

Factors	Mean item score	Rank
The process is time consuming	0.844	1
The process is not implemented early enough	0.804	2
It is more focused on cost and not value	0.776	3
Knowledgeable personnel to carry out the process is inadequate	0.740	4
Value engineering study is costly to carry out	0.638	5
It is more an assessment of the design teams work	0.616	6

CONCLUSIONS

This study was set up to investigate the use of value engineering process within the construction industry in Lagos, Nigeria. The test of hypothesis one shows that all the phases of value engineering job plan are significant in VE study. The implication of this finding is that the VE team should not neglect any phase of the job plan. The test of second hypothesis indicates that five methods of VE study are significantly used in Lagos, Nigeria in value engineering study. The study also revealed that value engineering study on a construction project is time consuming and value engineering process on a project does not start early enough during the design process. The study strongly recommends that value engineering study methods that are in constant use should be examined in details to identify areas of improvement. In the execution of value engineering job plan, all the phases of the plan should be taken into consideration most especially the development, implementation and evaluation phases. Efforts should also be made to reduce the time spent in carrying out value engineering study on a project.

BUILDING CONTRACTORS' SELECTION CRITERIA IN AKWA IBOM AND CROSS RIVER STATES, NIGERIA

Godwin Iroroakpo Idoro[1] and Ini Jackson Edimoh[2]

[1,2]*Department of Building, University of Uyo, Uyo, Akwa Ibom state*

ABSTRACT

This study examines the factors affecting construction contractors' selection in Akwa Ibom and Cross River states of Nigeria. The objectives are to determine the relative importance and consideration of selected criteria for selecting building contractors and to compare the extent of consideration of the factors in the two states. A questionnaire survey approach involving a sample of 72 projects was adopted. Data were collected using structured questionnaires and analysed using relative importance index, relative consideration index and Chi-square test. The result reveals that a multi-criteria method is adopted in the two states to select contractors and that contractors' experience, reputation and quality assurance and control are the hallmark of contractor selection criteria. It is therefore concluded that price is not a major criterion for contractors' selection in the two states. It is suggested that in order for contractors that operate in the two states to be competitive in their bids, they should give more attention to measures that will improve their performance than price.

Keywords: Building contractors, clients, contractors' performance, contractors' selection, Nigeria.

INTRODUCTION

Contractors play significant role in project success therefore, selecting a competent contractor is a challenge to clients. The task is a challenge because the construction industry is volatile, competitive and fragmented (Palaneeswaran and Kumaraswamy, 2000a&b; Fong and Choi, 2000; Mahdi *et al,* 2002). The process of selecting a suitable contractor may involve pre-qualification in which a large number of contractors are invited to submit a technical bid thereafter; some of them are shortlisted based on a set of pre-determined criteria. Hatush and Skitmore (1997a), Ng and Skitmore (2000), Lam *et al.* (2005) opined that pre-qualification process is aimed at minimising the risk of employing incompetent contractors. The next process involves selecting the most competent contractor from those short listed for the contract. The goal of every client is to engage a contractor that will deliver a project at a reasonable cost, to a reasonable quality and within a reasonable time. The most adopted selection methods particularly in public projects over-emphasise the selection of the lowest tender. Hatush and Skitmore (1997b), Fong and Choi (2000), Palaneeswaran and Kumaraswamy (2000a), Mahdi *et al.* (2002) and Banaitiene and

[1] iroroidoro@yahoo.com

Banaitis (2006) advocated a balance between cost, time and quality in the final selection of contractors and contended that in selecting a contractor, various criteria such as experience, technical capabilities, performance in past projects, financial strength among others should be considered simultaneously. Banaitiene and Banaitis (2006) opined that some issues that make the existing contractors' selection practice defective include the use of inappropriate criteria when evaluating the qualification of contractors. The duo affirmed that the existing practices contribute to time and cost overruns, variations, rework and failed projects and attributed the weakness in the existing practices to the use of inappropriate criteria such as tender price. In appreciation of this problem, this study examines the criteria used in selecting contractors for the award of building projects contracts in Akwa Ibom and Cross River States of Nigeria. The objectives are to determine the relative importance and consideration accorded selected criteria in the award of building contracts and to compare the consideration accorded the criteria in the award of building contracts between the two states.

REVIEW OF LITERATURE ON CONTRACTORS' SELECTION CRITERIA

Studies on the criteria for contractors' qualification and selection have found that price is the main criterion. However, Holt *et al.* (1995) observed that cost is obviously of prime concern but a balance is desirable between cost, time and quality in order to secure best all round value for money. They suggested that any alternative selection approach should integrate prequalification as part of the selection exercise, introduce a standard secondary investigative element, combine the latter with tender sum to generate a final combined score and identify the optimum contractor. This suggestion calls for a shift from price-based selection criteria to multi-criteria selection approach. Hatush and Skitmore, (1997b) remarked that contractors' prequalification and tender evaluation are decision-making processes that occur within the overall construction procurement strategy and that they involve the development and consideration of a wide range of necessary and sufficient decision criteria as well as the participation of various stakeholders. The duo suggested the use of a common set of criteria (financial soundness, technical ability, managerial capability, safety and reputation) as contractor selection criteria in the construction industry. Hatush and Skitmore (1997a) developed and advocated appropriate predetermined criteria and methods for selecting contractors and discovered that contractors' financial stability, experience, ability and management were perceived to be dominant criteria while contractors' safety and length of time in business were perceived to have least effect. Jennings and Holt (1998) found that experience, financial standing, attribute of key personnel and previous business relationship are important in contractors' selection but that clients attach ultimate importance to low price.

Ng and Skitmore (1999) discovered that a generalised set of decision criteria weighting is unlikely to satisfy both public and private clients and suggested that clients should be allowed to weight criteria in line with their organisational objectives. A conceptual benchmarking model for public sector clients was suggested by Paleneeswaran and Kumaraswamy (2000a). The model identified best practice in contractors' selection using "co-operative" and "non-competitive" approach. The duo described best practices as improved processes or approaches that have produced significantly better results compared to past and current results. In another study, Paleneeswaran and Kumaraswamy (2000b) investigated the assessment of tenderers

on the basis of ten key pre-selection criteria namely: finance, human resources, organisation and management, project specific requirements, past experience, past performance, technology, quality system, health and safety and equipment. The study identified quality accreditation and past performances as useful indicators although; they might not be perfect tools for predicting and guaranteeing better quality performances.

Fong and Choi (2000) contended that the existing selection methods over-emphasize acceptance of the lowest bid and suggested that the use of Analytical Hierarchy Process (AHP) will expose the strength and weakness of contractors. Wong *et al*. (2001) discovered that the construction industry in UK is moving toward a multi-criteria selection approach rather than the lowest-price approach. A Multiple Criteria Decision Support System (MCDSS) contractors' selection model was developed by Mahdi *et al.* (2002) using a combination of the Delphi method and the analytical hierarchy process. The model considered the specific conditions of a project and the capabilities and qualifications of contractors to perform a proposed project taking into account the project specific conditions. The purpose was to reduce the limitation due to individual judgement and increased fairness in decision-making. Topcu (2004) regarded the evaluation of contractors based on lowest tender as a major cause of project delivery problem and proposed a decision model based on multi-criteria approach for contractors' prequalification and choice of eligible bidder.

Although there is a consensus on multi-criteria selection approach in previous studies however, researchers express reservations about the approach because of the importance that should be given to each criterion in contractors' selection in order to achieve fair selection. Lam *et al*. (2005) observed that contractors' selection practices are complicated by subjectivity, uncertainty and consideration of a large number of criteria. Banaitiene and Banaitis (2006) contended that multi-criteria evaluation method may be used but due consideration should be given to clients' priorities. Ng and Skitmore (2000) suggested a transparent process in which the prequalification criteria together with any associated scoring, is made available to contractors. The duo opined that the selection of tenders relies heavily on the use of value judgements by decision-makers and that the experience of pre-qualifiers varies from organisation to organisation. They observed that the use of value judgements is a major source of bias in decision-making and prequalification cannot be exempted.

Studies on contractors' selection tend to attribute the failure of projects generally to contractors' incompetence. However; Elinwa and Joshua (2001) also discovered that factors such as inadequate finance, delay in payment of completed works, frequent changes in materials and design which are not related to contractors' competence contributed significantly to the failure of contractors.

RESEARCH METHODS

The study adopted a questionnaire survey design approach. In the approach, a field survey involving a sample of 72 projects was conducted in early 2011. To obtain the sample, a pilot study of recently completed projects in the study area (Akwa Ibom and Cross River States) was conducted in late 2010. From the survey, 97 projects were identified and adopted as the study population frame.

The variables of the study consist of 25 criteria for contractors' selection which are stated in Table 3. The variables were identified from literature and focus group discussion with the respondents during the pilot study and were measured for

respondents' assessment of their importance and extent of consideration in the award of the contracts of the projects sampled on a 5 point Likert-scale: nil, low, moderate, high and very high. The scale was adopted because it is appropriate for achieving the objectives of evaluating the relative importance and consideration of the factors. The ranks were rated 1, 2, 3, 4 and 5 respectively. To achieve the objectives, a research hypothesis was postulated. The hypothesis states that the ranks of the extent of consideration of contractors' selection criteria in the award of building contracts in Akwa Ibom and Cross River States in Nigeria are not significantly related. The result of the hypothesis is expected to ascertain whether or not the consideration of the criteria used for the award of contracts varies between the two states in Nigeria.

The data were collected using structured questionnaires administered by hand on the project leaders sampled who were engineers, quantity surveyors, architects and project managers. A sample of 72 projects was selected by stratified random sampling from the study population frame. The data were analysed to determine the level of awareness of the criteria by the respondents using Relative Importance Index (RII) and the extent of consideration of the factors in selecting the contractors of the projects sampled using Relative Consideration Index (RCI). Both RII and RCI were derived as the total score divided by the number of respondents. The research hypothesis was tested using Chi-square test.

RESULTS

Characteristics of Projects Sampled

Seven project characteristics were investigated. The results are presented in Table 1.

Table 1 Descriptive results of the characteristics of projects sampled

Characteristic	N	%	Characteristic	N	%	Characteristic	N	%
Project client			**Construction type**			**Project location**		
Private	19	26.4	New	63	87.5	Akwa Ibom State	45	62.5
Public	53	73.6	Rehabilitation	9	12.5	Cross River State	27	37.5
Total	72	100	Total	72	100	Total	72	100
Project duration			**Project cost**			**Project use**		
1-6 months	4	5.6	N1-50m	12	16.7	Office	33	45.8
7-12 months	48	66.7	N51-100m	14	19.4	Residential	10	13.9
Above 12 months	20	27.8	N101-500m	0	0	Educational	17	23.6
Total	72	100	N500m – 1b	7	9.7	Religious	3	4.2
Building rise			Above N1b	39	54.2	Recreational	9	12.5
Low (1-3 floors)	57	79.2	Total	72	100	Total	72	100
Medium (4-7 floors)	9	12.5						
High (above 7 floors)	6	8.3						
Total	72	100						

N=Number of projects sampled, m=million, b=billion

Table 1 shows that the study covers projects procured by both public and private clients and both new projects and rehabilitation works but new projects constitute the majority. On building rise, Table 1 shows that low, medium and high rise buildings were sampled but the majority are low-rise buildings. The results also show that projects sampled are buildings of different uses. The duration of the projects shows that the projects sampled were distributed over short, medium and long durations. The analysis of the value of the projects reveals that the majority of the projects sampled are large projects with value greater than N1 billion. On project location, Table 1 shows that the two states that constituted the study area were covered in the projects sampled.

Assessment of Importance of selected Factors affecting Contractors' Selection

The Relative Importance Index (RII) of twenty-five selected factors that affect contractors' selection stated in Table 3 was investigated. The importance of the factors on contractors' selection was measured on a 5 point Likert-scale as described in the research methods. Respondents indicated the rank that represented their perception of the importance attached to each factor in the award of the contracts sampled. The results are presented in Table 2

Table 2 Ranks of the relative importance and consideration of selected criteria for contractors' selection

Factor	N	Score	RII	Rank	N	Score	RCI	Rank
Past performance	72	294	4.08	5	72	308	4.28	1
Technical staff experience	72	308	4.28	1	72	308	4.28	1
Experience in similar construction	72	305	4.24	2	72	306	4.25	3
Level of technology/technical ability	72	294	4.08	5	72	305	4.24	4
Quality assurance and control	72	302	4.19	4	72	304	4.22	5
Reputation of contractor	72	303	4.21	3	72	303	4.21	6
Tender price	72	282	3.92	10	72	297	4.13	7
Early completion period	72	286	4.00	8	72	287	4.00	8
Plant and equipment	72	290	4.03	7	72	285	3.96	9
Contractor's financial stability	72	283	3.93	9	72	284	3.94	10
Length of time in construction business	72	266	3.69	14	72	280	3.89	11
Contractor's managerial capability	72	282	3.92	10	72	277	3.85	12
Company image	72	268	3.72	13	72	271	3.76	13
Proposed construction methods	72	256	3.56	15	72	269	3.74	14
Safety records	72	269	3.74	12	72	266	3.69	15
Contractor registration category	72	236	3.28	17	72	264	3.67	16
Previous business relationship	72	232	3.22	19	72	257	3.57	17
Reference on contractor	72	235	3.26	18	72	241	3.35	18
Contractor-client previous relationship	72	242	3.36	16	72	236	3.28	19
Current workload	72	229	3.18	20	72	226	3.14	20
Previous records of claims and disputes	72	225	3.13	21	72	221	3.07	21
Contractor-consultants past relationship	72	210	2.92	22	72	213	2.96	22
Familiarity with project location	72	205	2.85	23	72	207	2.88	23
Contractor proximity to project location	72	203	2.82	24	72	191	2.65	24
Company nationality	72	192	2.62	25	72	189	2.63	25

1=Not considered, 2=rarely considered, 3=moderately considered, 4=highly considered, 5=most considered, N=Number of respondents, Score=Total score, RCI=Relative consideration index

Table 2 shows that the importance attached to the experience of contractors' technical staff, contractors' experience in the type of project to be procured, contractors' reputation and contractors' quality assurance and control rank 1st, 2nd, 3rd and 4th respectively. Contractors' technical capacity and performance in previous projects rank 5th while the plant and equipment possessed by contractors, the ability of contractors to complete projects before schedule and contractors' financial capacity rank 7th, 8th and 9th respectively in importance. Contractors' managerial capacity and tender price rank 10th while contractors' safety records, image and length of time in construction business rank 12th, 13th and 14th respectively. Contractors' construction methods, previous relationship with client, contractors' registration category, referees' comment, previous business relationship and current workload rank 15th, 16th, 17th, 18th, 19th and 20th respectively in importance. Contractors' previous records on claims and disputes, previous relationship with consultants, contractors' proximity to project location, familiarity with project location and nationality rank 21st, 22nd, 23rd, 24th and 25th respectively.

Extent of Consideration of Selected Criteria in Contractors' Selection

To evaluate the consideration accorded the selected criteria in the award of the contracts sampled, the extent to which the factors were considered by clients in selecting the contractors that executed the projects sampled was measured on a 5 point Likert-scale as described in the research methods. Respondents indicated the rank that represented their assessment of the consideration accorded each factor in the award of the contracts. The Relative Consideration Index (RCI) of each factor was analysed and presented in Table 2.

Table 2 shows that contractor past experience and technical staff experience rank 1st. Contractors' experience on the type of project to be procured, technical capacity, contractors' quality assurance and control, reputation and tender price rank 3rd, 4th, 5th, 6th and 7th respectively. Contractor's ability to complete projects before schedule, plant and equipment and financial capacity rank 8th, 9th and 10th respectively while contractor's length of time in construction, managerial capacity and image rank 11th, 12th and 13th respectively. Contractor's proposed construction methods, safety records and registration category rank 14th, 15th and 16th respectively while contractors' past business relationship, referees' comment and previous relationship with client rank 17th, 18th and 19th respectively. Contractors' current workload, previous records of claims and disputes and previous relationship with consultants rank 20th, 21st, and 22nd respectively while contractors' familiarity with project location, proximity to project location and nationality rank 23rd, 24th and 25th respectively.

Difference in Consideration of Contractors' Selection Criteria between Akwa Ibom and Cross River States

The study postulated a research hypothesis to compare the extent of consideration of the selected contractors' selection criteria in the projects sampled in the two states. The hypothesis states that the difference in the consideration of selected criteria for selecting contractors of projects located in Akwa Ibom and Cross River states is not significant. The hypothesis was tested using the Chi-square test with $p \leq 0.05$. The rule for the rejection of the hypothesis is that when the p–value>0.05, the test fails to reject the hypothesis but when the p–value≤0.05, the test rejects the hypothesis. The results are presented in Table 3.

Table 3 Chi-square test of difference in the extents to which selected criteria were considered for the selection of contractors of projects located in Akwa Ibom and Cross River states

Criteria	AIS		CRS		x^2	Df	p-value	Diff

N=Number of respondents, RCI=Relative consideration index, Df=Degree of freedom, Tech=Technical, S=Significant, NS=Not significant.

Table 3 reveals that the p-values for difference in the consideration of contractors' technical capacity, technical staff experience, reputation, ability to complete project before schedule, financial capacity, proposed construction methods, previous experience in construction business, safety performance, referees' comment, current workload, previous relationship with client, registration category and nationality for selecting contractors in the two states are greater than the critical p-value (0.05) therefore, the test fails to reject the hypothesis. The results indicate that the differences in the consideration of the thirteen factors for selecting contractors in the two states are insignificant. However, the p-values for differences in the consideration of contractors' quality assurance and control, past performance, experience in similar project, records of claims and dispute, plant and equipment, image, managerial capacity, familiarity with project location, previous business relationship, previous relationship with consultants and proximity to project location for selecting contractors in the two states are lower than the critical p-value (0.05) therefore, the test rejects the hypothesis. The results indicate that the consideration accorded the eleven factors in selecting contractors of projects located in the two states is significantly different.

DISCUSSION OF FINDINGS

The results of the relative importance of contractors' selection criteria have shown that contractors' technical staff, experience in similar construction, reputation, quality assurance and control, technical capacity, performance in previous projects, plant and equipment, ability to complete past projects on schedule, financial and managerial capacities rank higher than tender price and among the ten most important factors that affect contractors' selection. This result does not agree with the assertion by Jennings and Holt (1998), Fong and Choi (2000) and Egemen and Mohamed (2005) that tender price was considered the most dominant criterion. However, it agrees with the school of thought (Fong and Choi, 2000; Wong *et al,* 2001; Topcu, 2004; Egemen and Mohamed, 2005) that advocated the adoption of multi-criteria for contractors' selection. Incidentally, the respondents did not rate tender price very highly. Contractors-client and contractors-consultants relationships, contractors' registration category, current workload, previous records of claims and disputes, proximity and familiarity with project location and nationality rank among the ten least important criteria. These factors have little impact on quality or workmanship of contractors. The results may be explained by the fact that the two states where the study was conducted are striving to develop or procure world class infrastructures through contracting firms with highly experienced personnel. The fact that the two states are located in riverine areas and high revenue accrues to them from oil revenue may make cost not to be traded for quality.

The study also established that performance in previous projects is the most considered factor when selecting contractors. This result agrees with the assertion by Wong *et al.,* (2001) that the ability to complete projects on time is the most important criteria. Furthermore, contractors' technical staff, experience in similar construction, technology/technical ability, quality assurance and control and reputation are also highly considered above tender price in contractors' selection. There is ample evidence that these criteria are used for contractor selection in Nigeria. The Public Procurement Policy emphasised the use of the criteria and rated them as follows: contractor financial capability (15%), management capability (25%), experience in similar projects (20%), equipment and technology (20%) and annual turnover (5%) (Budget Monitoring and Price Intelligent Unit, 2005). Similarly, Aje *et al.* (2009) also discovered that contractors' technical, financial and managerial capabilities, past experience and health and safety records are the major criteria for evaluating the performance of contractors for civil engineering and building projects during prequalification and tender evaluation in Nigeria. Tender price is discovered to rank seventh in consideration implying that clients give higher consideration to price than the importance attached to it. However, the result tends to indicate that price is not the major criterion for contractors' selection. The results also reveal that contractors' workload, previous records of claims and disputes, relationship with clients and consultants, familiarity and proximity to project location and nationality which rank low in importance also rank low in consideration. This result implies that these factors do not have high effect on contractors' selection.

The test of the research hypothesis indicates that contractors' quality assurance and control, performance in previous projects, experience in similar construction, records of claims and disputes, plant and equipment, image, managerial capacity, previous business relationship and familiarity and proximity to project location are criteria whose consideration in contractors' selection in Akwa Ibom state is discovered to differ from that of Cross River state. This result tends to indicate that the consideration of these factors in contractors' selection in Nigeria is likely to vary from one state to another.

CONCLUSION

The study has examined the criteria for selecting contractors for the award of contracts in Akwa Ibom and Cross River States in Nigeria. This was achieved by conducting a survey. The results have established that first, a multi-criteria method is the approach adopted for contractors' selection in the two states that is several factors are considered by clients in the award of contracts to contractors. Second, the importance and consideration given to the criteria differ from one factor to another. The ten most considered criteria are contractors' technical capacity, staff experience, reputation, records of early completion of projects, financial capacity, quality assurance and control, past performance, proposed construction methods, experience in similar projects and construction business experience. Third, price is not the most considered factors in contractors' selection. The conclusion from these results is that contractors in the two states are not likely to be selected on the basis of lowest tender. Furthermore, the most considered factors are those that concern the performance of contractors rather than his price. The implication of the result is that clients in these two states are likely to give more consideration to issues relating to contractor's performance than his price in their selection. From the conclusion, it is recommended that while contractors that operate in the two states strive to be competitive in their bids, they should ensure that issues that can enhance their performance such as

technical staff capacity, financial and managerial capacities and quality assurance and control are not compromised but given more attention than price. The success of their bids is better enhanced by these factors than by price.

FACTORS CONTRIBUTING TO UNSUCCESSFUL HOUSING ASSOCIATION PARTNERING ARRANGEMENTS

David Liguori[1], Prof James Sommerville[2] and Dr David Manase[3]

[1,2,3] *School of Engineering and the Built Environment, Glasgow Caledonian University, Glasgow, G4 0BA, United Kingdom*

ABSTRACT

The challenging economic conditions have forced a reduction of investment into social housing projects in the UK. Housing Associations are therefore striving to minimise waste and optimise value for money. Partnering has been advocated for many years, with Housing Associations subscribing to this procurement method. The success of a partnering arrangement can be significantly impacted by the inadvertent inclusion of factors that inhibit the mechanisms of the partnering ethos. A thorough review of the industry perceived factors that contribute to unsuccessful partnering arrangements has been undertaken in this study. This will enable an empirical assessment of the level of importance placed specifically by Housing Associations on the reviewed factors in future research and in the process contributes to a conceptual model for effective Housing Association partnering arrangements. It is envisaged that this research, upon which this research is based, will assist Housing Associations avoid unsuccessful partnering arrangements through gaining an understanding of the factors that must not be inadvertently translated into a project. The findings provide an evaluation of the barriers that contribute to unsuccessful partnering and highlight the Housing Association characteristics that could exacerbate ineffective partnering.

Keywords: Factors, Housing Associations, partnering, procurement.

INTRODUCTION

Housing Associations were formed to provide quality and affordable rented housing. Housing Associations and co-operatives own and manage approximately 47% of Scotland`s affordable social housing stock. The indicative value of Scottish Housing Association assets is approximately £7.6 billion. Delivering socially owned rented housing is an important function within society. Gibb and Leishman (2011) emphasised the reduced funding available for new build social housing. The former Housing Minister in Scotland, Alex Neil Scottish Government (2010), highlighted to Housing Associations that achieving value for money was an essential element to underpin the future investment programme in housing. In recent times, partnering has

[1] David.liguori@gcu.ac.uk
[2] J.sommerville@gcu.ac.uk
[3] David.manase@gcu.ac.uk

been advocated as one of the preferred procurement methods for new build and maintenance works commissioned by Housing Associations.

Housing Associations are private organisations however, they are still non-profit bodies who are regulated rigorously by the government. A substantial amount of funding for constructing new dwellings comes from grants provided by the government. These characteristics differentiate Housing Associations clients from their private sector counterparts. A consequence of the thorough regulation is the requirement to demonstrate competitiveness. Fisher and Green (2001) highlighted that if partnering is to be followed, then those charged with public spending need to be equipped with appropriate tools to identify and provide sanctions to protect against anti-competitive behaviour that can result from partnering agreements. Another perceived differing characteristic is that procedures implemented by the public sector can often work against the mutual trust and open relationship, which forms the prerequisite of partnering (Woodrich, 1993). Funding mechanisms also differ between Housing Associations and private sector clients, as tenants' rent and government grants are the drivers for investing in maintenance and new build. Another significant difference is that Housing Associations are not-for-profit bodies, who are committed to providing low cost social housing, as opposed to private sector organisations that may primarily focus on profit. Housing Associations may also be prevented to include within the arrangement a provision to share savings with the contractor (Housing Forum, 2000). According to Burnes and Coram (1999), another barrier is the risk-aversive nature of public sector organisations that is embedded within the ethos.

Despite these inherent characteristics, Housing Associations have been encouraged for some time to utilise partnering arrangements as the preferred procurement method for delivering construction and maintenance projects. The Housing Forum (2002) encouraged Housing Associations to embrace partnering via long term strategic supply chain alliances. The success of partnering is significantly dependent on specific barriers not manifesting into the arrangement. Eriksson et al. (2008) noted that increasing the awareness of the barriers that compromise the success of the partnering arrangement is vitally important. A plethora of research has been conducted to identify the barriers that impact the success of a partnering arrangement within the construction industry generally. There is however limited literature available that focuses on the perceived barriers considered by specific client groups. The characteristics that differentiate Housing Associations from other clients highlight the importance of focussing exclusively on their needs. This research will therefore assess the importance placed on the identified partnering barriers from the sole perspective of Housing Associations. Unveiling the fundamental partnering barriers for Housing Associations will provide guidance on effective partnering and subsequently mitigate the risk of an unsuccessful partnering arrangement, through identifying the barriers relevant specifically to Housing Associations. This could subsequently increase the probability of achieving value for money. Furthermore, the effective utilisation of capital could enable more maintenance and construction projects being commissioned and therefore ease the effects of reductions in investment.

 ISBN: 978-1-84219-840-7 .

METHODOLOGY

This stage of the research has been conducted on the basis of an extensive review of the existing literature, based on the general construction industry. Naoum (2007) identified that a literature review attempts to integrate what others have done and said, and criticise previously scholarly works, to build bridges between related topic areas, and/or identify the central issues in a field. The review of literature focuses on the perceived barriers contributing to unsuccessful partnering arrangements. The identified barriers will form an element of a conceptual model for Housing Association partnering. The appropriateness of the reviewed barriers from this stage of the research will be assessed in subsequent fieldwork. Understanding the necessary barriers to be avoided in Housing Association partnering arrangements could mitigate the likelihood of unsuccessful partnering arrangements.

BARRIERS OF PARTNERING

The literature contains a substantial volume of barriers that compromise the success of a partnering arrangement. The following barriers are based on the construction industry generally, without focus on a specific client group. The validity and appropriateness of these barriers will be tested in subsequent research, within a focussed Housing Association context.

Lack of continuous evaluation and improvement

Good practice dictates that the contractor should not be the only responsible party for continuous improvement, as both the client and contractor should work together to maximise the effectiveness of a project. Continuous improvement was identified by Ng *et al*., (2002) as a crucial factor required for a successful partnering project, as it enabled the monitoring of the mutual objectives set by partners, prior to commencing the project. Chan *et al*., (2003) further highlighted that frequent barriers associated with a lack of continuous improvement were approval times and development costs. This is a significant feature of partnering to assess the outcome of implemented arrangements. Housing Associations must ensure that monitoring processes are established to measure performance. Housing Associations must invest resources to ensure the appropriate monitoring techniques are set up and utilised throughout the duration of the project.

Cultural barriers

The culture of partnering agreements embraces the ideology of operating within a spirit of mutual trust and cooperation, advocating a win-win attitude between parties. Ng *et al*., (2002) believed that cultures characterised by conservatism and inflexibility are vital barriers to partnering since as there are limited compromises and team work solutions to action arising problematic issues. Research conducted by Eriksson *et al*., (2008) conclusively identified cultural barriers as crucial to the transition to increasing the level of cooperative relationships between parties. Cultural barriers will be extremely difficult for Housing Associations to surpass. The non-profit nature and need to demonstrate competition by Housing Associations could make it difficult to destroy cultural barriers. However, the construction industry has used traditional and adversarial methods for many years, with many clients continuing to use traditional methods as it is well understood and can provide positive results.

Uneven commitment to mutual objectives

For a partnering project to be successful there is a fundamental requirement for commitment between the stakeholders. A partnering agreement should not be entered unless partners fully commit to the agreement. Research conducted by Akintoye *et al*., (2000) assessed the barriers associated with implementing supply chain partnerships. The research assessed the contractors' perception, and concluded that the most important barrier was a lack of top management commitment. Housing Associations may however find it difficult to fully commit to a partnering arrangement. An example of this could be sharing any cost savings with the contracting partner. A Housing Association could find it difficult to pass any savings back to the contractor, as any savings could be reinvested into more development of properties or upgrading. Housing Associations are non-profit organisations, therefore would seek to reinvest.

Non-inclusion of sub-contractors and suppliers

Partnering arrangements do not only involve the client and main contractor. The majority of works are undertaken by sub-contractors and suppliers. Jones and O`Brien (2003) highlighted that many sub-contractors are small to medium enterprises, and lack the knowledge, expertise and resources to improve performance, without guidance and encouragement from the client and main contractors. The failure to include sub-contractors and suppliers into the partnering arrangement, could result in the theoretical benefits of partnering not being achieved. Including the sub-contractors and suppliers could result in potential cost savings through providing continuity of work over a period of time. The quality could also increase as the sub-contractors and suppliers are fully aware of the client objectives. Housing Associations should incorporate sub-contractors and suppliers when possible, to optimise best value.

Misunderstanding of partnering concept

The ethos of partnering represents a significant divergence from the underpinning philosophies of traditional contracting, which can produce a more adversarial and fragmented nature between the client and contractor. Chan *et al*., (2003) suggested that a thorough knowledge and understanding of the concept of partnering agreements is crucial to form a successful partnering project, therefore if the partners misunderstand the partnering concept, the implementation of the partnering project will be problematic. The research conducted by Akintoye (2000) highlighted that a poor understanding of the partnering concept was the second most important barrier, perceived by contractors, which could result in an unsuccessful partnering agreement. An understanding of partnering appears important, however Housing Associations must be prepared to expend resources on staff training to ensure a comprehensive understanding, prior to initiation of the implementation phase. This could prove decisive and could ultimately dictate the level of value for money that is achieved by the Housing Association.

Discreditable relationship

Partnering arrangements are perceived as providing many positive features for the construction industry, such as more efficient performance, effective communication between parties and more trust between the parties. There is a degree of caution however conveyed by practitioners, as Newman (2000) suggested that the open and trusting relationship between partners, could be abused and perceived as corruption. The reputation of Housing Associations is important, therefore any allegations of corruption could result in a loss of trust of trust from tenants and the Scottish Government taking action to investigate. To counteract this possibility, Longstaff

(2000) suggested employing an independent ethics audit, to create transparency of a partner's ethics and principles. This may be advisable for Housing Associations to protect their reputation, however, would result in further costs associated with implementing the partnering arrangement.

Insufficient effort to keep partnering going

A partnering agreement is not effective upon signing a partnering charter. There is an important requirement for partners to continually work. Larson and Drexler (1997) intimated that partnering agreements could cost parties to ensure an effective alignment of organisations throughout a partnering agreement. In agreement, Chan *et al*., (2003) highlighted that a partnering agreement may require additional staff, resources and time. Housing Associations must carefully forecast the cost of entering a partnering arrangement. The cost of additional staff, resources, time and training must be assessed to identify the feasibility of implementing a partnering arrangement. With extremely low prices being submitted by contractors during the difficult economic climate, Housing Associations may not be able to resist procuring projects on a traditional basis to capitalise on the low prices. The costs to implement and sustain a partnering arrangement could push Housing Associations into utilising traditional procurement.

Inefficient problem solving

Partnering projects that are not effectively implemented, can inadvertently promote the neglect of arising problematic issues, which can escalate, thus compromising the outcome of a project. An empirical study conducted by Ng *et al*., (2002) highlighted that a factor which can result in an unsuccessful partnering project was the neglect of arising issues, which were not rectified at the fruition point, therefore escalated, causing negative outcomes. This could be viewed as a deeper problem, as an effective partnering arrangement should not allow arising issues to escalate, therefore other aspects of the partnering relationship must be failing. The failure to address problematic issues was supported by Chan *et al*., (2003) suggesting that within a partnering project, very often, issues and problems are allowed to slide and escalate. Housing Associations must ensure that arising problematic issues are addressed as quickly as possible to mitigate the escalation of the issue, thus should not compromise the overall success of the project.

Lack of trust and relationship problems

The inclusion of trust is widely recognised as an essential pre requisite of partnering. Akintoye *et al*., (2000) identified trust as the most important factor associated with a successful partnering project. The risk associated with Housing Associations developing trust for the contracting partner is however necessary. The partnering arrangement will not work unless both parties make the effort to trust each other. Albanese (1994) argued that the project environment conducive to trust may be affected by bitter experience in litigation, dispute, and past adversarial relationships. Previous unsuccessful partnering experiences that a Housing Association or contracting partner may have encountered can be remembered and learned from, however cannot be continually referred to within a new partnering arrangement

Lack of continuous open communication

The concept of partnering advocates the continual sharing of information between partners, in an open, honest and timely manner, throughout the duration of a project. Research conducted by Black *et al*., (2000) highlighted that effective communication

was one of the most important factors associated with a successful partnering project. Communication between parties involved in a partnering agreement must be effective, as the needs and expectations of each partner must be clearly understood and recognised. Further research carried out by Ng *et al*., (2002) concurred, highlighting that a lack of open and honest communication facilitated a win-lose attitude, contradicting the partnering ethos. Housing Associations must ensure that effective communication is present within a partnering project, through an open, honest and timely manner, to increase the probability of a successful partnering arrangement.

DISCUSSION

The review of literature highlights an array of barriers that contribute to unsuccessful partnering that are applicable to the general construction industry. This will enable an empirical assessment of the level of importance placed specifically by Housing Associations on the reviewed factors in future research. Barriers such as lack of mutual trust and the failure to effectively communicate appear to be fundamental elements of a partnering arrangement. The critical analysis of the literature did highlight other barriers that could manifest into Housing Association partnering arrangements induced by their defining characteristics. Cultural barriers may be difficult for Housing Associations to resist. Fisher and Green (2001) highlighted that protecting taxpayers from anti-competitiveness in partnering was essential. The non-profit structure and need to demonstrate competition to tenants could make it difficult for Housing Associations to destroy cultural barriers. Housing Associations may also struggle to fully commit to partnering and share risk as according to Burnes and Coram (1999), there is an inherent risk-averse philosophy within public sector organisations, which also applies to quasi-public sector bodies. Another barrier that could impact Housing Association partnering arrangements is uneven commitment to mutual objectives as the current economic conditions and reduced investment from the government (Gibb and Leishman, 2011), may shift Housing Associations priorities and mind set to focus more on their own objectives. The current reduction in investment from the government may also result in Housing Associations not dedicating full effort in keeping the partnering arrangement going as they may be unable to commit the required level of resources to ensure the partnering arrangement is set up and appropriately monitored for a series of projects. The process that could result in unsuccessful partnering for Housing Association is illustrated in Figure 1. The level of importance placed by Housing Associations will be ascertained in subsequent research and will contribute to a conceptual model for effective Housing Association partnering arrangements.

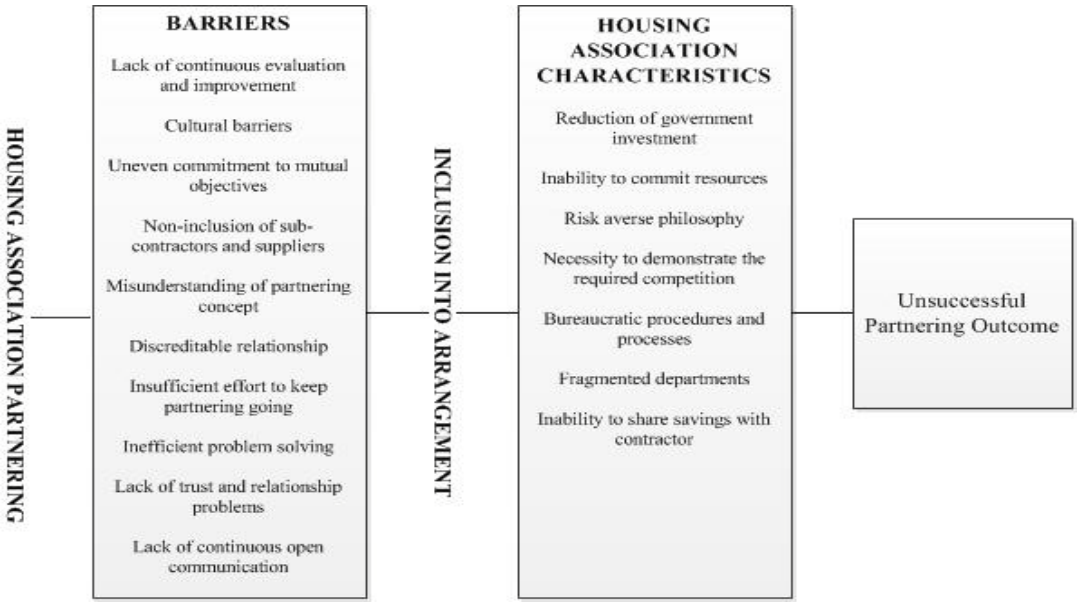

Figure 1 – Housing Association barriers and potential outcome

The evaluation of barriers that contribute to unsuccessful partnering was based on literature associated with construction partnering generally as there is limited literature that focuses on specifically Housing Association partnering arrangements. The factors that differentiate Housing Association clients from private sector clients (Woodrich, 1993; Burnes and Coram, 1999; Housing Forum, 2000; Fisher and Green, 2001), highlights the necessity to establish the essential barriers of partnering for solely Housing Associations. There may be an argument however that these differing characteristics of Housing Association clients could prevent partnering from effectively functioning. The reviewed barriers could compromise the success of a partnering arrangement. It is therefore important that the Housing Association barriers contributing to unsuccessful partnering are identified and avoided to increase the probability of obtaining value for money. The research will address any divergence, in terms of importance between the literature and the view of Housing Associations.

CONCLUSION

Evaluating the literature has identified the barriers that compromise effective partnering. The plethora of previous research lacks focus on specific client groups therefore there was minimal correlation, within the literature, between the barriers and Housing Associations. The reviewed characteristics that distinguish Housing Associations from private sector clients, emphasis the need to differentiate between the most and least important factors that contribute to unsuccessful Housing Association partnering arrangements Understanding these barriers within the context of exclusively Housing Associations, can assist in mitigating the risk of unsuccessful partnering arrangements through identifying the barriers that must be avoided. This will assist the achievement of better value through more effective utilisation of capital invested in construction and maintenance Housing Association projects. The reviewed barriers will be assessed in terms of important in the subsequent research to be conducted to provide guidance to Housing Associations when entering into a partnering arrangement.

ABSTRACT

Outsourcing has become increasingly important in both the public and private sectors due to its potential to reduce cost and increase efficiency by taking advantage of expertise and economies of scale of specialized vendors. Yet many challenges also exist in managing and implementing outsourced agreements. Included among outsourcing challenges are contractual hazards, poor baseline benchmarks, vendor opportunism, and vendor dependence. Much research has focused on the capability of the external outsourced vendor, while there is less research into the procurement and management processes of the client organization and what role they should adopt within the outsourcing agreement. A case study approach has been adopted to observe and document the outsourcing of a large scale services contract at a public organization via the Best Value Model. Data collection consisted of observations throughout the procurement, planning, and management process with access to the documentation and communication between client and vendor, particularly regarding performance metrics. Lessons learned from this successful outsourcing case are presented to provide a framework for managers and client organizations. This approach and framework has potential to improve outsourcing results. Future testing and continued longitudinal studies are recommended.

Key Words: best value, performance measurement, preplanning, procurement, outsourcing

INTRODUCTION AND LITERATURE

The term outsourcing was first introduced in the 1960s and 1970s in the realm of equipment manufacturing (Corbett, 2004). In the current marketplace, companies outsource a virtually boundless variety of products and services, from cleaning to catering to business processes to information technology management (Engardio et al., 2006). The growing trend of outsourcing stems from the common belief that specialized private companies can assist other organizations to save money and improve efficiency in the client's non-core tasks by utilizing their expertise to perform services faster and cheaper (Russell 2010).

[2] bclines1@mainex1.asu.edu
[3] kenneth.sullivan@asu.edu
[4] dean.kashiwagi@asu.edu

The need to foster successful outsourcing relationships has become critical, and much research has been focused on the client outsourcer's perspective of identifying the outsourced vendor's capabilities (Perunovic *et al*., 2012). This has resulted in claims that vendor capabilities are one of the most important factors in the success of outsourcing (Levina and Ross, 2003). Sako (2010) called for more research to explore what client organizations need to consider in order to make the outsource relationship a success. The process and role of the client organization in aligning with external vendors has been subject to less research, a topic this paper will explore in more detail to develop a framework of practices for the outsourcing organization to undertake to improve outsourcing success. A case study approach was utilized to examine the outsourcing process undertaken to procure, plan, and deliver a large scale services contract within a public organization. Based on lessons learned and contract results, a framework of management practices is proposed to assist outsourcing efforts.

Benefits of Outsourcing

When managed correctly, outsourcing can achieve greater efficiencies, improved service performance levels, and reduced costs (Davis, 2005). Studies show that the mechanism by which outsourcing can allow organizations reduce costs is through process standardization and economies of scale (McIvor *et al.*, 2011). A recent study by Accenture confirmed that almost half of the businesses surveyed have found outsourcing to be the leading supply chain reform that saves costs ("IT Spending Still Strong," 2001). Many public organizations have turned to Privatization Task Forces to review opportunities within state and local government. Cost savings in the hundreds of millions of dollars have been reported via outsourcing in the states of New Jersey and Pennsylvania as well as the City of Chicago (Russell, 2010).

Challenges of Outsourcing

Outsourcing does bring certain challenges. The risks most commonly associated with outsourcing include: contractual hazards, excessive dependence on a single vendor, knowledge loss, performance measurement difficulties, and vendor opportunism (Currie *et al*., 2008; Handley and Benton Jr., 2012, Feeny *et al.*, 2005). Benchmarking is critical to establish a base line level of services to show the client organization how good they are at running services internally, yet it is often difficult to accomplish or is ignored (McIvor *et al.*, 2011). In fact, most outsourcing organizations do not have metrics in place before they decide to outsource a service. "The problem is that outsourcing deals are really about risk," says Adam Strichman, co-founder of Sanda Partners, an outsourcing consultancy. "You're taking the risk of the unknown and dumping that on your supplier," he says. "You're outsourcing a problem to a company that has limited control over the root cause of the problem." (Russell 2010).
These challenges make the role of business and procurement professionals a key factor of success in managing and implementing outsourced (Dickens Johnson, 2008).

RESEARCH DESIGN

A case study approach was selected for this research study to observe and document results in the outsourcing of a large scale services contract in a public organization. The case study method was selected because it enables greater access to data and enables researchers to analyze relationships and management processes. The researchers applied a longitudinal approach with the outsourced contract being

analyzed for a period of more than two years. Researcher involvement began more than a year prior to the contract being signed, which provided significant involvement and insight into the procurement and planning of the outsourced agreement. The researchers participated in the agreement directly as educators to assist the client in implementing the Best Value Model (Kashiwagi, 2012), a value and risk based procurement system and implementing a formal preplanning process *prior to* finalizing and signing the contract. The researchers also aided with establishing performance measurements to define the baseline proposal and monitor service levels during the first year of the contract.

The outsourcing organization in this case study, Arizona State University (ASU), was selected for multiple reasons. Preliminary discussions with management and key personnel revealed the complexities and challenges in moving towards an outsourced solution and establishing a successful agreement. The topic of outsourcing – book store services at all four ASU campuses – represented a large scale contract in a complex and rapidly evolving industry that has been increasingly impacted by technology in the form of online textbooks, rental texts, e-books, and social media marketing strategies. Involvement in such a complicated project was anticipated to result in important insights and learning that would help develop a framework for successful outsourcing practices. Furthermore, the research team already had strong relationships with ASU, which enabled greater involvement in the project. This made it possible to gain access to key personnel who were involved in the project from initial formulation to full implementation. This perspective enabled performance level comparisons between the original status quo service operation and the resultant value delivered in the outsourced agreement.

The primary source of data collection was via access to the documentation and communication between client and proposing vendors during the procurement process. Data sources included Request for Information (RFI), baseline performance metrics, Request for Proposals (RFP), Vendor Submittals and Financial Proposals, Selection results, and preplanning documentation. The research team analyzed the data to determine the optimal outsourcing arrangement and to determine common factors and key lessons learned to develop a framework. Follow-up data collection and analysis occurred after the first full school year of book store operations to understand the level of service delivered.

CASE STUDY BACKGROUND

Prior to outsourcing, the client organization operated and managed all book store services internally. ASU directly owned the book stores on campus and all sales revenues were directly re-circulated within the university. Due the large size of the university, ASU has four separate campus locations within the Phoenix metropolitan area, each of which is home to its own book store. Although ASU was satisfied with their current book store operations, the rapidly changing landscape of the book store industry created motivation to seek an understanding of current market capabilities to deliver increased value. ASU determined to investigate outsourcing options to compare against their status quo operations. The intent was to identify a company with the expertise to be a leader in the book store management field and offer a best practices approach to implementation and delivery for years to come.

PROCUREMENT AND PLANNING OF OUTSOURCED AGREEMENT

A major challenge for the client in procuring book store services was an incomplete understanding of what information to provide to prospective vendors. The client determined that comprehensive and accurate proposals were deemed necessary to ensure project success. Yet, as is commonplace during the initial stages of the outsourcing process, the client desired world-class service levels but was unsure of how to achieve this result. To address this issue, the client's first step was to solicit a Request for Information in order to find out what information vendors required to be able to propose in an effective manner. The result was a wealth of information requested by the prospective vendors which the client then included within the scope of services for their Request for Proposal. The RFI information requested by vendors included current financial information, existing sales policies, technology sales arrangements, current and projected sales volumes, commission structures, personnel information, facility conditions, capital investment plans, other external factors and initiatives that may impact future service levels. These metrics helped the client formulate a detailed and informative scope of work that ultimately resulted in accurate proposals and became the first attempt to align baseline performance measurements.

During the RFP process, the client incorporated principles of the Best Value Procurement Model by making the assumption that each vendor had the expertise to provide book store services that fulfilled the minimal needs. Instead of focusing on this minimum expectation, the client allowed the vendors to compete based on value and their ability to maximize the client's satisfaction. The submitted proposals were asked to be brief, show differentiation, and allow ASU to make a data-based decision on which firm is the best value vendor for the client.

The RFI process not only enabled the client to develop an accurate scope, but also resulted in recommendations of various service options that the vendors could propose on. The resultant RFP was composed of three financial proposal options: the first two were defined by the client and had differing potential conditions regarding financial structures and personnel requirements. The third option was left completely open to the proposing vendors to develop the most advantageous cost proposal according to their preferences and expertise. This was consistent with core philosophies of the Best Value Model, which strives to minimize risk by better allocating project risk and responsibility to expert vendors. This third option, which was essentially a "vendor-generated solution," was ultimately the option accepted by the client to partner with the selected vendor. Although interesting, it may not be completely surprising that the vendor-generated solution was the most advantageous, since the whole point of outsourcing is to align experts to deliver a service that is a non-core activity for the client.

Structured Preplanning for Outsourcing Transition and Operation

The selected vendor was then brought forward into the Best Value Clarification Period, which is a formal preplanning process that occurs prior to the final award being made. This is different from more traditional procurement functions, where the procurement process narrows the selection to one vendor and then directly enters into a contract. In the Best Value process the potential vendor is asked to clarify their

proposal and the metrics and measurements become part of the contract, which was found to be extremely valuable in an outsourcing scenario.

The Best Value preplanning process centered on clarifying the proposal, addressing client concerns, establishing a transition schedule, finalizing service baseline numbers and future projections, and establishing performance measurements to track service levels during execution. The selected vendor entered the preplanning process with a detailed plan and immediately engaged the client in discussions about the transition schedule to set up and commence outsourced services. These topics not only served as further demonstration of the vendor's ability to accomplish the job, but also resulted in further clarification of the client's baseline performance metrics of their current and past levels of service as provided internally. Based on this information, the vendor identified the original commencement date of services, as dictated by the client, to be a significant risk. The vendor instead proposed moving the original start date to occur before the beginning of the next semester. The client yielded to their expertise, assisted in providing all needed information to make the transition seamless, and ultimately the book store opened up on schedule.

RESULTS AND DISCUSSION

The application of the Best Value Model to outsourcing a large scale services contract was found to be highly successful. The first major success came from the RFI process which aided the client organization in understanding how to develop a scope of services that detailed enough to enable outside vendors to (1) understand the current benchmark of performance within the client organization, (2) craft a financial proposal that was optimal for both partnering organizations, and (3) identify existing opportunities for improvement. This was advantageous to project success because it saved considerable time during the transition phase where the client went from running all book store services in-house to releasing full control and management of operations to the outsourced vendor.

Coupling the Best Value procurement and preplanning processes had a significant beneficial impact on achieving a smooth transition to outsourced services. The vendor was able to enter the client's environment, clarify necessary details, present their plan to client managers and personnel, and then transition into full operations before the start of the next semester, which was a critical milestone date. In fact, the process was so successful that zero percent transition delays were encountered, which was remarkable for such a large scale outsourcing across four separate campuses.

After the first year of operations, the outsourced contract model was a documented success. Not only did the contract deliver significant monetary value to both client and vendor (while simultaneously eliminating client management responsibilities), but end users also felt the impact of increased service levels the expert vendor was able to maintain. As a part of their performance measures, the vendor ran numerous customer service surveys and compared results against their company-wide benchmark of 88 percent customer satisfaction. Annual results showed an average level of customer satisfaction to be nearly 93 percent across all four campuses, which was nearly a full five percent improvement over the established benchmark. Full results are shown in Table 1.

 ISBN: 978-1-84219-840-7 .

Table 1: Increased Customer Satisfaction with Outsourced Book Store Services

Service Area	Customer Satisfaction	Improvement over Company Benchmark
Campus 1	94.9%	+ 6.9%
Campus 2	96.3%	+ 8.3%
Campus 3	91.6%	+ 3.6%
Campus 4	89.1%	+ 1.1%
Average	92.97%	+ 4.97%

Framework for Outsourcing

Lessons learned from the success of the presented case study have resulted in a framework of key outsourcing practices for clients and managers to consider before beginning the outsourcing process.

Engage the vendor community to develop potential service level agreement options.

Providing a clearly defined proposal and established project objectives is critically important to gain proper alignment of parties in an outsourced agreement. Since the vendor community has greater expertise in the specific field in question, they may also have a better understanding of the required details and potential agreement options that will maximize success. Engaging with potential vendors will enable the client to gain ideas, explore various sourcing options, and create an accurate scope. Utilizing a Request for Information was shown to be highly successful to help the outsourcing organization to develop a detailed and accurate scope of services, which enabled responding vendors to provide accurate costing and delivery plans.

Align expertise via vendor-generated solutions.

Clients may benefit from including a vendor-generated solution option within their Request for Proposal. This practice allows full freedom for vendors to utilize their expertise and propose the most advantageous agreement possible. Benefits may be realized due to innovative financial structures or by improved performance propositions.

Measure the client organization's baseline performance.

A critical part of outsourcing is to accurately define the current level of performance within the client organization. Not only does this help create more effective proposal responses, it also provides greater potential for project success by facilitating more effective planning efforts to minimize transition delays and optimize long term performance. Vendor involvement may be necessary to determine what specific measurements are needed, and several iterations may occur before the full baseline performance metrics are established. In the presented case study, the types of baseline metrics required were uncovered via vendor feedback to a Request for Information, actual measurements were presented n the Request for Proposal, and the final current baseline metrics were clarified within the preplanning process. Performance metrics that should be considered include:

- Current financial structures (commissions, profit margins, etc).
- Existing sales and service policies.
- Current and forecasted service levels and volumes.
- Existing facility conditions, capital investment plans, technological support.

- Personnel, staffing, and benefits.
- Specialties and external conditions within the client's environment that may impact the service level or execution.

CONCLUSION

The option of outsourcing non-core business functions to external vendors has the potential to add significant value to client organizations. Yet procuring, establishing, and maintaining a successful outsourcing relationship has long been met with a series of challenges and oftentimes both parties – the client and outsourced vendor – are left frustrated or unsatisfied with less than optimal results. This paper aims to provide a framework of advantageous practices to aid client organizations that may seek an outsourcing effort. A case study of a successful outsourcing arrangement was presented, the process utilized was discussed, and resulting performance levels shown. The success of the Best Value Model has the potential to be useful in outsourcing large scale service contract. Further testing of the model is needed as well as long-term measurement (longitudinal studies over a period of years) of outsourcing success on individual contracts such as the presented book store case.

ABSTRACT

Maintaining competitiveness by increasing performance is an ever-present goal in the construction industry, yet project performance has remained relatively stagnant and schedule slippages and cost overruns continue to plague the construction stage. A growing sentiment exists that these problems may be best addressed before the construction phase commences, prompting investigation into improved pre-construction and project planning approaches. The best value business model incorporates a formal preplanning process that has been tested recently in the construction industry and has been documented to produce favourable results. The best value planning process is based on four primary methods: (1) project planning is done before signing the contract; (2) identification and alignment of expertise; (3) transference of project responsibility and accountability to the contractor; and (4) emphasis on planning supply-chain interactions rather than technical aspects. Lessons learned are shared from implementing this process at the University of Alberta on a high profile $21 million design build project for a high tech research facility. Significant cost savings, minimized schedule impacts, and optimized coordination of the construction stage were documented. Case study results are encouraging and suggest that this pre-contract planningapproach may be a viable consideration in the construction industry.

Keywords: alignment, best value, planning, preconstruction, risk management.

INTRODUCTION

Effective planning leads to enhanced project performance, resulting in benefits such as cost and time savings, clear scope definitions, and the reduced occurrence of change orders (Gibson *et al.*, 2006; Haponova and Al-Jibouri, 2009; Yates and Eskander, 2002). Shapira *et al.* (1994) defined planning as "the process of deciding what to do and how to do it before action is required." Verheij and Augenbroe (2006) treated project planning as the coordination of interconnected "dialogues" or decisions between project partners that are established into a formal plan. Research has linked poor planning to delays, cost overruns, and owner dissatisfaction (Casinelli, 2005).

[1] kenneth.sullivan@asu.edu
[2] bclines1@mainex.asu.edu

Contractors and project owners alike are significantly impacted by such occurrences (Ndekugri *et al.*, 2008). Numerous reports and research studies indicate that the majority of construction projects experience delays, oftentimes a direct result of poor project planning (HMSO, 1995; OGC, 2003; Casinelli, 2005). Gibson *et al.* (2006) noted that many organizations lack the expertise or the drive to thoroughly perform preplanning tasks.

LITERATURE

Preplanning activities occur at various stages in the project lifecycle, wherein the planning processes in each stage are comprised of different goals, stakeholders, degrees of certainty, and levels of detail. Distinct planning processes typically occur at four different periods in the project life cycle: Preproject, prebid, preconstruction, and during-construction.

Preproject Planning is the initial planning process undertaken by the project owner, designer, and consultants. Activities include all tasks between project initiation and the beginning of detailed design (Gibson *et al.*, 2006). Chang *et al.* (2010) found coordination issues between contractor and design as the main problem hindering performance in this stage.

Prebid Planning is primarily a contractor activity to plan general actions in project execution and takes place prior to bid submission.

Preconstruction Planning expands from when a single contractor is selected or awarded the bid up until a certain point within the construction process. This stage traditionally occurs at no more than one month before mobilization and no more than two additional months beyond mobilization (Laufer *et al.*, 1994).

During-construction Planning consists of all activities beyond mobilization and completion of preconstruction planning.

This research presents a unique preplanning model that occurs prior a contract being signed between the owner and contractor. The planning process transpires post selection and before mobilization, which relates closest with the traditional method of preconstruction planning. This paper focuses on the preconstruction stage of the project lifecycle (however, the presented preplanning model is recommended to be linked with prebid planning and extend into during-construction planning). Preconstruction deliverables traditionally include a detailed front-end schedule, baseline milestone schedule, risk management process, operational work plan, and a clear scope (Casinelli, 2005; Hassanein, 2005; Laufer *et al.*, 1994).

The presented planning model is process-oriented and emphasizes coordination between the various project stakeholders. A process-oriented planning process is recommended by numerous research studies, mainly due to the importance of addressing project team alignment (Haponava and Al-Jibouri, 2009; Hastak *et al*., 2008, Griffith and Gibson, 2001). Alignment, which is recognized by the Construction Industry Institute as a best practice for project planning, leads to heightened project performance and is defined as “the condition where appropriate project participants are working within acceptable tolerances to develop and meet a uniformly defined and understood set of project objectives” (CII, 1997). One reason that alignment is so important is stated by Haponava and Al-Jibouri (2009), whose research showed that contractors unanimously agreed that clients are on different levels prior to beginning the construction process. Defining the client’s environment

and managing their requirements becomes critical to align the different levels present on a project. A research study of seven construction project case studies identified alignment as the most frequently employed CII best practice that was responsible for radically reducing project cycle times by greater than 25 percent (Hastak *et al.,* 2008).

BEST VALUE PREPLANNING MODEL

The Best Value Model is an owner-driven, quality-based system of contract procurement and execution, and includes models for Procurement, Preplanning, and Contract Management (Sullivan *et al i.,* 2009). The Best Value Preplanning Model is a process-oriented methodology that transpires prior to contract execution. The Best Value Preplanning Model is owner-facilitated, contractor-driven, and aims to establish a complete project plan before project work begins. This model was originally developed at the Performance Based Studies Research Group (PBSRG) at Arizona State University (ASU) and has been tested on more than 900 projects totalling more than $4.7 billion in procured services and construction. In construction, the preplanning methodology has been tested on capital projects and renovations, over a wide range of scope requirements, and within multiple delivery systems (including design build, construction manager at risk, and integrated project delivery with value-based selection). PBSRG has assisted many owners in the public and private sectors to implement the Best Value Preplanning Model, including the University of Minnesota, Rochester Public Schools, Idaho Transportation Department, State of Alaska, State of Washington, University of New Mexico, U.S. General Services Administration, City of Peoria, and University of Alberta.

Improving Planning Impact Through Alignment and Transfer of Risk

The construction industry has had a difficult time in standardizing preplanning processes due to highly diverse deliverables. Furthermore, owners have difficulty differentiating contractors based on quality and value, which has resulted in selection methodologies that predominantly consider price (Sturts and Griffis, 2005). The price-based market has placed greater significance on non-value adding activities, such as increased owner management, inspection, and quality control (Seppala, 2004). The Best Value Preplanning Model aims to improve project performance by aligning all stakeholders within the construction project team utilizing the following methods:

Pre-Contract Planning. The timing of the Best Value Preplanning Model is unique when compared with traditional industry practices in that it occurs prior to signing the contract. The planning process begins following the procurement selection a single contractor, who is then brought forward into a pre-contract planning relationship. The selected contractor is responsible for establishing a full project execution plan, coordinating with owner stakeholders, generating a clear scope definition, establishing a full project milestone schedule, documenting a risk management plan, and receiving owner signoff on all functional plans prior to the contract.

Project Level Role Reversal. The current price-based market has seen owner decision making, inspection, and management increasingly drive project activities, yet the idea of the owner hiring a contractor for their expertise and then directing them how to operate inherently lowers efficiency (Sullivan, 2011). The Best Value Preplanning Model seeks to minimize unnecessary owner activity by placing responsibility on the contractor to plan the delivery process and quality controls. The contractor effectively becomes the hub for all coordination, documentation, and dissemination of critical

information with regards to project execution. Redundant management is thus minimized, and the owner's role becomes one of facilitating the contractor's efforts by providing any needed resources or information relating to project delivery.

Supply Chain Mentality. During preplanning, the contractor is asked to plan the entire project delivery and create a risk management plan that identifies risks to the plan. The focus of the risk management plan is on risks that are not under the contractor's direct control. This forces the contractor to operate with a supply chain mentality to identify and minimize project risk at the points of interaction and coordination between various project stakeholders. Such risks are identified and prioritized, aan action plan is created to minimize the risk from occurring, and a step-by-step response plan is generated for if these risks do in fact occur. All stakeholders approve the plan before signing the contract, which leads to a clear understanding of each party's roles and responsibilities, thus achieving proper alignment.

Transfer Risk to the Expert. Project responsibility and accountability is better allocated to the contractor by making the risk management plan a part of the contractor's contract. This enables the contractor to define its role on the project by identifying what risks are outside its control and accepting responsibility for all other foreseeable risks. During the project, it is understood that the contractor becomes the coordinating hub of all project activities. The contractor is responsible for documenting and distributing critical information about unforeseen risks that impact the project schedule, budget, or owner expectations of performance. The contractor is also held responsible for final project outcomes. Upon closeout, the owner gives a formal satisfaction rating of the contractor's performance, which then impacts the contractor's qualifications should they bid on future projects with the same owner.

Pre-Contract Planning Methodology

According to the above-mentioned principles, the Best Value Preplanning Model is process-oriented in that it is stresses optimal coordination of the various parties involved in project execution. The specific details of the operational plan are left to the experts – the contractor project team – but any necessary interactions between parties are clearly indicated in the plan. This coordination between parties is essential to communicate expected roles and responsibilities, which serves to minimize confusion and prevent project tasks from "slipping through the cracks." The process results in a fully detailed project plan prior to construction. Note that this does not necessarily mean that *every* issue has been completely resolved prior to construction, but it does require that the operational strategy is set and a specific action pathway has been coordinated with and agreed to by all participating parties. The Best Value Planning Model consists of six general steps:

Step 1: Process Education. The owner and related consultants provide educational resources for the selected contractor regarding the philosophy of the process, expected deliverables, and agenda of the initial kickoff meeting

Step 2: Kickoff Meeting. The contractor directs the meeting by presenting an overview of their project plan, discusses major risks and solutions, and sets the schedule of activities for the preconstruction planning period.

Step 3: Plan & Coordinate Deliverables. All required coordination activities are conducted to determine details of the project plan. This step has the longest

duration, and consists of meetings with specific owner stakeholders to provide needed information and requirements to the contractor's project team.

Step 4: Insert Deliverables Into Contract. The final functional plan is written in a formal manner and included in the contract documents. The plan includes the project scope (centered on interaction points between project participants), risk management plan, milestone schedule, financial agreement, and performance metrics.

Step 5: Summary Meeting. This meeting serves as a formal, final check that all parties agree to the plan before signing the contract.

Step 6: *Contract Signed.* Once all parties agree to the plan presented in the Summary Meeting, the contract documents are finalized, compiled, and signed.

ADVANTAGES OF PRE-CONTRACT PLANNING

While formal preplanning efforts that occur prior to the contract are uncommon within the industry as a whole, there are several key benefits of adopting this method. After years of testing, the following benefits have been documented to positively impact project performance.

Product Definition. By planning the entire project before entering into a contractual agreement, the owner and contractor both develop a clear understanding of what will be delivered. If at any point the contractor is unable to complete the preplanning or adequately resolve client concerns, the partnership may be broken. Yet if the contractor is able to complete the preplanning and both parties are inclined to continue with the project, the contract is signed. This results in an alignment of expectations, which is critical to project performance because the owner has a clear understanding of what they will receive and the contractor defines all project roles.

Heightened Accountability. After the contractor defines the contract in their risk management plan, they are measured against the plan throughout the project lifetime. The Best Value Model institutes a weekly risk reporting system wherein the contractor is responsible to identifying, documenting, and communicating any deviations to the plan. Impacts to the contract are documented in terms of budget, schedule, or owner expectations of performance.

Alignment. The roles of project participants are clearly defined during preplanning activities, placing the majority of risk and responsibility for delivering the project at the hands of the contractor. The contractor is also asked to define owner responsibilities by creating an "owner action item list" and planning a schedule that shows and owner key decision and input points over the project lifetime.

Increased Due Diligence. Holding planning activities prior to the contract forces greater due diligence. The contractor is driving towards signing a contract, which is only awarded once the project execution plan is in place. This inherently provides greater motivation to conduct a formal and thorough planning process.

LIMITATIONS OF PRE-CONTRACT PLANNING

Some weaknesses and limitations do exist in a model where the preplanning process occurs before the contract is signed.

Contractor Hesitance With Role Reversal. Even with training resources available to assist contractors in making the switch from traditional processes to a pre-contract

planning model, hesitancy may exist in bringing risks to the owner's attention. As the contractor dives into the project details and coordinates with client stakeholders, it is not uncommon for them to identify new risks or discrepancies that were not apparent in the bidding process. As the expert party, Best Value expects the contractor to identify any such risks, determine the optimal mitigation strategy (or strategies), and communicate potential impacts to the owner. Yet contractors can at first be uncomfortable with this role and unsure of how to communicate risks to the owner.

Tendency to Rush. Since the contract is not officially awarded until after the Best Value Preplanning Model is completed, contractors may attempt to speed the process up to secure the contract, which may result in shortcuts, loose ends, and non-specific risk mitigation strategies. Proper owner facilitation minimizes this limitation.

Educational Requirements and Resistance. Owners underestimate the amount of time and energy required to achieve a successful pre-contract planning process. Even if the owner has run the process many times, it should not be forgotten that the contractor group may be experiencing it for the first time and thus need significant support. Employee and contractor personnel resistance to change also exists. For the Best Value Model to work, all parties must be properly educated of the process, their roles, the expectations, and the overall purpose of the efforts.

Determining Completion. Determining when the preplanning process is complete and the partnership should move forward to contract may be unclear. The contractor, or even factions within the owner's group, may push to sign the contract. Yet before the contract should be signed, the plan must include a fully developed risk plan, clear scope definition, execution plan for delivering the scope of work, a milestone schedule (often with clear detail of what will be done in the first 30 to 90 days), and a client action item list (with all the information and support needed by the contractor). Both parties should review and agree to all parts before signing the contract.

Lack of Compensation. Contractors may be reluctant to spend too long a period of time working on preplanning activities in a situation where they have no cash flow since no contract has been signed. The owner must be sensitive to this aspect on a project-to-project basis. For highly complex projects that may required an extensive planning process, a source of funding may in fact be needed (this has been most commonly seen in selecting design consultants who submit detailed renderings).

PRE-CONTRACT PLANNING CASE STUDY

The Best Value pre-contract planning model was implemented with impressive results on a $21M design-build (DB) project for an advanced laboratory facility at the University of Alberta in Edmonton, Canada. The scope was for the repurpose of a cold storage facility into a hot lab including a cyclotron particle accelerator for radiopharmaceutical production in cancer treatment research. A design consultant produced bridging documents for use in the Request for Proposal and a value-based selection process was conducted to select a design build team. This was considered a highly complex project, with multiple funding sources, several end user groups, and various regulatory agencies. Once a DB team was selected, researchers from ASU provided training and support for running the pre-contract planning process. The planned duration for the planning process was three weeks, during which time the DB

team would address owner concerns, coordinate with various owner groups, generate a milestone schedule, and plan the execution strategy.

As a result of the pre-contract planning model, the DB team identified significant unforeseen risks that had the potential to impact the project with millions of dollars in additional costs as well as considerable schedule delays. The DB team communicated these unforeseen risks to the owner and requested that the preplanning process be extended from 3 weeks to a full 4.5 weeks in order to properly mitigate such significant risks before commencing operations. This process enabled the DB team to address the unforeseen risks and optimize the facility prior to signing the contract. Specific risk solutions were integrated into an operational project plan, including a clearly defined scope, milestone schedule for the project's duration, agreed-to base contract alternates (as value added items), client action items and deliverable dates, workflow process charts, an operational work plan, financial billing process charts, and a risk management plan wherein all risks were identified and prioritized, with actionable solution plans determined and potential impacts communicated. All deliverables were completed and agreed to prior to contract signing.
